command H.M.S. *Endeavour*. For a description of this vessel and a discussion of her rig see COOK'S SHIPS, below. The scientific staff of the expedition included Joseph Banks (q.v.), Daniel Solander (q.v.), and Charles Green the astronomer. The *Endeavour* left England on 26 August 1768; the observations at Tahiti were successfully carried out, and the Society group cleared on 9 August 1769. Cook now laid a course southwards in order to strike, if it existed, the southern continent that Dalrymple and others postulated to balance the masses of land in the northern hemisphere. On 2 September, however, having reached 40° S. lat. without seeing a sign of land, and meeting with very tempestuous weather, he turned NW. and after a while made SW. again in order to fall in with the land discovered and laid down by Tasman as Statenlandt. This he sighted on 7 October, and in the evening of the 9th landed on the shores of Poverty Bay, where four Maoris had to be killed before he could establish amicable relations with the rest—'the most disagreeable day my life has yet seen,' noted Banks. After a detour southwards past 40° S. lat. to Cape Turnagain, Cook followed the coast-line north-about, rounded the Three Kings at Christmas time, put into Queen Charlotte Sound (16 January), passed the strait afterwards named for him (8 February), and worked northwards till he once more saw Cape Turnagain. Having thus proved that section of New Zealand an island, he turned on his tracks, coasted the southern island till he could round Stewart Island (12 March), ran back northwards to Cape Farewell (25 March), and on the 27th put into Admiralty Bay in Cook Strait to refit. This rapid survey was one of Cook's most remarkable achievements. 'Never' says Wharton, 'has a coast been as well laid down by a first explorer, and it must have required unceasing vigilance and continual observation in fair weather and foul, to arrive at such a satisfactory conclusion; and with such a dull sailer as the *Endeavour* was, the six and a half months occupied in the work (2400 miles of coast) must be counted as a short interval in which to do it.'

The dates given above for Cook's New Zealand voyage require explanation, since from 7 October onwards several of them differ by a day from those usually accepted. Cook, sailing westwards across the Pacific, passed in the morning of 6 October the 180th parallel of longitude, at which the day is technically supposed to begin—so that if in 179° W. you are in Monday 1 August, by passing to 179° E. you automatically enter Tuesday 2 August, although no night has intervened. The modern practice is to make this change of date immediately on crossing an arbitrary line in the Pacific, which for the most part coincides with the 180th meridian. In Cook's day, however, the practice was to wait until the vessel reached some port in the eastern longitudes that was already on the chart; and Cook made the required change when he reached Batavia on 10-11 October 1770. To bring, therefore, his New Zealand and Australian dates into correspondence with those now current, it has been necessary to advance by one day dates mentioned between 6 October 1769 and 9 October 1770. But this only applies to the dating of events that occurred before noon; for in ships' logs of those days the new day began at noon, and what we should call the afternoon of, say, 6 October was reckoned as part of 7 October.

After leaving New Zealand Cook decided to return, as his *Journal* tells us, 'by way of the E. Indies by the following route. Upon leaving this coast to steer to the westward until we fall in with the E. coast of New Holland, and then to follow the direction of that coast to the Northward or what other direction it might take us, until we arrive at its Northern extremity; and if it should be found impracticable then to Endeavour to fall in with the Land or Islands discovered by Quiros.' This part of his voyage is narrated under EXPLORATION BY SEA. When the *Endeavour* reached England in June 1771, Cook was highly commended by the admiralty and appointed to command the *Scorpion*—an appointment vacated shortly afterwards, so that he never actually took it up. On 14 August he was presented to King George III (to whom he gave a copy of his *Journal* and some charts) and was handed his commission as commander. Cook, Banks, and Solander at this time were 'lions' in London society, and may there have met Hawkesworth, the voluminous and conceited writer who afterwards sophisticated Cook's straightforward narrative, and for many years fathered on him his own absurd speculations and pompous dissertations. But Cook had little time for writing; almost at once plans were made for a second voyage of South Sea exploration—Dalrymple and others having alleged that there was still room in the unexplored South Pacific for a continent—and two sloops, the *Drake* and the *Raleigh*, were selected (probably by Cook himself) for the expedition, rechristened *Resolution* and *Adventure*, and on 28 November 1771 placed under Cook's command. He took the *Resolution* (Tobias Furneaux being given the *Adventure*), and in his own words 'every standing rule and order in the Navy was dispensed with' so as to fit out the vessels suitably and fully. Banks had intended to go on this voyage also, but, considering the *Resolution* unsuitable for so long a trip, abandoned the intention. The officers were not sorry; Banks and his retinue of scientific workers would have taken up 'the chief accommodations of the ship,' and would probably have insisted on making Australia, and explorations by land, the central task of the expedition; whereas Cook and his officers, naval men all, were mainly interested in the laying down of new coast-lines. In Banks's place Johann Reinhold Forster (q.v.) joined the expedition as naturalist and his son Georg (usually known as George) as natural history painter. The ships left Plymouth on 13 July 1772, visited Table Bay (30 October to 22 November), ran down to the southern ice-fields—crossing the Antarctic Circle on 17 January 1773—and E. towards New Zealand. Furneaux, who had parted from Cook on 8 February, put in at Adventure Bay in Tasmania, and, running up the east coast in bad weather, persuaded himself that the shore-line was continuous from Tasman's Pillar to Cape Howe. When on 18 May he rejoined Cook (who had gone straight to Dusky Bay and thence to Queen Charlotte Sound) and reported his views about the Tasmanian shore-line, Cook thought of revisiting Tasmania to check this opinion; but Furneaux was positive, and the course of events did not guide the *Resolution* that way. The rest of 1773 was spent in criss-crossing the southern Pacific until there was no unexplored space left for a continent. In November Cook was back in Queen Charlotte Sound, but Furneaux did not arrive; on the

25th, therefore, the *Resolution* sailed again for the south, and on 30 January 1774 Cook reached the point 71° 10′ S. lat., 106° 54′ W. long., in a region of the Antarctic where no later explorer has penetrated beyond him. He next went hunting for a patch of land in 38° S. said to have been seen by Juan Fernandez; that illusion being dispelled, he made by way of Easter Island and the Marquesas for Tahiti, thence round the Fiji group to the New Hebrides, and thence on 4 September discovered New Caledonia and on 10 October Norfolk Island. On 18 October he was back in Queen Charlotte Sound again, and left it on 11 November to cross the ocean towards Magellan Strait along the line of 54° S. lat. Cape Horn was rounded on 29 December, South Georgia sighted on 14 January 1775, and Table Bay revisited (22 March to 27 April); then Cook, having circumnavigated the globe in fairly high southern latitudes and so proved that no continent existed outside the Antarctic Circle, turned homewards and reached England on 29 July. There he found Furneaux, whose crew at the end of 1773 had come into conflict with the Maoris at Queen Charlotte Sound, and who had then made his way back to England round Cape Horn, reaching Spithead on 14 July 1774.

For some months Cook was fully occupied with the preparation of his journals for publication. This time Hawkesworth was not employed, being dead. It was at first proposed that Reinhold Forster should collaborate with Cook, the navigator writing up the events of the voyage, the naturalist contributing a volume of scientific results; but Forster became involved in a bitter dispute with Lord Sandwich, the first lord of the admiralty, and in the end Cook wrote the whole book and had it edited by Canon Douglas of Windsor. Many of Cook's letters to Douglas are preserved in the British Museum, and disclose the explorer's fine character. During his stay in London Cook met Boswell, who reported to Johnson that 'that celebrated circumnavigator' with conscientious accuracy had set right many of Hawkesworth's exaggerations. On 29 February 1776 Cook was elected a fellow of the Royal Society, and on 7 March read to the Society a paper on his methods of preventing and curing scurvy—which constitute by no means the least of his services to Britain. While in 1758 the *Pembroke* lost from scurvy 29 men out of 400 in crossing the Atlantic (and did better, at that, than any other ship of the fleet), Cook in two voyages, totalling five years and eleven months, did not lose one. On the preceding 9 August he had been given post rank and appointed to command at Greenwich Hospital, but never took up his duties there. The admiralty was already projecting another expedition to the Pacific, and the *Resolution* was being refitted for the purpose; the proposed commander was Charles Clerke, who had been Cook's second lieutenant in the previous voyage, and the object suggested was the discovery of a passage from the Pacific to the Atlantic northabout. Clerke's appointment was due to the feeling that Cook deserved a long rest. When, therefore, on 10 February 1776 he volunteered to take command, his offer was gladly accepted, and Clerke was given the *Discovery* in which to accompany him.

On 12 July 1776 Cook in the *Resolution* left Plymouth Sound, with orders to sail via the Cape to New Zealand and Tahiti, and thence to the 'New Albion' of Francis Drake in about 45° N. lat., and work up the North American coast in the hope of finding a passage round the continent eastwards or round Asia westwards. The *Discovery*, which did not leave Plymouth till 1 August, joined him at Table Bay. On his way eastward he visited the Marion and Crozet groups and Kerguelen Island, and on 26 January 1777 put into Adventure Bay in Tasmania. On 12 February he was in Queen Charlotte Sound; then, by way of the Cook and Friendly groups (at the latter he observed an eclipse of the sun), he voyaged to Tahiti (spending from 12 August to 7 December in the group), and north to Christmas Island (25 December). Towards the end of January 1778 he discovered the Hawaiian group, which he named after Lord Sandwich, and thence made north-eastwards to New Albion (7 March). The summer was spent in a vain attempt to find a passage to the Atlantic, at first round Alaska, then westwards along the Siberian coast. On 29 August Cook reached a point which he named Cape North—probably Cape Ryrkain south of Wrangel Island, but could get no farther on account of adverse winds.

In September he turned south to winter in the Hawaiian group. On 25 November he reached Maui, where the natives were more honest and less suspicious than any he had yet met; in January he moved on to Hawaii itself, and spent about a fortnight (17 January to 4 February) at Karakakoa Bay in amicable intercourse with the natives, who brought him great quantities of supplies. Always thoughtful of native interests, he felt that he had made inroads on their stores, and had better move elsewhere; but when he put to sea gales sprang up, the *Resolution's* foremast gave way, and he was forced back again. For a reason that has never been discovered—the Bay natives may have felt that they were being exploited, and that it was someone else's turn to provide Cook with food—on this second visit the behaviour of the natives altered completely. They resented the landing of watering-parties, stole articles from the ship and even the cutter from its moorings at the anchor buoy, and roughly handled several inoffensive sailors. On 14 February 1779 Cook landed with an armed guard to visit the king and take hostages for future good behaviour. While he was parleying, the surrounding crowd of natives learnt that elsewhere in the bay a chief had been shot by one of his crew; a warrior threatened him insolently and threw stones at him, while another tried to stab his lieutenant, and stones were thrown at the guard. Cook fired at his assailant, and the marines at their tormentors; there was a scuffle, and the English party was driven back to the beach. While giving orders to his boat's crew Cook made the fatal mistake of turning his back on the natives, and was at once struck down and killed. His body, with those of four slain marines, remained in possession of the natives. During the 15th it was ascertained that the body had been in part used for a feast of chiefs. The natives still remaining hostile and insolent, their village was fired on the 17th; and on the 20th and 21st what was left of the body (part of the skull and scalp, the hands and the bones of the limbs) was brought down with solemnity to the beach by a chief, handed over to Clerke (who was now in command) and at sunset buried at sea.

On 16 March Clerke left the group to continue

explorations in the Arctic seas. The summer was spent in further attempts to pierce the ice-pack beyond Bering Strait, and at the approach of winter Lieutenants Gore and King (Clerke having died on 22 August) brought the two ships down the Asiatic coast to Macao (1 December) and thence via the Cape to England, which was reached on 4 October 1780.

In March 1779, when Cook was expected back in home waters from his third voyage, Benjamin Franklin (then minister to France from the revolted American colonies of England) instructed the commanders of American warships to consider Captain Cook a friend if he should meet any of them, although technically he was an officer of the nation with which they were at war. This graceful act needs mention particularly because Andrew Kippis, Cook's biographer in 1788, asserted that congress reversed this instruction as soon as it was known in Philadelphia—and the assertion, which has no foundation at all, has occasionally been resuscitated in recent times. Kippis in 1795 withdrew the statement unreservedly.

As a circumnavigator Cook stands unequalled —first for the magnitude of the work done in the time, second, for its accuracy, third, for the preservation of the health of his people. The three great voyages were completed with less hardship and loss of life than had hitherto been thought possible. Cook's efficiency as a commander, and his scientific and seamanlike qualities, were not alone responsible for this; his personality had more to do with it than his efficiency. What manner of man he was is shown by the fact that, during the many weary months when the ships' companies were confined together in a small vessel, the entries of punishments in the log-books were fewer than could be found in any other ships in the service at that period. No quarrels of any kind are recorded, except that with the Forsters during the third voyage; and they disagreed with nearly everyone, and convict themselves by their own version of their grievances.

Dumont D'Urville said of Cook that he was the 'most illustrious navigator of both the past and future ages, whose name will for ever remain at the head of the list of sailors of all nations.' Another great French contemporary, in the last spoken words of his which history has recorded, paid a graceful tribute to the great Englishman: La Pérouse, as he was leaving Botany Bay, said to Lieutenant P. G. King 'In short, Mr. Cook has done so much that he has left me nothing to do but admire his work.'

Cook's services had been recognized by promotion to commander upon returning from the *Endeavour* voyage, and to post rank on his return from the second voyage. The King now granted a coat of arms to his family, and a pension of £300 per annum to his widow. The Royal Society, which had already given him the Copley medal for his wise precautions against scurvy, struck a special gold medal in his honour and presented it to Mrs. Cook.

Cook's family soon became extinct in the direct line. On 21 December 1762, just before he sailed for Newfoundland, he married a Miss Batts of Barking in Essex. By her he had six children: three died in infancy, the others before the end of the century. James, the eldest, rose to command H.M. sloop *Spitfire*, and was drowned off the Isle of Wight in 1794. Nathaniel, the second, was in 1780, at the age of 16, lost in H.M.S. *Thunderer*, which foundered at sea. Hugh, the youngest of all, died in 1793, when only 17, at Cambridge, where he was studying for the church. Mrs. Cook, to whom (as well as to the three boys) George III had granted a pension, lived to be 93, and died at Clapham on 13 May 1835.

The value of Cook's discoveries along the Australian coast is recognized in several memorials. In Hyde Park, Sydney, there is a statue of him by Thomas Woolner, R.A., which was unveiled on 25 February 1879; and the landing-place at Kurnell on Botany Bay is marked by a tablet and a monument, near which the event is annually commemorated. Tablets are also placed on Cape Everard, near the hill first sighted from the *Endeavour;* on Mount Warning, the 'remarkable high peak' noted in Cook's log on 16 May 1770; and on Possession Island in Torres Straits, where he formally annexed the eastern coast to Britain.

For Cook's early life the best authority is Dr. George Young's *Life of Captain Cook,* published in 1836. Young was vicar of Whitby early in the 19th century. The various Cook logs, to be found in handy form in the *Historical Records of New South Wales,* are better material for a student than any books made from them. The *Life* by Kippis is often inaccurate. A *Life* by Arthur Kitson, published in 1911, is considered the best by many Cook students. For the first voyage (1768-1771) the final authority must be Cook's own autograph journal. Until 1921 it was supposed that this journal had perished, but three copies were known, one of which (the 'Corner' journal) is in the Australian Museum at Sydney. But in 1921 the original MS. was found among some Cook documents owned by H. W. F. Bolckow of Marton-in-Cleveland, having been apparently bought by his grandfather about 1835 from the executors of Captain Cook's widow. In March 1923 the journal and other documents were purchased at public auction by the Commonwealth and are now (1925) in the Mitchell Library at Sydney. The journal is being meticulously examined for any possible divergences from the previously known copies.

Cook's Ships. The first vessel in which Cook went to sea was the *Freelove,* a full-rigged ship of 341 tons, built at Great Yarmouth in 1746, owned by John Walker of Whitby and commanded by John Jefferson. He was on the books from 5 February 1747 till November 1748, when he joined the *Three Brothers* (same owner and master). In 1750 he was on the books of the *Mary* owned by John Wilkinson; in 1753 he was appointed mate of the *Friendship,* where he remained until he joined the navy. The *Freelove* was lost a few years after Cook left her, the *Three Brothers* in 1753, the *Mary* in 1762 and the *Friendship* in 1769. There is no truth in the often printed statement that the *Three Brothers* was afloat until late in the 19th century; the name was given to many Whitby ships. Cook's service in the Royal Navy was in the *Eagle* (June 1755 to June 1757), *Solebay* (July 1757 to September 1757), *Pembroke* (October 1757 to September 1759), and *Northumberland* (September 1759 to October 1763). He was then borne on the books of the *Antelope* and the *Tweed* while serving in small vessels on the survey of the Newfoundland coast. His first separate command as master was the *Grenville.*

The *Endeavour Bark,* as she was officially

named by the admiralty, was built at Whitby in 1764 by Thomas Fishburn for Thomas Milner, from whom the government purchased her. She was named by Milner the *Earl of Pembroke*, and was of 270 tons, square-rigged with an uncoppered bottom, of a build peculiarly adapted to taking the ground with safety—which was one of the reasons for Cook's selection of her. She is often described and pictured as barque-rigged; but Cook's log, and the custom-house entry at Whitby, prove that she was a ship. Many stories have been told of her ending, but all lack proof. When Cook was preparing for his second South Sea voyage, the *Endeavour* was on her way to the Falkland Islands as a store-ship; this is her last recorded service, and the admiralty sold her in 1775. A generally accepted version is that she ended her days on the beach at Newport in Rhode Island, U.S.A. The author of this story gives chapter and verse to show that a vessel named *Endeavour* was purchased from the British government in 1796. But Cook's *Endeavour* was sold 21 years earlier; moreover, there were 11 *Endeavours* on the Whitby register between 1749 and 1795, and more than one was sold during the same period.

The *Resolution* and the *Adventure* were built in 1770 by Fishburn of Whitby, and owned by William Hammond of Hull. Nothing certain is known of the fate of the *Resolution*; but John Barrow, while on his way to China in the Macartney expedition, saw a hulk at Rio de Janeiro which, he asserts, was this ship. Too many *Resolutions* were registered at Whitby to allow unqualified acceptance of this statement. The *Adventure* is known to have been lost in the Gulf of St. Lawrence in 1811. The *Discovery* was built at Whitby in 1774 by Langhorne for Herbert of Scarborough; nothing is known of her history, but E. W. Cooke, R.A., sketched a convict-hulk on the mud at Woolwich, and called his sketch 'The *Discovery*.'

An excellent authority for the Whitby ships in which Cook served is *The Ancient Port of Whitby and its Shipping*, by Richard Weatherill, published at Whitby in 1908. W.J.

For the build of the *Endeavour* two pictures have hitherto been usually accepted as evidence—the picture at Kurnell, taken from Weatherill's *Ancient Port of Whitby*, showing the *Earl of Pembroke* in 1768, and the alleged pencil sketch, by Buchan, of the *Endeavour's* hull, which is reproduced in vol. i of the *Historical Records of New South Wales*. The Kurnell picture has neither technical nor artistic merit, and in no way corresponds to the admiralty plan of the *Endeavour* that hangs alongside it.

The *Endeavour*

The Buchan sketch—if it is by Buchan at all, which is very doubtful—cannot be of the *Endeavour*: it represents an old vessel, probably a two-masted brig, of a build common 30 years before Cook sailed, and the only particular in which it corresponds to the authentic plans of Cook's ship (one at Kurnell, and two in the Pioneers' Club at Sydney) is the shape of the upper half of the stern—a shape common in North-country-built vessels designed for the Baltic timber trade. When Buchan died, in April 1769, the *Endeavour* was not yet five years old.

It has often been stated that Cook's ship was named the *Endeavour Bark* to distinguish her from another *Endeavour* that was already in the navy. The explanation is not convincing, since Admiral Wharton says that this other

Endeavour was a cutter; Laird Clowes, however, says that she carried 14 guns, and was lost in the West Indies in 1780. However this may be, Cook's ship was probably rated as a bark on account of her cat build (with straight stem and no figure-head), in which she differed greatly from the ordinary naval vessels of the day. F.J.B.

Cook, Sir Joseph, born at Silverdale in Staffordshire in 1860, began life in a coal-mine at the age of nine. Migrating to Australia in 1885, he worked in the mines at Lithgow until 1891, when he was sent to parliament from the Hartley electorate as one of the labour party, then making its first appearance in the legislature. In 1893 the party, declaring itself neutral as a whole on the fiscal question, split up when matters connected with the tariff were under discussion, and Cook was chosen leader of the freetrade section. In March 1894 the party conference confirmed a proposal that every labour candidate should bind himself not only to support the party platform, but to vote on all questions involving the fate of a ministry as the majority of the parliamentary caucus might decide. Cook, refusing to take such a pledge, left the party, and on 3 August was taken into Reid's ministry as postmaster-general. In 1898 he was made minister for mines, and held that post until Reid was thrown out of office in 1899. He held the seat for Hartley as long as he remained in New South Wales politics, and built up a reputation as an honest administrator, not specially effective in debate but always to be depended on in emergencies. In March 1901 he entered the Federal parliament as member for Parramatta, which constituency he continued to represent for 20 years. In the first parliament he was merely one of the rank and file of the freetrade opposition, but established a reputation for 'fighting' speeches. When Reid late in 1905 gave up all hope of effecting a coalition, he determined to make his opposition an active and felt influence, and substituted Cook for Dugald Thomson as deputy-leader. From that time Cook was the real head of a critical and persistently fighting opposition. When Reid resigned in 1908, Cook's services to his party outweighed the prestige of John Forrest; he was elected leader, and joined Alfred Deakin in the coalition ministry of 1909-10, taking the portfolio of defence and helping his senior colleague to obtain the establishment of an Australian naval 'unit' (see Naval Defence) and to procure the services of Lord Kitchener as adviser in the construction of a compulsory training scheme (see Military Defence). When the coalition was driven from office in 1910, Cook gradually replaced Deakin in all active debate, and, succeeding him as leader in 1913, became prime minister in that year. Again in opposition from 1914 to 1917 (but giving the then ministry full support on all war measures), he in 1917 joined a coalition ministry as minister for the navy, was one of the Australian representatives at the Versailles peace conference, returned to become treasurer of the Commonwealth, and in 1921 left politics to take the position of high commissioner in London. (P.C., 1914; G.C.M.G., 1918.)

Coolabah (also Coolibah, Koolibah and Coolybar), aboriginal name of *Eucalyptus microtheca,* common in the interior of Australia from the north-west to the Murray and the Cloncurry. It grows along water-courses, and in the region neighbouring the Gulf of Carpentaria is known as 'flooded box.' On the arid inland plains its presence is a sign of water, if not on the surface, at least not far below it, and it is often used by travellers as a shelter for camping. It was on a coolabah that Brahe carved the word 'Dig' to indicate to Burke and Wills (see Exploration by Land) where he had buried their stores.

The name is also loosely used for other eucalypts (*E. conica* and *E. intertexta*), and sometimes for a relative of the eucalypts, *Angophora melanoxylon.*

Cooper, Sir Charles (1795-1887), born in March 1795 at Henley-on-Thames, and entered as a student at the Inner Temple in January 1822, was called to the bar on 9 February 1827, and practised on the Oxford circuit. In 1838 he was appointed a puisne judge of the supreme court of South Australia, in succession to Sir John Jeffcott; he reached Adelaide in March 1839, and for 10 years was the only judge in the colony, conducting unaided three courts—civil, criminal and insolvency. On 26 March 1849 he was appointed the first chief justice of the colony. Apart from his judicial work he occasionally acted as draftsman of important statutes, among them the first South Australian insolvency act. He was an intimate friend of Charles Sturt, who named Cooper's Creek after him, and protested vehemently when in 1859 the Sydney survey office proposed to alter the name to 'Kennedy River.' Owing to ill-health he retired on 26 November 1861 and returned to England; he died at Bath on 24 May 1887. (Kt. Bach., 1857.)

Cooper, Sir Daniel (1821-1902), born at Bolton-le-Moors in Lancashire on 1 July 1821 and educated at University College, London, received his early mercantile training with a firm trading at Havre in France and in 1843 returned to Sydney (where he had lived with his parents for some years in childhood) to join his father's firm of Holt and Cooper, which in 1851 became Cooper & Co. In 1849 he was elected to the old New South Wales legislative council by the counties of St. Vincent and Auckland, but retired at the dissolution of 1851, visited England on several occasions in the next few years, and gained prominence as the originator of an Australian fund to relieve distress caused by the Crimean war. In March 1856 he was elected to the new legislative assembly by Sydney Hamlets, held the seat till April 1859, and then transferred to Paddington; he was speaker of the house in the three parliaments during which he served, but on 31 January 1860 resigned the position on account of failing health, and retired from politics at the end of the year. From that time till his death on 5 June 1902 he resided in London.

Cooper's wealth, acquired partly from commerce and partly from investments in land, was largely spent on philanthropic objects in England and Australia. For the university of Sydney (of which he was a senator from 1857 to 1861) he created a fund from which one graduate and three undergraduate scholarships are now provided; but his chief benefactions were connected with the distress caused in Lancashire by the American civil war, and for his gifts and services in that crisis he received a baronetcy. On several occasions in his later years (e.g. in 1888 and from 1897-9) he acted as agent-general for New South Wales. (Kt. Bach., 1857; Bart., 1863; K.C.M.G., 1880; G.C.M.G., 1888.)

Coots. See Rails.

Copper. Ores of this metal are said to have been found near Macquarie Harbour in Tasmania on 20 April 1827, and somewhere in New South Wales during January 1829; but these discoveries were not followed up, and may, indeed, have been mere rumours. The first certain discovery of copper in Australia was made by Francis Dutton and Edward Bagot at Kapunda, 50 miles north of Adelaide, in 1842; samples of the ore were sent to England, and on the receipt of a favourable report a mine was opened and miners were engaged both on wages and on tribute. In 1845 a shepherd named Pickett found outcrops at Burra Burra, about 100 miles north of Adelaide; on the biggest of these was established the famous Burra Burra mine, which in 30 years produced almost five million pounds' worth of copper, and paid £800,000 in dividends on a nominal capital of £12,320, none of which was ever called up. In New South Wales the metal was mined for in 1844, and in 1845 deposits at Molong and Canowindra were exploited; during the next 20 years a large number of mines were worked at various places in the western foothills of the main range, chiefly in the neighbourhood of Orange. In Western Australia the excitement caused by the South Australian discoveries caused a good deal of searching, but the first actual finds were made on 18 December 1846 in the area south-east of Perth, and the first serious attempt to mine for copper followed on Augustus Gregory's discovery of the ore at Northampton (near Champion Bay) in 1848. Owing, however, to lack of labour and remoteness from Perth, mining was carried on in a very perfunctory fashion, and work was discontinued as soon as the lodes began to contract. In 1860 mines were opened at Wallaroo and Moonta in South Australia, and in 1862 at Peak Downs and Mount Perry in Queensland; in Victoria also several small deposits were located, but the only one of any size was at Walhalla in Gippsland. In Tasmania no discoveries of commercial value were made until 1890, when the Mount Lyell goldfield, north of Macquarie Harbour, was found to contain plentiful supplies of native copper.

The principal fields in Australia where copper is being, or has of late years been, mined are situated near Cloncurry and Mount Morgan in Queensland, Cobar in New South Wales, Wallaroo and Moonta in South Australia, West Pilbara in Western Australia, and Mount Lyell in Tasmania. At Cloncurry ore was discovered in the late sixties; for a few months in 1886 attempts were made to smelt the ores locally, but with that exception they were shipped south until 1909, when the Mount Elliot Company opened reduction works at Selwyn; similar works were opened at Kuridala in 1911 and at Mount Cuthbert in 1917. At Mount Morgan, which was worked for many years solely as a gold-mine, copper-smelting began in 1906, the blister copper being sent to Port Kembla in New South Wales for final treatment. The collapse in copper prices after 1918, followed by repeated strikes, resulted in the closing down of this mine in 1921-2, and a second closing-down is (1925) imminent. At Cobar, where copper was discovered in 1869, the richer surface ores were at first sent by team to Bourke and shipped down the Darling to smelting works at Port Adelaide. From 1889 to 1893 operations were suspended, but in the latter year the chief mine was reopened on tribute and blast furnaces erected; as a railway to the area had been opened in 1891, success was immediate and prolonged. In 1920, however, most of the mines were sealed down and the plants dismantled. At Wallaroo and Moonta operations have been more continuous than anywhere else in Australia; the Moonta Company was the first in Australia whose dividends accumulated to a million pounds, and in 63 years the two mines have produced nearly £20,365,000 of copper and paid over £2,600,000 in dividends. The reduction works are at Wallaroo, the mines now worked being at Kadina and Moonta. In Western Australia the original Northampton field gradually became a source of lead rather than of copper, and the principal copper-field of late years has been on the West Pilbara goldfield, S. of Roebourne, the next in importance being the Phillips field on the Bight, W. of Esperance. The Mount Lyell field in Tasmania, whose copper resources began to be developed in 1893, was in 1901 producing nearly half the copper in the Commonwealth, but after 1906 came second to the great Queensland mines. The following figures will show the relative importance of the various fields, and the disastrous effects of the post-war collapse in prices:—

	1917 TONS	1919 TONS	1922 TONS
Queensland (chiefly Cloncurry and Mount Morgan	19,062	9997	5104
New South Wales (chiefly Cobar)	6576	1460	625
South Australia (chiefly Wallaroo and Moonta)	7213	2517	1185
Western Australia (chiefly West Pilbara)	1501	459	1012
Tasmania (chiefly Mount Lyell)	6616	5071	5616

The value of the Commonwealth copper production for these years was nearly five millions sterling in 1917, under two millions in 1919, and not quite £850,000 in 1922.

Methods of Production. Copper produced in Australia can be broadly classified as derived from the following sources:—(*a*) mines (or group of mines) in which the ore supply is sufficiently large to maintain its own smelting plant; (*b*) mines in which the ore supply is not sufficiently large to comply with (*a*), but which maintain a concentrating plant and forward the concentrates to customs smelters for treatment; (*c*) small mines operated and owned by private individuals, the ore mined from which is generally hand-picked and sold to customs smelters. The ore produced from this class of mine is, in the main, oxidized ore.

Metallurgically considered the ores of copper can be classified under two main groups, (1) oxidized and (2) sulphide ores; in the latter the gangue may be (*a*) basic, (*b*) siliceous. Generally speaking the ores of group 1 are not smelted direct, owing to the excessive cost of the coke required in the smelting. They are in general smelted along with the ores of group 2 *a*. Ores of group 2 *a* are smelted direct. Those of group 2 *b* are in general concentrated by crushing and separation of the gangue from the metallic particles by treatment in jigs, concentrating tables, etc., followed by flotation. This treatment gives (*a*) concentrated metallic values, and (*b*) worthless tailings comprising the major portion of the siliceous gangue of the original ore.

The economic point at which an ore should be concentrated is largely dependent on the cost and supply of basic fluxes. Silica alone, at ordinary smelting temperatures, may be regarded as infusible; with a correct proportion

of limestone and ironstone it forms a mixture readily fusible within the range of smelting temperatures. Concentrates are delivered from the mill in a form not suitable for the blast furnace. The Australian practice is to sinter the concentrates in Huntington-Heberlein pots or on Dwight-Lloyd sintering machines. The object is two-fold, to agglomerate the fine concentrates, making them suitable for treatment in a blast furnace, and to eliminate the excess sulphur. When once the ores of group 2 *b* have been concentrated, and the resulting concentrates sintered, they are as amenable to treatment in the blast furnace as the other groups. In the blast furnace the ore, fluxes and fuel are in intimate contact, and combustion is intensified by the use of a forced blast of air. Its products are a small, rich, metallic portion (matte), and a large worthless portion (slag). In Australian practice the average grade of matte carries about 40 per cent of copper, as well as any gold or silver that is in the ore.

The next process is to free the copper from the iron and sulphur. This is accomplished by placing the molten matte in a vessel so constructed as to allow a blast of air being passed through the molten charge; silica (in the form of siliceous ores) is added, and the iron, oxidized to ferrous oxide, combines with the silica, forming a slag which is poured from the charge. The sulphur passes off as sulphur dioxide. When this process is complete only copper and precious metals (if any) remain; this is known as blister copper, and is about 99 per cent pure. If it contains gold or silver values, it is then electrolytically refined. It is moulded into special sheets (anodes), which are suspended in an electrolytic cell alternately with sheets of pure copper (cathodes). The electrolyte is an acidulated solution of copper sulphate. On passing a current through the cell the copper of the anode is deposited on the thin sheet of cathode copper; gold and silver fall as a sludge to the bottom of the cell, and are separately refined. The cathodes are remelted, and cast into ingots suitable for commercial use. O.H.W.

Coppin, GEORGE SELTH (1819-1906), born at Steyning in Sussex on 8 April 1819, was the son of a physician who took to theatrical management. The boy began as an infant prodigy, playing the violin in public when only four years old and acting a few years later. By 1841 he had stage-managed at Woolwich, played minor Shakespearian parts at Sheffield, and starred in low comedy vaudeville at Manchester and Dublin. Eloping with an American actress, he reached Sydney on 10 March 1843, secured an engagement at the Victoria Theatre, and lost all his savings by an unlucky speculation in hotel-keeping. In 1845 he 'starred' in Hobart and Launceston (January-May), and in Melbourne from June onwards; in 1846 he moved to Adelaide, made a second fortune there, and lost it all in copper-mining speculations. In 1851 he tried gold-digging for a fortnight, and then made a third fortune on the stage in Melbourne and Geelong. A short visit to England in 1854, during which he appeared at the Haymarket in London and at the bigger provincial theatres, resulted in the engagement of G. V. Brooke for a tour through Australia. Returning to Melbourne, Coppin for another 10 years resumed his habit of making money in the theatre and losing it outside. In 1855 he opened in Melbourne the new Olympic Theatre, often known as the 'Iron Pot'—a galvanized iron structure which had been made for him in Birmingham. In 1856 he joined Brooke (whose tour had proved very successful) in purchasing the Theatre Royal at Melbourne, which he used for the first grand opera season ever given in Australia. In 1863 he brought the Keans to Australia, paid all his debts with the profits of their tour, then accompanied them to America, but was back in Melbourne by the beginning of 1866. In 1881 he retired from the stage, having built six theatres in Australia during his career and introduced more than 200 artists.

Side by side with theatrical work he found time for politics. In 1858 he was elected to the Victorian council from the south-western province, and was an ardent advocate of federation and intercolonial freetrade. Resigning when he went to America in 1864, he was sent 10 years later by East Melbourne to the assembly, and held the seat until 1889, after which the Melbourne province elected him unopposed to the council. Never a partisan, he was very popular in both houses, but was not taken seriously as a politician. In other ways, however, he did good public service. He was one of the founders of Sorrento near Port Phillip heads, of the Victorian Humane Society, and of the Old Colonists' Association; he persistently advocated acclimatization, and himself introduced English thrushes. He died at Melbourne on 12 March 1906.

Coprosma, a genus of the family Rubiaceae, consisting of erect, prostrate, or creeping shrubs. The calyx is toothed or lobed; corolla-tube short with 4 or 5 (rarely 6) lobes; fruit a berry-like drupe, with 2 stony seeds furrowed on the inner face; flower usually insignificant, in clusters, often with a fetid odour. The sexes occur on different plants. *C. hirtella* has a small edible fruit with a disagreeable flavour. *C. Billardieri* has a small round drupe, which the early Tasmanian settlers made into puddings. Both are ornamental shrubs.

Copyright in Australia is governed by the Imperial act of 1911, of which a detailed account is given in *Chambers's Encyclopaedia,* vol. iii. But this act and the orders in council which regulate foreign copyright within the Empire were primarily devised to meet British needs and conditions, and conditions in Australia are in some respects so different as to impose on publication within the Commonwealth hardships worth discussion.

The provisions of the act of 1911 with regard to the meaning, duration and ownership of copyright, so far as British subjects are concerned, involve no hardships, and probably for this reason it was adopted as a whole by the Commonwealth parliament in 1912. Nor are there any Australian objections to the extension of British (and therefore of Australian) copyright to other members of the Berne Copyright Union, since the basis of that Union is that each member puts authors belonging to other members on the same footing as its own authors. But with regard to the United States, which stands outside the Berne Union, the position is different. An American author or publisher secures copyright throughout the British Empire (and therefore, of course, in Australia) by 'publication'—that is, by registering his book and offering it for sale—anywhere in the Empire or in any country that adheres to the Berne Union. But an Australian author or publisher can secure copyright in the United States only by conforming with the American law which requires that all books in

the English language must be set up, printed and bound within the States, within sixty days (the period of grace may be at most extended to six months) of its original publication elsewhere. This means that, whereas the American author secures Australian copyright by a mere formality gone through in London or any other part of the Empire, the Australian author must go to the great expense of producing a separate edition of his work in the United States.

This law was brought into being under pressure from labour unions in the States in order to ensure local production. The view of high authorities in America may be gathered from the 1919 *Report of the Register of Copyrights* at Washington:—

> The remedy indicated to benefit both American and British authors is such action as will confer copyright security in all the English-speaking countries from the day the work is first published in any one of them. The statutory requirements of publication and manufacture should be subordinated to this secured protection of the author's literary and artistic property.

With such an official acknowledgment of the existing injustice it should not be difficult to find a remedy in exact reciprocity—imposing on authors of non-British nationality the same conditions of copyright as their nation imposes on Australian authors. The parliament of the Commonwealth can do this by substituting for the adopting act of 1912 a new act substantially identical with the Imperial act, but applying to American authors the conditions of the American law.

Coral, the name given to members of the Coelenterata that protect themselves with a limy skeleton. A few Hydrozoa have this habit; all true corals, however, belong to the class Actinozoa, and are merely sea-anemones that have acquired the habit of secreting (*a*) a limy outer wall, and (*b*) a series of internal radiating limy plates. They are known as madrepore corals. When formed by a solitary polyp, the resulting cup-coral is known as a corallite; in the majority of species a large number—sometimes many thousands—of corallites combine to form a corallium, the skeleton of the entire coral-colony.

Some coral-animals, like the majority of sea-anemones, are solitary; the well-known Mushroom-coral (*Fungia*) is an example. It takes its name from its resemblance to the head of an expanded mushroom turned upside down. Solitary corals are found in pools of the reefs surrounding many Pacific islands, and also on the Great Barrier Reef. When the polyp is expanded, it might easily be mistaken for a big sea-anemone; on being disturbed, however, it immediately shrinks back upon its base, ejecting all the water with which its tissues were filled, and revealing the presence of the hard, radiating coral beneath. New mushroom corals are produced as buds thrown off from the parent. These buds attach themselves, and secrete a foot-stalk to which they remain affixed for the earlier stages of their existence. Ultimately they fall from their stalks, and lie loosely on the sea-bottom after the manner of their parents. A common solitary form is the fan-shaped Crisp-coral (*Flabellum*), which has been found to occur even in the cold waters off southern Tasmania; another is the little conical *Conocyathus*, frequently found at Watson's Bay in Port Jackson.

The great majority of coral-polyps form aggregates or colony-stocks of numerous units, brought about by repeated budding, or by the subdivision without complete separation of a single individual. The huge coral-masses commonly known as madrepores, out of which coral islands and reefs are constructed, all commence as a single coral-animal, with its contained skeleton similar to that of a mushroom-coral, although in every instance much smaller. The buds in these instances remain attached to the parent. If they spread out laterally, they build up by accumulation the large, flattened, subspherical or globose masses known as star-corals (*Goniastraea* and *Favia*), and brain-corals (*Meandrina* and *Coeloria*), the surfaces of which look like a series of deeply excavated valleys. Where, on the other hand, the budding is terminal or oblique, branching tree-like growths—such as the stag-horn corals, with their innumerable allies and variations—are produced. Isolated patches of coral (*Plesiastraea*) occur in parts of Sydney Harbour, where they appear like green moss when seen alive on the overhanging edges of rock-pools. Three species of *Plesiastraea* apparently occur in the extra-tropical seas of Australia. Their occurrence in South Australian waters must be regarded as a remarkable instance of a characteristically tropical type living in low-temperature seas. They are coral-reef forms, and members of a family which are essentially coral-reef builders; but even on the reefs, apparently, they do not grow to any large size—which makes their occurrence in huge proportions in extra-tropical waters all the more remarkable.

Coral-reefs and Coral-islands.—Coral-polyps play an important part in the economy of nature. Reef-building corals are confined to the tropical parts of the Atlantic, Indian and Pacific Oceans, flourishing only where the lowest temperature does not sink below 68° F. Thus their northernmost limits are the Bermudas in the Atlantic, and southern Japan in the Pacific; their southernmost limits Rio and St. Helena in the Atlantic, Queensland and Easter Island in the Pacific; in other words, they extend to about 30° on each side of the equator. Moreover, they have a curiously limited vertical distribution, flourishing only from high-water mark down to a depth of about 20 fathoms, but not lower. In the Pacific Ocean the southern limit should be extended to include Lord Howe Island (q.v.), the most southern of the outlying islands on the east coast of Australia; its western shore is protected by coral growths forming a fringing reef. When reef-building corals first take possession of a new shore, they grow upwards from the shallow bottom and outwards into the surf. During severe storms they are wrenched from the bottom and rolled about by the action of the waves, the larger fragments of their limy skeleton being finally thrown back towards the land, forming shoals, and sometimes rising in a beach a little above sea-level; the finer particles are carried off shore and strewn over the sloping bottom towards deep water. The reef thus broadens, forming a fringe close along the shore-line. At this stage it is called a fringing reef. A fringing reef is broadened by the outward growth of the corals, and the submarine slope is built forwards by the supply of coral fragments; at the same time water supplied by rain, by streams from the land, and especially by surf rolling over the reef, slowly dissolves and washes away the inner part of the reef, where living corals are few or wanting. Thus the reef may come to be separated from the land by a shallow lagoon, and in this manner a fringing reef may change to a barrier reef.

At first sight a coral reef is very disappointing; the surface, composed of dead and broken coral, presents a long vista of heaps of discoloured fragments that have been piled up by the action of the waves. As the coral grows nearer to the surface of the sea, portions become exposed to the direct heat of the sun when the reef is uncovered at low tide, and under these circumstances the coral soon dies. The branched forms (stag-horn coral) die first, and their broken, limy skeletons compose the main bulk of the reef. In the deeper pools left by the receding tide, and on the outer edge of the reef, flourish the living corals, which are of extreme beauty and of the utmost interest. As these continue to grow all round the edges in the deeper water, they are continually enlarging the size of the reef. There are many different kinds, from the branching stag-horn coral to the great rounded masses of the brain-corals, which may be three feet or more in diameter. The colours of living corals are brilliant and diverse, one branching variety being a beautiful light green, with the end of each branch terminating in a bright yellow tip. Some show various shades of pink, others a brilliant blue.

If a reef is depressed faster than the corals can grow upwards, the depth of water above it will increase beyond that in which reef-building corals can live. Then the polyps are 'drowned' and the reef is 'dead.' When, however, a slow depression takes place, it may be counteracted by the upward growth of the reef-corals; the reef will be preserved, and may even increase in size by outward growth during depression. At the same time the lower slopes of the island which the reef first fringed will be submerged; as the slow depression continues, the central island may finally disappear, leaving only an encircling reef of oval or irregular outline around the lagoon. Such reefs are called atolls or coral-islands.

Our knowledge of the formation of coral-reefs and coral-islands is based mainly on the work of Darwin, who conceived and expounded the subsidence theory, and on the subsequent researches carried out by Edgeworth David (q.v.) on the island of Funafuti in the Ellice group, where a successful boring was made to a depth of 1114 feet. The material from the bore was found to be coral-formed limestone, thus proving the justice of Darwin's assumption as to the nature of the substratum, and giving support to the subsidence theory as applied to this particular island. Supplementary work has been carried out by Charles Hedley, Griffith Taylor, and E. C. Andrews on the Great Barrier Reef of Australia, and by Mayer on the reefs of Murray Island in Torres Straits. In recent years the opinion has been expressed by several authors that the subsidence theory cannot account for the formation of all the atolls and barrier reefs that have now been investigated, and alternate hypotheses have been suggested to account for particular cases.

See Darwin's *Structure and Distribution of Coral Reefs* (1842), Dana's *Corals and Coral Islands* (1875), *The Atoll of Funafuti* (report of the coral reef committee of the Royal Society, 1904), and Wood-Jones's *Corals and Atolls* (1912). The work of Hedley and Taylor referred to above is summed up in 'Coral Reefs of the Great Barrier, Queensland' printed in the 1907 *Report* of the Australasian Association for the Advancement of Science. E.A.B.

Coral Cod. See ROCK COD.

Coral-fishes, members of the family Chaetodontidae, in which are included some of the most brilliantly ornamented of all fishes; their colours are often arranged in extraordinarily bizarre patterns which evidently serve as recognition-marks to enable an individual of any one species to find its fellows. They are plentiful among coral reefs, where the colours of almost every living organism may be gaudy to the point of garishness, but their striking contrasts of blue and orange, black and gold, or scarlet and green, render them conspicuous even in such gorgeous surroundings. The young of many have large black eye-spots (ocelli) upon their fins, which apparently afford them protection by scaring away larger enemies; a foe in search of food observes what seems to be a large eye peering steadily at it from among the coral branches, and, suspecting danger in such an unblinking gaze, makes off without further investigation. If this be correct, as may reasonably be supposed, such ocelli must be of great value to small and helpless fishes; and it is noteworthy that the young of many different kinds have them well developed, whereas they are usually lost as the fish grows and, being better able to look after itself, no longer needs them.

Chaetodons are mostly too small to be of value as food-fishes, though some reach a length of 12 inches. The snout is often produced into a longer or shorter beak, and the jaws are provided with projecting hair-like teeth to enable the fish to pick out from the crevices of the coral the small organisms which form its food. A large number of species occur in the tropics, and a few stray southward into cooler zones; several specialized members of the family are permanent residents of the southern coasts of Australia. The batfishes and butter-fishes are tropical relatives of the coral-fish, and the 'old wife' and mado are cooler-water allies. All these are discussed separately. A.R.McC.

Cordia, a large (chiefly tropical) genus of the family Boragineae, three species of which are indigenous to north-eastern Australia. *C. myxa,* an ornamental tree with large, nearly orbicular leaves, extends to tropical Asia and is cultivated in many lands; it is the 'Sebesten Plum' of India, where the tender young shoots are eaten either as a vegetable or pickled. The kernel, which tastes like a filbert, is also eaten. From their mucilaginous properties, combined with a degree of astringency, they have been employed as pectoral medicines under the name of Sebestens. The bark is used as a mild tonic. The wood which is grey to light brown in colour, and soft, is said to have furnished the timber from which Egyptian mummy-cases were made. It is used in India for boat-building, and to make covers for Burmese cheroots. The viscid pulp of the fruit is made into birdlime; the kernel yields a marking ink.

Corella. See COCKATOOS.

Corkwood. See DUBOISIA and ENDIANDRA.

Cormorants, large aquatic birds belonging to the family Phalacrocoracidae and better known in Australia as shags. There are five species of which one, the Black Cormorant (*Phalacrocorax carbo*) is the same as the cormorant of Europe; the other four are peculiar to the Australian region. Two large, white-breasted species are found on the sea-coasts, one of them (*P. fuscescens*) being confined to Tasmania and the southern coast of Australia, the other (*P. varius*) occurring all round the

Australian coast-line and extending to New Zealand. Two other much smaller species usually frequent rivers, swamps, and lagoons; both of these occur also in the Malay Archipelago—one (*P. ater*) is entirely black; the other (*Microcarbo melanoleucus*) has a white breast.

Pied Cormorant
(*Phalacrocorax varius*).

Shags feed on fish, crabs, and crayfish, and there has been much discussion as to whether they should be destroyed in the interests of fishermen. Available evidence seems to indicate that on the sea-coast and large coastal estuaries they feed mainly on crustacea and slow-swimming, non-edible fishes, and thus are of benefit by destroying enemies of the principal food-fishes; on the rivers and swamps, however, where even rapidly swimming fish have little chance of escape, they undoubtedly destroy all kinds of fish. They are of benefit in irrigation settlements, as they feed on the freshwater crayfishes that make holes in the banks of irrigation channels.

W.B.A.

Correa, a genus of the family Rutaceae, consisting of shrubs endemic in Australia. The flowers are large, showy red, yellow, white, or green; calyx cup-shaped, 4-toothed or lobed; petals 4, adhering in a cylindrical tube (in some species separating as the flower expands). *C. alba* is a coastal sand-dune shrub with creamy flowers, especially adapted to withstand the harsh conditions of such a habitat, and valuable as a sand-binder. It was known as 'Cape Barren tea' in Tasmania, its leaves being used by sealers as a substitute for tea. It seeds freely, and is easily propagated. *C. speciosa* (Native Fuchsia, which name is also ineptly given to *Epacris longiflora* and to a species of *Eremophila*) is a pretty shrub with varicoloured flowers, shading from red to green, and in some varieties from yellowish-green to white.

Cape Barren Tea.

Corrodentia. See INSECTS.

Cost of Living. The average cost of living for a family or other group of persons obviously depends upon (*a*) the number of each age and sex included therein, and (*b*) the price of the commodities used by them. In Australia two comprehensive enquiries have been made into this subject by means of budgets. In the first 1500 people voluntarily undertook to keep records for a whole year—July 1910 to June 1911 inclusive; books were supplied to them, but only 212 satisfactory returns were received. In the second instance 7000 volunteers agreed to keep records for four consecutive weeks in November 1913; 7000 books and sets of instructions were supplied, but only 392 satisfactory returns were made. The returns gave the cost of living for families receiving incomes under £200 per annum, and for those receiving over £200 per annum. Reduced to 1911 prices by means of price-indexes, the various amounts of expenditure are shown in the table hereunder. The families consisted of 588 husbands, 592 wives or widows, 1635 children of all ages, and 216 other dependents—3031 persons in all. The table constitutes, therefore, an illustration of the actual expenditure in 1911 of a sufficiently large number of people to furnish a satisfactory indication of the distribution of expenditure for rent, food, clothing, fuel and light, and other items. The use of price-indexes to correct the 1913 results (both as regards expenditure and income received) so as to agree with the 1911 basis makes all the elements of expenditure comparable, as well as the income received. It will be seen that the expenditure in lines 2 and 3 is alleged to exceed the income received.

Marked differences were found to exist between both expenditures and incomes in 1911 and 1913. These are explained by the fact that the 1911 returns were received from widely representative sections of the community, and the 1913 returns mainly from members of trade unions.

Once the budget for a family of a given size has been ascertained for any one period, that for any other can readily be found by taking account of the relative changes in the price of commodities since the original investigation was made. A record of such changes is, therefore, essential; and it serves a wider purpose also, inasmuch as it affords a means of measuring the varying relation between the unit of money—the pound sterling—and the commodities which money can purchase.

The actual cost of living will of course vary with the quantity, quality, and price of the commodities used. Changes in quantity and quality constitute alterations in the 'standard of living:' these may be altered by the in-

dividual. Changes in price, on the other hand, he cannot control. In order to measure that part of the total change which is due solely to the altered purchasing power of £1, it is necessary to see that the 'standard' or 'regimen' used to ascertain the variation in purchasing power is the same for each occasion. Practically, the consideration must be restricted to such commodities as are identifiable in respect of quality, while the quantities are kept the same throughout. In this way the results given hereinafter have been obtained. The relative quantities used, ascertained from five years' records, are called 'mass-units;' it is, of course, immaterial whether these units are doubled, trebled, or multiplied by any number whatever, or whether they represent a day's, week's or year's supply. Whatever commodities and quantities are adopted at one date, however, must be used also at the date to be compared therewith. The entire group of commodities so used may be called the 'regimen' or 'composite unit' adopted. The principle of comparison is simple. If the composite unit costs at one date £10,

AUSTRALIAN EXPENDITURE ON LIVING.

Group.	Average No. in Family.	Date of Enquiry.	No. of Budgets.	Expenditure. Rent.	Food.	Clothing.	Fuel and light.	Other Items.	Total	Income Average.

at another £12, and at a third £13. 5s. 0d, then what 1000 pounds, shillings or pence would buy at the first date could be bought for 1200 of the same money-unit at the second date, and for 1325 at the third date. If the first date is taken as a reference date, and 1000 as the initial price-index, the 'price-index numbers' of the second and third dates are 1200 and 1325. Price-index numbers, therefore, are a measure of the reciprocals of the value of the pound sterling, or of any other unit of money we choose to adopt.

* The weighted average may be taken as representing the result for the Commonwealth for most purposes.

By taking the mean of a large number of returns, price-indexes have been ascertained for **'food and groceries' and for 'food, groceries** and house rent' taken together. The results, when the year 1911 is taken as a basic year and the price-index for it is made 1000, are, for the capital cities of Australia, as shown in the foregoing table. The 'weighted averages' are the price-indexes for the capital cities taken together, due allowance being made for their respective populations. The results are given for 1901 and for 1906 to 1922 inclusive.

The figures given show the variations which have taken place in the purchasing power of one pound sterling. Increase or diminution in the indexes denotes the corresponding increase or diminution in the price of commodities. Thus, given price-indexes, we may readily compare the cost of commodities in different parts of a territory.

Instead of using price-indexes it is often convenient to put such results in a more popular form, stating the amount of money required to purchase what would have cost on the average 20s. in the basic year. In the table given lower in this column the results for Australia and New Zealand are shown in comparison in the manner indicated. They represent the weighted means of the capital cities of the commonwealth of Australia and the four chief towns of the dominion of New Zealand. The table indicates that in 1922 money had only about half the purchasing power that it had during the first decade of the present century. This depression of the value of the money-unit in relation to commodities generally is a world-wide phenomenon.

The cost of living may be investigated from another standpoint, that of food-value. When supplies are abundant, custom or preference

* The year 1911 is taken as the basic year.

will probably always decide as to the choice of particular foods, but when dearness and scarcity prevail it may be necessary to modify the regimen to agree with available supplies. Hence the consideration of the values of commodities as foods (food-values) may often become of the first order of importance. For general purposes such values are appropriately based upon the protein, fat, and carbo-hydrate contents of the various food commodities and their energy-values, the last being measured by the kilogram-calorie, viz. the quantity of heat necessary to raise one kilogram of water 1° centigrade, at its temperature of maximum density (3.97° C.). The regimen used in the computation of price-indexes by the Commonwealth statistician is given in the table hereunder; the quantities of the various commodities are for an average family of five persons, equalling 3.65 man-units. These quantities and their calorific values are as follow:—

AUSTRALIAN PRICE-INDEX FOOD REGIMEN: 1 WEEK.

Commodity.	lb.	Calories.
Bread	21·1	24,813
Flour	6·7	11,062
Oatmeal	0·8	1,487
Rice	1·1	1,794
Sago	0·2	326
Potatoes*	20·2	6,917
Sugar	10·4	18,949
Jam	1·6	1,512
Raisins and Currants	0·6	872
Milk	16·9	5,493
Butter	2·1	7,560
Cheese	0·3	533
Onions	1·5	174
Eggs	0·6	374
Bacon, &c.	1·0	2,708
Beef	8·7	10,614
Mutton	7·5	9,803
Pork	0·8	1,500

* 20 per cent. is allowed for waste.

This gives a total of 106,391 calories per week for 3.65 man-units, which is equivalent to 4164 calories per man-unit per diem; made up from 107 grammes of protein, 136 grammes of fat, and 584 grammes of carbo-hydrates, the protein and carbo-hydrates being taken as yielding 4.1 calories and the fat 9.3 calories per gramme.

The food-values of the English board of trade regimen are less liberal:—

ENGLISH PRICE-INDEX FOOD REGIMEN: 1 WEEK.

Commodity.	lb.	Calories.
Bread	22·0	25,872
Flour	10·0	16,510
Potatoes	17·0	6,533
Sugar	5·33	9,712
Milk	12·1	3,933
Butter	2·0	7,200
Cheese	0·75	1,333
Eggs	1·5	936
Bacon	1·5	4,062
Meat	6·5	7,930

The above quantities represent a total of 84,021 calories for 3.65 man-units, or 3288 calories per man-unit per diem. This is made up from 90 grammes of protein, 94 grammes of fat, and 499 grammes of carbo-hydrates, calculated as above. The normal requirement of a man (normal man-unit), according to the board of trade report, is 3400 calories, made up from 100 grammes each of protein and fat and 500 grammes of carbo-hydrates; this, according to Atwater's standard, is needed by a man occupied at moderately active muscular work. For very active work the calories range from 3835 to 6745, for ordinary work from 3060 to 3480, for light work from 2110 to 2970, for

professional and business men from 2190 to 3285, for persons taking little or no exercise, destitute persons, etc. from 1725 to 2400 calories. It must be borne in mind, however, that the value of food does not depend wholly upon its protein, fat and carbo-hydrate constituents. It appears to be established that it must contain vitamines; if these are absent, a diseased condition, and even death, may supervene. Moreover, researches in Switzerland have shown that where the reaction of a food upon the intestinal tract affects the length of time during which it is subject to digestive processes, the question of residual waste may greatly modify deductions based on mere protein, fat, and carbo-hydrate contents.

It has already been pointed out that the Australian is more liberal than the British board of trade price-index food-regimen, and gives a larger food-value. They could be made identical in calorie-values by a mere increase of the British or diminution of the Australian quantities. Such an increase or diminution would, of course, affect the absolute cost of living, but would not affect in any way the estimation of the purchasing power of £1. It is the relation among one another of the mass units, and not their absolute values, that is alone important in estimating changes in the purchasing power of money. Thus the question of the commodity-purchasing value of money is quite independent of the question of the aggregate cost of living, though the ascertainment of the latter can be accomplished by means of the price-indexes, when it has once been fixed by an appropriate investigation based upon householders' budgets, or their equivalent, for a particular date.

Popular misconceptions exist as to the meaning of 'cost of living,' as applied to the determination of what has been called the 'basic wage' (see INDUSTRIAL LAW), and as to what is really meant by variations in the purchasing power of money. The 'basic wage' is assumed to provide for the normal needs 'of the average employee regarded as a human being living in a civilized community.' This wage was first fixed by a judicial decision in 1907, and the price-index numbers of the Commonwealth statistician have since been applied thereto in order to ascertain the wages which at given later dates have the same commodity-purchasing value. Thus price-indexes have been put to direct practical uses.

G.H.K.

Cotton. In 1845 Sturt the explorer brought back from the Barrier Range a plant of the cotton family—named by von Mueller *Gossypium Sturti*, and usually known as Sturt's desert rose—which, however, has no lint, but only a slight 'fuzz' on the seed-coat. The fact that a lint-bearing *Gossypium* is indigenous to Australia was not suspected until in 1817 John Dunmore Lang (q.v.) drew attention to the occurrence of such plants on islands off the north-eastern coast, and suggested that they might also occur on the mainland. But it was not until 1904 that the curator of the botanic garden at Port Darwin was able to report the discovery of a true lint-bearing cotton-plant, indigenous to the Wildman River district of the Northern Territory.

Attempts to introduce the cotton-plant of commerce date from the first white settlement. Phillip brought cotton-seed with him from Rio, and King grew plants from it at Norfolk Island, but, being quite ignorant of the methods of treatment, could make no use of the cotton when grown. When in England in 1799 he arranged for the supply of more seed and of a portable gin to treat the product; seed was obtained from the Bahamas and from the Isle of Bourbon, but in 1802 King had to report that climatic conditions near Sydney were unfavourable, and that a settlement should be made farther north, where both cotton and indigo could be grown, with maize as a side-line. The colonial office, however, felt that it had enough irons in the fire without experimenting in cotton. In 1807 Edward Luttrell, a free settler of 1804 whom King made assistant surgeon in the colony and Bligh surgeon of the *Porpoise*, reported to the colonial office (apparently in total ignorance of King's experiments) that the New South Wales climate was favourable to cotton-growing, and that 'it would be meritorious in any individual to send out both seeds and plants'; as, however, Luttrell also reported that there was not a good fleece in the country, and that the prospects of a trade in wool were hopeless, his evidence was worth little and was disregarded. Nothing more was heard of cotton-growing until Governor Darling—who had apparently been experimenting for himself—on 24 March 1825 forwarded to London a sample of Sydney-grown cotton 'which I flatter myself in point of either colour or staple is not to be exceeded. It is real Georgian.' This sample excited mild interest in London, since two men with West Indian experience promptly applied for leave to cultivate tropical products, including cotton, in the north of New South Wales: one of them, indeed, came out, procured a large supply of seed of the perennial (vine) sort, and in 1828 commenced operations, but the experiment was ended by his untimely death. Meanwhile a small experimental plot had been started by Robert Dawson, manager of the Australian Agricultural Company; he was suspended from duty in April 1828 and his plot disappeared with him. At the time both the Company and the settlers at large were mainly interested in developing the pastoral industry; all available labour was thus absorbed, and for the next 10 or 12 years the only cotton-growing done in Australia was in botanical gardens. During the forties, however, John Vaughan Thompson, inspector-general of government hospitals in New South Wales, raised good cotton at Moreton Bay, though he failed to make the industry profitable; his partial success stimulated the imagination of J. D. Lang, who was visiting the northern districts to investigate the possibilities of closer settlement there for his Presbyterian immigrants. Much impressed by specimens of cotton from Thompson's farm, and influenced by a few enthusiasts, he convinced himself that perennial cotton could be raised with commercial success by family labour in the Moreton Bay district. Cotton, therefore, was to be his instrument of colonization; he proceeded to London, published a little book on *Cooksland, the Future Cotton-field of Great Britain*, but received no support from the colonial office or from the cotton manufacturers of Lancashire. Undiscouraged, he brought about 600 'virtuous Presbyterians . . . to form the nucleus of a cotton-growing population for Great Britain in Australia and eventually, as I hoped, to give the death blow to slavery in America.' Unfortunately, the colonial government refused to grant land to his immigrants and only a few were able to take up cotton culture, notably Dr. Hobbs, one of the surgeons sent out in charge. In 1851 Lang returned to England, taking with him samples of cotton raised at various places

between Brisbane and the Hunter River, the value of which Manchester experts estimated at from 6d. to 2s. 6d. per lb. The first shipment of cotton in bulk reached Liverpool in February 1854. Throughout the fifties crops of Sea Island cotton were raised sporadically in the northern districts (only one attempt being made to cultivate the coarser varieties) but many circumstances militated against the commercial success of the ventures. There was no local market; transport costs were high; other crops were believed to be more profitable; suitable land was inaccessible to small farmers; labour was both scarce and expensive, and skilled labour—especially for picking—practically unobtainable; seed was badly selected, and different varieties were grown in the one field and mixed in the same bale; and there was an entire lack of suitable ginning machinery, the saw-gin which was introduced having destroyed the fibres of the more valuable cottons. However, the despatch of samples from time to time prevented British cotton manufacturers from forgetting that northern New South Wales was suitable for cotton-growing; and when the political situation in the United States threatened the loss of their customary cotton supplies their interest became more active. During 1859 the secretary of the Manchester Cotton Supply Association wrote to the governor of New South Wales, offering to find a market for all Australian cotton consigned to him. The colonial government thereupon offered prizes for the best specimens grown in the northern districts, and placed orders in London for supplies of seed. Soon after Queensland was proclaimed a separate colony the crown lands alienation act of 1860 provided for the issue of land orders, to the extent of £10 during the next three years and of £5 in the following two years, as a premium for every bale of good cleaned Sea Island cotton that was exported to England. Meanwhile the Manchester association had forwarded cotton-gins, three or four of Dunlop's manufacture being installed in Brisbane by a firm that was prepared to clean and ship cotton on growers' account; and a joint-stock company was formed at Maryborough in Queensland for cotton cultivation, though it was generally believed that, unless coloured labour could be secured, cotton would be more profitably grown as a subsidiary crop by small farmers than on the plantation system. When the American civil war broke out in 1861, and the Manchester mills were starved of their supplies, the agitation for the introduction of coloured labour into Queensland to meet the sudden demand for raw cotton increased. Efforts to secure Indian coolies being unsuccessful, Robert Towns (q.v.) in 1863 imported 67 Kanaka labourers to his plantation, and further importations were made during the following years (see IMMIGRATION RESTRICTION).

Stimulated by the high price of cotton on the British market, experiments in cotton-growing were made as far south as Goulburn in New South Wales (i.e. nearly 35° S. lat.), but without much success. During the period 1862-71 26,000,000 lb. of cotton were exported from Australia, the cultivated area increasing from 320 acres in 1862 to 10,974 in 1870 and 14,500 in 1871: then Queensland cultivators began to feel again the competition of the United States, and production dwindled until in 1888 only 37 acres were planted. The Queensland legislature tried to revive the industry by offering a bonus of £5000 to the first person or company who manufactured cotton goods to the value of that sum from fibre grown in the colony. The Ipswich Cotton Company thereupon established a factory and produced the goods, cotton cultivation in the West Moreton district being greatly stimulated by its operations, but in 1897 the firm was obliged to close down owing to financial difficulties. From these early attempts to establish the industry much valuable information as to the suitability of soil and climate for the different varieties of seed was obtained, and experiments were continued not only in Queensland—where in 1901 Dr. Thomatis obtained the hybrid perennial 'Caravonica'—but also in the Northern Territory and Western Australia. In 1904 the curator of the botanic garden at Port Darwin reported that, besides the native cotton found at the Wildman River, cotton-plants of cultivated varieties were known from other parts of the Territory. Cotton had also been grown successfully in experimental plots in Western Australia since the eighties. He pointed out that northern Australia had this great advantage over the American cotton belt, that the crop ripened in the dry season, thus obviating damage from rain and damp and much lessening the strain of picking.

The drought of 1902 induced the Queensland department of agriculture to encourage cotton cultivation, not only for the lint but also as a fodder-crop for emergencies. In 1903 a commission was appointed to ascertain whether cotton could be grown on a commercial scale by white labour; it reported that a profit could be made by farmers who cultivated it in easily worked areas of from 5 to 10 acres, but that large plantations were unsuited to Australian conditions. Moreover, it was unlikely that farmers would commence cultivation unless a minimum price was guaranteed them for several years. Federal enquiries about the possibility of cotton-growing in the Northern Territory made it evident that before anything was done there on a large scale an experimental station should be established at Port Darwin from which selected seed might be distributed to volunteer growers. The British Cotton-growing Association, formed in 1902, was not impressed by the possibilities of growing cotton with white labour, and decided to undertake no Australian adventures, though, if the State governments would prepare definite schemes, the association would supply seed and machinery. Enthusiasm thereupon lapsed; in 1907 the Commonwealth government offered a bounty of 10 per cent of the market value of cotton grown and ginned in Australia, but with very little result, only £420 being paid as bounty in seven years. The subject was reopened during the sittings of the Dominions royal commission in 1913. The British Cotton-growing Association then offered, providing the Australian governments concerned undertook to make experiments in cotton-growing over a period of three years, to contribute £100 per annum towards the cost, to provide seed for experimental purposes, to undertake shipment, marketing, etc., and to guarantee a minimum net price in Liverpool of 6½d. per lb. This offer did not apply to the product of perennial varieties, or to ratooned cotton (i.e. cotton produced on suckers from a previous year's crop), the association being of the opinion that these were unsuitable for spinning and gave every facility for an increase in cotton pests. The federal government agreed to make provision for the appointment of an expert to be attached to the Queensland department of agriculture to carry on such experiments, but the agreement lapsed. During the war the area under cultivation

in Queensland increased slightly, the total quantity of raw cotton received at the government ginnery being 9500 lb. in 1914 and 166,000 lb. in 1918. The chief deterrent to more extensive cultivation was the high cost of picking, especially as the pickers were unskilled. The Commonwealth Institute of Science and Research therefore interested itself in the possibility of devising a mechanical picker. A special committee was appointed in 1917 to carry out experiments, but the results were not satisfactory, as it was demonstrated that the use of such a machine would necessarily be limited to tractable varieties of cotton. During 1919, however, there were various indications that the price of labour in the United States and Egypt would considerably advance during the succeeding years. There was also a chance of developing a small but steady market in Australia, since the director of the Commonwealth arsenal was specially interested in the production of sufficient local cotton to supply the requirements of the cordite factory. The Queensland government, which from 1913 onwards had made an advance of 1½d. per lb. on seed cotton (increased to 2d. in 1918) and had ginned it on owners' account, guaranteed growers 5½d. per lb. for seed cotton of good quality up to July 1923: the Commonwealth government joined in this guarantee, and the British association insured it up to £10,000. British promoters were by this time convinced that profits could be made even with white labour, provided that pests were excluded and the best seed of the most suitable varieties used: they therefore organized a British-Australian Cotton-growers' Association, and erected modern ginning-plants at convenient centres, making further provision for the extraction of seed-oil and the manufacture of oil-cake. A spinning factory had already been established independently. The result of this fresh impetus is that the area under cotton in Queensland has increased from 72 acres in 1919 to about 35,000 acres in 1923, and the 1923-4 yield of unginned cotton was over 15 million lb. The guarantee for 1924 was 5d. per lb.; for 1925 it took the form of a series of rates from 5¼d. down to 3½d. according to quality. None of these guarantees held good for ratoon cotton. In spite of the high price of cotton in the world's markets these guarantees involved the Queensland government in serious loss, amounting in the two years 1922-23 to nearly £65,000; the Commonwealth shares part of this loss. In 1925 the Empire Cotton-growing Corporation, a British institution, decided to contribute £3000 a year to the maintenance of experimental plantations in Australia. Such plantations already exist in Queensland at Biloela, about 60 miles south of Rockhampton, and at Monal on the upper Burnett.

When cotton-growing began to revive in Queensland, T. L. Bancroft, a son of Joseph Bancroft (q.v.), undertook a series of experiments in hybridization in the hope of breeding a cotton-plant specially adapted to Queensland conditions. In 1924 he submitted to the Imperial Institute in London hybrids of Durango cotton with Eureka, Egyptian, and Sea Island: the Eureka-Durango sample was by experts there valued at a penny a lb. more than good Australian-grown Durango, and the other two hybrids at a slight advance on 'fully good fair' Sakellaridis. In view of the importance of Farrer's analogous work on wheats, these initial experiments with cotton deserve close attention.

See R. Harding's *Cotton in Australia* (1924) which is, however, undoubtedly optimistic.

Cotton-tree. See HIBISCUS.

Cotton-wood. See BEDFORDIA.

Cotula, a large genus of the family Compositae, consisting chiefly of herbs, dispersed over warm and temperate regions. The floral bracts are few, in two rows; marginal florets rayless; seeds flattened, occasionally winged, without pappus. *C. australis,* a flaccid herb with ferny leaves, is a common weed in our lawns. *C. coronopifolia,* a marsh 'daisy' with bright button-like flowers, has a wide range, chiefly coastal. The seeds when immersed emit a gelatinous mucus, which enables them to stick to the feet or feathers of ducks and other marsh birds, and thus secure distribution. *C. alpina* is a small, creeping, alpine herb.

Cowper, SIR CHARLES (1807-1875), born at Dryford in Lancashire on 26 April 1807, was a son of William Cowper (q.v.), colonial chaplain under Samuel Marsden. The father's profession was followed by a younger brother, WILLIAM MACQUARIE COWPER (1810-1902), who was born in Sydney on 3 July 1810, educated at Oxford (B.A., 1833; M.A., 1835), ordained in 1833, made chaplain to the Australian Agricultural Company at Port Stephens in 1836, principal of Moore College for six months in 1856, and dean and archdeacon of Sydney in 1858. He died on 14 June 1902.

Charles Cowper was brought by his father to Sydney when barely two years old, appointed to the commissariat department while still a lad, and in 1826 made by Darling (probably at the instigation of Archdeacon Scott) secretary to the Clergy and School Lands Corporation (for which see CHURCH OF ENGLAND). When this corporation was dissolved in 1833, and the lands it administered reverted to the crown, Bourke offered the young secretary the post of agent for those lands; but he preferred the freedom of unofficial life and the prospective prosperity of a squatter, took to breeding shorthorns, and occupied runs at and near Corryong on the upper Murray. When the colony in 1843 obtained representative government, he entered politics, contesting Camden unsuccessfully against Roger Therry, and was almost immediately afterwards elected to represent Cumberland; this seat he held until 1850, vacated it to contest Sydney against Lang and Wentworth, was defeated, and in September 1851 was elected for Durham and held that seat until the old legislative council was dissolved in 1856.

During this period he was particularly active in two directions. In 1848-9 he carried through the council vigorous resolutions against the revival of transportation; in 1852 was president of the anti-transportation league (see TRANSPORTATION), and represented it at the famous conference in Hobart—Henry Parkes considered him too 'mild, affable and benignant' for the leadership in that cause. A few years earlier (in 1846-9) he had taken up with great vigour the advocacy of railway construction in the colony, and was first president and manager of the Sydney Tramway and Railway Company

(1849-1853). These activities made him so prominent that he became a member of Wentworth's 1853 committee for formulating the new constitution, and of James Martin's 1855 committee on the powers and duties of the executive under responsible government. When the new constitution was granted, and it became necessary to elect a parliament, Cowper headed the poll for Sydney, coming in a few votes ahead of Henry Parkes. In the assembly he became leader of the 'Liberal' opposition, drove the Donaldson ministry from office in less than three months, held the premiership himself for six weeks, spent another year in opposition, and then formed a ministry (7 September 1857 to 26 October 1859) which in its many internal changes introduced to office James Martin, John Robertson and W. B. Dalley. After a nine-weeks interval (while William Forster tried his hand as premier) he took office again, at first as colonial secretary under John Robertson, then (from 10 January 1861) as premier with Robertson under him; from March to November 1860 he was in the council, but from 7 December was back in the assembly as member for East Sydney, a seat which he held until 23 February 1867. His 1861 ministry lasted until October 1863; in a fourth term of office (3 February 1865 to 21 January 1866) he changed his treasurer twice and had two attorney-generals, two secretaries for lands, and two for public works; in a fifth (13 January to 15 December 1870) he again took over the premiership from John Robertson —during this last appearance in the assembly he was member for Liverpool Plains. Then, leaving politics, he took the agent-generalship, worked hard until illness incapacitated him, and died in London on 20 October 1875.

This mere record of his political positions is some indication of his character. Henry Parkes many years later described him thus:—'He had a familiar acquaintance with the affairs of the colony, quick insight in dealing with surrounding circumstances, and much good humour and tact in dealing with individuals. His political adroitness was such that it secured for him the popular sobriquet of Slippery Charlie.' He was, in fact, the great opportunist of Australian politics: some of his cabinets resembled the series of balls that a dexterous juggler keeps continually in the air. He succeeded, however, in carrying several measures of high importance. In 1858 he was responsible for manhood suffrage, the ballot, and a municipalities act; in 1861 he fathered John Robertson's land act; in 1862 he abolished state aid to religion, and passed the real property (Torrens system) act; in 1865 he imposed the first *ad valorem* duties and took part in a conference with Victoria on border duties (see TARIFFS). His one spectacular failure —and that was only temporary—was his attempt to force the Robertson land bills through the council of 1861. It was a dying council, having been appointed in 1856 for five years only. Still, it felt strong enough to insist on serious amendments in the Robertson bills as sent up from the assembly. Cowper therefore persuaded the then governor, Sir John Young, to consent to the nomination of 21 additional members. But, when the new nominees attended a meeting of the council to be sworn in, the president (Sir W. W. Burton, q.v.) resigned his position and walked out of the building, followed by most of his fellow-councillors. Before another meeting of the council could be summoned, the five-year term ended, and the bills had to be held over until a new council was nominated.

When Cowper retired from active politics, his services to the colony were recognized by the presentation to his wife of the Wivenhoe estate, which had been purchased with public subscriptions for the purpose. Outside active politics he was mainly interested in education. In 1854 a committee of his forming recommended the incorporation of the Sydney grammar school; he also strongly supported the establishment of residential colleges affiliated to the university of Sydney. (K.C.M.G., 1871.)

Cowper, WILLIAM (1780-1858), born on 28 December 1780 at Whittington in Lancashire, after earning his living as tutor in a clergyman's family at Northallerton in Yorkshire and as clerk in the depot of the royal engineers at Hull, resigned this position rather than work on Sunday, and set himself to study for holy orders. In 1807 he was ordained deacon and made curate of Rawdon in Yorkshire; early in 1808 he met Samuel Marsden, then on the look-out for chaplains to serve in New South Wales. Marsden approved of him highly, the colonial office confirmed the choice, and at the end of the year Cowper was ordained priest and formally appointed assistant chaplain for the colony. On 18 August 1809 he reached Sydney in the *Indispensable*, and on the 19th took charge of St. Philip's church on Church Hill, where he remained for 49 years. The existing church was built under his direction. In 1814 he was solemnly rebuked by Macquarie for using an unauthorized version of the Psalms at morning service. His duties included regular visits to the hospital and gaol, and he attended at least 300 criminals on the scaffold. In 1818 Marsden reported that Cowper was very infirm and unable to discharge the duties of his office; in 1829 Darling described him as nearly worn out by his exertions and by the climate; but it was not till 1842 that he was able to obtain leave of absence and proceed to England. In 1843 the archbishop of Canterbury gave him the 'Lambeth' degree of D.D. Returning to Sydney in that year, he resumed work at St. Philip's, but in 1848 was made by Bishop Broughton archdeacon of Cumberland and Camden: in 1852 he acted as bishop's commissary during Broughton's absence in England. He died on 6 July 1858.

William Cowper had great force of character, and his fearlessness gave him much influence among the rougher elements of the community, as did his steadfast refusal to become a magistrate—a post which he considered incompatible with his calling. He heartily aided Macquarie in his endeavours to help the aborigines, and as an advocate of higher education actively promoted the establishment of the King's School at Parramatta and St. Paul's College within the university. His sons Charles and William are dealt with under COWPER, SIR CHARLES.

Cowries. See MOLLUSCA.

Cox, WILLIAM (1764-1837), born at Wimborne Minster in Dorsetshire on 19 December 1764 and educated at the local grammar school, joined the Wilts militia on the outbreak of war with France in 1793 and in 1795 obtained a commission in the army (ensign, 1795; lieutenant, 1797; captain, 1808). In 1797 he joined the New South Wales Corps as lieutenant, being appointed paymaster in 1798 before he sailed for Australia. The vessel in which he came out (the *Minerva*) also carried a number of the 'Irish Exiles,' among them Joseph Holt

(q.v.), and Cox found him a good adviser on farming matters. When, therefore, soon after his arrival (on 11 January 1800) he began to buy land at Brush Farm and Canterbury, he obtained the services of Holt as overseer, and through him procured information of a proposed rebellion among the Irish convicts. In 1801 he was the owner of 1380 acres, all of which he had purchased from private vendors; but these purchases so strained his credit that in 1803—when he owned, besides the land, about 100 cattle, 2000 sheep and '£4000 worth of trading property'—he was made bankrupt by the army agents in England and suspended from his military duties, his estates being handed over to trustees. In 1807 he was ordered to England to answer charges connected with this bankruptcy, but cleared himself of all suspicion, was restored to his regiment and given his captaincy. He returned to New South Wales to settle down as a farmer at Clarendon near Windsor and resign his commission. He kept clear of the Bligh mutiny, and was made magistrate at Windsor by Macquarie—for which appointment the settlers there publicly thanked the governor on 1 December 1810. About this time Cox's sons investigated the country between Windsor and Camden, where Thomas Jamison (ex-surgeon-general) had already a 1000-acre block that was afterwards Regentville; William Cox and his family took up 4000 acres south of him at Mulgoa, Gregory Blaxland settled just below them at Wallacia, and in no long time the John Blaxlands, father and son, acquired land eastwards at Luddenham. Cox had already done a good deal of road-making in the county of Cumberland when, after Blaxland's crossing of the Blue Mountains and Evans's extension of the new discoveries to the Bathurst plains (for both which see EXPLORATION BY LAND), Macquarie in July 1814 made him superintendent of the works for a new road over the mountains. Within six months he made 101 miles, and on 21 January 1815 reported to Macquarie that the road was completed. In April-May the governor traversed it with a party including his wife, Sir John Jamison, William Cox, Lewin the artist, Oxley, Evans, and Redfern, and signified his approval in the usual fashion by naming the pass down Mount York and the river just beyond it after the maker of the road. His general order of 10 June highly eulogized Cox, and his despatch to Bathurst of 24 June suggested that the road-maker should be made commandant of the Bathurst settlement until it was well enough established to leave it to the ordinary methods of local administration.

This appointment was never made, nor was a payment of £300 which Macquarie recommended at the same time. In May 1817 he was still entreating the colonial office to give him some answer about these recommendations. But Cox obtained the first grant of land made to a free settler in the new territory—a 2000-acre block, now known as Hereford, immediately across the river from the government township; on this in 1820 Bigge found 5000 sheep pastured, farm buildings erected, and experiments with artificial grasses in progress. Cox also busied himself with minor explorations, examining the Lachlan in advance of Oxley's journey of 1817 and transporting to the river-banks all stores, stock, and boats required for the expedition. His home, however, was still at Clarendon, and he was magistrate at Windsor for many years. Brisbane in 1824 recommended him as an original member of the proposed legislative council, but nothing came of this: only three of Brisbane's ten nominees were appointed. He died at Windsor on 15 March 1837. His family included some of the most enterprising pioneers of Australian settlement. His eldest son William had estates at Windsor and Muswellbrook; his second, James, settled at Clarendon on the Esk in Tasmania; a third was killed in Fiji; Henry, George Henry, and Edward pioneered Mulgoa on the Nepean, George and Henry afterwards settling near Mudgee, while Edward stayed at Mulgoa. George's brother-in-law, Archibald Bell, was the discoverer of the stock-route from Windsor to Bathurst and Mudgee (still known as Bell's line) which runs over the Kurrajong to Mount Tomah and behind Mount King George to the railway line at Bell and thence direct to Lithgow.

The Penrith-Bathurst road, which was Cox's most remarkable achievement, deserves description. His instructions were to commence at the ford of the Nepean and follow the track laid down by Evans (with such deviations as he might prefer) to 'a centrical part of Bathurst Plains.' The roadway was to be 12 feet wide, the clearing through timber 20 feet wide; his working party of 30, 20 of whom were convict labourers, was guarded by eight soldiers. On 18 July 1814 he made the first cutting down to the Nepean ford; on 14 January 1815 he was forming the roadway at Bathurst. The chief difficulty was encountered at Mount York, where the grades were so steep that he proposed to make only 'such a road as a cart can go down empty or with a very light load, without possibility of its being able to return with any sort of load whatever.' The actual gradient was 1 in 4, and for many years all carts had to be brought up the hill empty. Easier deviations were made in 1827 and 1829, and in 1832 an entirely new road down Mount Victoria was constructed by T. L. Mitchell and opened by Bourke. Cox's road, descending into Hartley Vale and doubling southwards to the Cox River behind Hartley, then ran SW. from Mount Blaxland to the head-waters of Jock's and Antonio's Creeks, crossed the Fish River near Hobby's Creek, and reached Bathurst by way of O'Connell Plains and the Campbell River crossing at White Rock.

Crabs, animals (mostly marine) belonging to two sub-orders—Brachyura and Anomura—of the order Decapoda and class Crustacea. The Brachyura (true crabs) are discussed here; the Anomura are dealt with under HERMIT CRABS, which are the principal Australian representatives of that sub-order.

The Brachyura are distinguished from other Decapoda by having the abdomen short and bent up under the body, where it lies closely adpressed in a shallow concavity. The front (anterior) part of the carapace possesses a process which passes downwards to form a septum between the inner pair of feelers (antennules), and joins below with a plate (epistome) above the mouth-parts. The sixth pair of abdominal appendages (uropods) is generally absent, rarely present as rudiments. The outer pair of jaws or mouth-parts (third pair of maxillipedes) are generally broad and flattened, forming 'folding doors' which cover the other mouth-parts. Five tribes are included in this large sub-order, all represented by numerous types on every section of the Australian coast, while a few specialized forms are found in certain inland fresh waters.

The tribe Dromiacea (sponge-crabs, etc.) is the most primitive of existing Brachyura. This is indicated by the retention of a vestigial pair of limbs on the first abdominal segment (somite) of the female, and often on the sixth abdominal segment in both sexes. Further, the gills are in most cases more numerous than in the other Brachyura. The last pair, or the last two pairs, of legs are dorsal in position, with hooked or prehensile claws; the mouth-frame is square. In this tribe are three existing families, two of which (Dromiidae and Homolidae) include numerous forms common in Australian waters.

In their young stages the typical sponge-crabs (family Dromiidae) resemble lobsters in many points of structure. Their bodies are thick and furnished beneath with false swimming-legs, and end in a fan-like expanded fin, adapted for swimming. But in the adult state, when the abdomen is reduced and bent under the body, the crabs become more or less sedentary in habit. The last pair (or the last two pairs) of legs are short and carried up over the back, where they serve to hold a mass of living sponge, half a bivalve-shell, or some other marine growth, which forms a cloak to protect and conceal the bearer; the mass is firmly secured by the nippers on the hinder legs, which are perfectly developed, sharp and strong, and are formed by the opposition of the terminal joints of each leg to prolongations of the last joints but one, as is usual in the normal claws of the hand. At the sides of the abdomen, wedged in between the tail-pieces (telson) and the last abdominal segment, is a pair of small plates which are the last vestiges of the hinder abdominal appendages (uropods) present in both Macrura and Anomura. These are lacking, even as rudimentary structures, in all other members of the Brachyura.

Sponge-crabs inhabit shallow and moderately deep water on sandy and muddy bottoms. Their habit of carrying sponges and other marine growths on their backs protects them from observation by their enemies, while the animals which provide the cloak obtain a better supply of water and the food contained in it than they would if they were stationary, and are apt to grow at a rate which, if uncontrolled, would make them envelop their bearer. The crab, therefore, prunes off portions that grow where they are not required. During the process of moulting (ecdysis) common to all crustaceans, the crabs have to shed attached growths along with their shells, but probably select choice cuttings from their old coverings and re-establish them on the new shells.

The Bristled Sponge-crab (*Cryptodromia octodentata*), widely distributed in shallow waters off a great length of the eastern, southern, and western coast-lines, is characterized by the possession of strong bristly hairs that completely cover the body. When captured, it is often free from any protective covering, and the carapace is bare save for an accumulation of silt, etc., intermingled with the hairs. The Shaggy Sponge-crab (*Dromidiopsis excavata*), is commoner than the last-named species, but has a similar range and distribution. Great quantities have been trawled off Montague Island and Eden on the New South Wales coast, and off many parts of the Victorian coast farther southward. Though it commonly utilizes a sponge for its covering, this crab may adopt a compound animal colony of ascidians (sea-squirts), which is fleshy and jelly-like in appearance. Both the above crabs are drab brown in colour, and, like their allies, appear quite lifeless when taken from their homes on the sea-floor. It is possible that this is a result of conscious action, by which

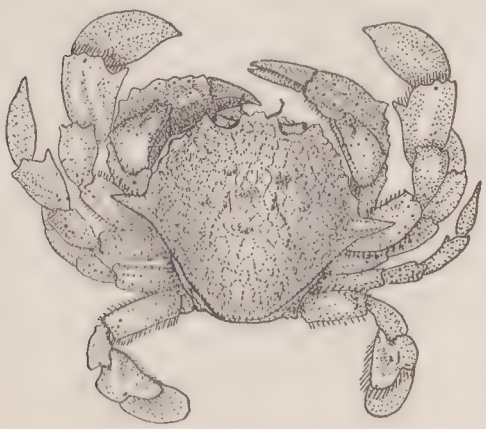
Bristled Sponge-crab, with half of body denuded. (about ⅓ natural size).

the crabs hope to evade detection. Many other species of the family occur in Australian waters, the tropical regions harbouring a great variety of small forms.

To the aberrant family Homolidae belongs the Slender Crab (*Latreillia australiensis*), which occurs commonly in deep water off the coasts of New South Wales and eastern and southern Victoria. In the triangular shape of the carapace, and the length and slenderness of the legs, as well as in its habit of living among the branches of seaweed and other marine growths, this crab superficially resembles some of the spider-crabs of the tribe Oxyrhyncha. The slender crab is pinkish in colour, mottled with spots of red. The few members of the Homolidae do not disguise themselves with coverings of other animals, as do the Dromiidae.

Members of the tribe Oxystomata may be recognized by the triangular shape of the mouth-frame, which is narrowed in front and extends forward between the eyes. They have their gill-openings placed very near the front of the carapace—an arrangement correlative with their general characteristic habit of concealing themselves in the sand, where they lie buried with only the eyes exposed. Four families make up the tribe, all of which include representatives common to our fauna. Typical members of the family Calappidae are not a little remarkable in appearance. This is partly due to the form of the carapace, which is much narrowed in front but widened behind, with shield-like expansions over the bases of the legs. More singular, however, is the development of the nipper-limbs (chelipeds), which have a very flat, crested hand of great size, the whole limb being so arranged that the pair can be concealed beneath the body—to which, in that position, they supply a sort of operculum or incomplete ventral carapace. These box-crabs, as they are sometimes called, are confined mostly to the tropical and subtropical zones, rarely occurring farther southward. The commonest species is *Calappa hepatica*, remarkable for the extraordinary speed with which it burrows; it lives in shallow water upon sand-flats, where it lies buried in the sand, and can only be detected by the presence of its eyes protruding from the surface. If approached, it will scurry away with extreme rapidity, and after running a short distance, will turn and face its pursuer, at the same time burrowing backwards with lightning speed into the soft sand. In the dawn-crabs (*Matuta*) the adaptation for swimming attains its highest development. All four pairs

of legs are formed for swimming, and have broad, flattened terminal joints, which are used as paddles as well as for burrowing; moreover, in the last pair the oval terminal joint is supplemented by a very broad expansion of the preceding joint. Strangely enough, none of the limbs are fringed with hairs, as is usual among swimming crabs; such a fringe would interfere seriously with the digging powers of the sharp points and edges of the terminal joints. As it is, they disappear under the sand in a moment,



Dawn-crab (*Matuta picta*)
(½ natural size).

and before the troubled water has cleared over their departing forms all traces of them are smoothed and lost. Their movements beneath the sand may sometimes be perceived under the feet of a person walking along the shore. Several species occur along the tropical and temperate zones of our coast-line, and commonly frequent open and shallow ocean beaches.

The family Leucosiidae is represented in Australian waters by several genera, commonly called pebble-crabs; they are remarkable for the extraordinary thickness of their carapaces, which are often highly polished in life, and beautifully marked. The pincer-bearing limbs are sometimes ridiculously elongated, and give the crabs a grotesque appearance. Most of the more striking forms are only secured by dredging, but in tropical regions pebble-crabs commonly inhabit the shallow waters of the reefs. *Ebalia crassipes* is common along the south-eastern coast-line, while tropical and subtropical districts are inhabited by many representatives of the typical genus *Leucosides*, among them the handsome *Leucosides longifrons*.

In the frog-crabs (Raninidae) some of the abdominal segments (somites) are visible from above—as is the case with the other family (Dorippidae) of the same tribe, and the last pair of legs is elevated on the dorsal surface. The legs, however, are flattened and paddle-like, and appear to be used for swimming and digging. The family includes about nine genera, which occur chiefly in tropical regions, and descend to depths not exceeding 300 fathoms. A species called *Ranina ranina*, a typical Australian member of the family, occasionally wanders as far south as Port Jackson. In general appearance it is one of the most striking and aberrant of the Brachyura. Its carapace, which has been compared to an inverted triangle, is very broad anteriorly, but the sides slope very gradually to the rounded hinder margin. Another smaller form is *Lyreidus tridentatus*, which occurs off the Queensland and New South Wales coasts, and has often been taken by trawlers in a depth of about 75 fathoms. Its range extends from Japan southwards to the New South Wales coast.

In the tribe Oxyrhyncha the carapace is usually triangular in shape, narrowed in front, and produced to form an anterior projection or rostrum. As a rule, the legs are long and slender. This tribe of sharp-snouted crabs includes a great number of species that are generally sluggish and inactive; many mask themselves with seaweed, sponges, etc., others have the shape of their carapace modified to resemble their surroundings.

The members of the family Maiidae, commonly known as spider-crabs, are the typical Australian representatives of the tribe. One of the commonest Australian species is *Hyastenus diacanthus*, which has a wide range along our eastern shores, occurring very plentifully in bays and river estuaries, where it is fond of inhabiting the water over muddy bottoms. This crab is nearly always completely hidden under a luxuriant growth of marine life, and from its habit of attaching living sponges to its carapace, is commonly known as 'sponge-crab,' though it is far removed in both appearance and affinities from the true sponge-crabs (Dromiidae). On close examination it will be found that the mass of living growths is attached to the crab's back by means of numerous hooked hairs, which are embedded in the substance of the hard carapace. If an example of the species could be secured immediately after it had cast its shell, it would be found covered with a thick coat of these hairs; but their tips, instead of being curled over, would be almost straight. Soon, however, they would begin to curl and twine like the tendrils of a vine round the stems of marine growths placed there by the crab, and in so doing would harden. The seaweed-crabs of the genus *Naxia* are also very common, but prefer clearer water, and are often seen at low tide in shallows on the rocky reefs of the open coast along most of the eastern and southern shores of the continent. They always live in association with seaweeds, and cover themselves with a thick growth, which makes them hard to detect. The Harlequin-crab (*Camposcia retusa*), from our tropical coasts, is possessed of a very dense growth of hairs, which it utilizes for the attachment of a marvellously varied assortment of marine growths; these, when living, cover it with a coat of many colours, and effectively hide it from the many enemies that abound among the coral reefs where the crab makes its home.

Crabs belonging to the tribe Cyclometopa have the carapace as a rule broader than long, with the antero-lateral borders convergent. The front is not produced into a rostrum. With the exception of a single family (Potamonidae, which includes the river-crabs), all the very numerous members of this tribe inhabit the sea, and many are familiar littoral forms. It includes several families which frequent our shores, but only three of the best-known are mentioned here.

In the large and very varied family Xanthidae the carapace is usually transversely oval, and its surface is often lobulated. The species of this family are very abundant along the littoral, especially in the tropics. In life many are vividly coloured, as is usual among tropical animals. The Giant Tasmanian Crab (*Pseudocarcinus gigas*), on account of its huge dimensions, is the most striking member; it may measure as much

as 13 inches across the carapace, and turn the scale at 20 pounds, while the hand may be 17 inches long from its base to the end of the large nippers which it supports. It is fairly common in depths of 50 to 80 fathoms off the eastern coast of Tasmania, and in the Great Australian Bight; occasionally it wanders as far northward as the southern section of the New South Wales coast, where trawlers have obtained a few examples. When hauled on board ship these crabs are almost paralysed, owing to the sudden reduction of the great pressure under which they are accustomed to live, and may be handled with impunity. Under natural conditions, however, they must be formidable enemies, armed as they are with huge nippers sufficiently powerful to crush a man's wrist. In life they are beautifully marked with blotches of rich red on a porcelain-white ground. As an article of diet the flesh of the giant Tasmanian crab has been highly esteemed by the few persons fortunate enough to try its quality. A. R. McCulloch states that many specimens trawled off Babel Islands in Bass Strait by the Commonwealth trawler *Endeavour* in the early part of 1914 were highly esteemed by the crew as delicate articles for the table, their massive limbs supplying an abundance of white flesh.

Swimming-crabs, the typical members of the family Portunidae, may be recognized by the flattened, paddle-like form of their last pair of legs. The Blue Swimming-crab (*Portunus pelagicus*) and the Mangrove-crab (*Scylla serrata*), the largest Australian members of the family, are well known and highly appreciated as food delicacies by residents on the coast. *P. pelagicus*

Giant Tasmanian Crab
(about one-fifth natural size).

occurs throughout the temperate and tropical waters of both the Pacific and the Indian Oceans, and is fond of frequenting shallows in bays and river estuaries, where it is secured in seine nets along with hauls of fish, and is commonly offered for sale in seaboard cities. In colour the species is beautifully mottled with blue. It possesses a sharp elongated tooth on each side of its carapace, which, together with the spines on its nipper-limbs, make it an awkward beast to handle when alive. The mangrove-crab is the larger of the two, and has a pair of heavy nippers, the fingers of which are jet-black; the rest of the shell is smooth, and earth-brown in colour. The species ranges from Sydney to Japan. It is very plentiful in northern Queensland waters, where it infests the mangrove swamps; the aborigines with the aid of canoes and spears procure great quantities in a short space of time. In Sydney shops it is not infrequently offered for sale along with the commoner blue swimming-crab. A smaller relative is the Periscope-crab (*Podophthalmus vigil*), which is worthy of mention on account of the great length of its eye-stalks—a feature quite unusual among the Cyclometopa. This species congregates on muddy flats on the northern Queensland coast, where it moves about more or less buried in the ooze, often with only its eyes projecting above the surface, on the watch for impending danger.

The river-crabs (family Potamonidae) are represented in Australia by some species of the genus *Geotelphusa*. These are freshwater forms; some live entirely in the water, others lead a more or less amphibious existence, and burrow freely in damp earth on the banks of streams and waterholes. They are widely distributed throughout most of the freshwater systems of northern Queensland; one species (*G. leichhardti*) ranges as far south as western New South Wales (where it is somewhat rare) and as far west as the Northern Territory.

In the tribe Catometopa the carapace is typically more or less quadrate, with the front

strongly bent downwards. Some representatives live on the land or in fresh water, but the greater number occur between tide-marks on the shore, and in the deeper waters of the sea. Only a few representatives of the true land-crabs have been recorded from Australia. The two best-known families of this tribe represented in our fauna are the Grapsidae and the Ocypodidae, notes on which may be supplemented by a general mention of the interesting members of the Pinnotheridae. Crabs of the family Grapsidae are the typical members of the tribe Catometopa. They have the carapace nearly quadrilateral in shape, with the front very broad, and the orbits situated near the antero-lateral corners. Many species are estuarine or fluviatile in habitat, and almost always littoral or shallow-water forms, with a rare exception in deep water. The commonest shore crab on the Australian coast is the Rock Crab (*Leptograpsus variegatus*). Examples of this species are to be seen scampering about everywhere along the shore-line of the southern half of the continent, rapidly seeking a safe hiding-place as an onlooker approaches. They are very audacious and cunning, and jump from rock to rock in a manner approached by but very few other crabs. Writing of the voracity of an allied species occurring on St. Paul's Rocks in the Atlantic, Charles Darwin noted that it was amusing to watch how quickly these large and active crabs, which inhabited the crevices of the rocks, stole the fish from the nests of the terns so soon as the parent birds were scared away by his party. Even the young birds were dragged from the nests and devoured. This habit, however, has not yet been recorded of the Australian species. The rock crab can live partly out of water, and is often under damp rock ledges above high-water mark, while it frequents both salt and brackish rock-pools. In crevices it moves around freely in search of food, gripping firmly to the barnacle-covered perpendicular walls of its habitat, and defies dislodgment by the force of the waves. Large specimens of the species may measure up to two inches in breadth of carapace.

The genus *Sesarma* includes a very large number of species, confined mostly to the tropical regions. They are strong, active crabs, with more than ordinary powers of defending themselves. A form known as *S. mienerti* is common on the Queensland coast, and exemplifies the strong build of its kind in the power of its claws and the strength of its legs. The latter are provided towards their tips with numerous stout hairs, which are directed downwards so as to offer resistance to the soft mud upon which the crabs live. They spend their time largely out of water, and inhabit mud-flats at the very highest limits of the tide, often venturing into the branches of mangrove trees, where they climb about in search of food. The species of *Sesarma* are remarkable in possessing a very elaborate breathing apparatus which enables them to remain a long time out of water. On each side of the body is a grill-like structure covered with fine hairs and arranged in definite series; the oxygen in the water contained within the gill-chambers when the crab leaves the sea soon becomes exhausted by the ordinary process of breathing, but is replenished when the water is spread in a thin film over this grill arrangement. The same water can therefore be utilized again and again by a crab until evaporation demands the creature's descent to its native element.

In the family Ocypodidae the front is generally narrow, and the eye-stalks are often very long. Most of the species are amphibious shore-crabs, and some have extremely wide ranges. Several species of the typical genus *Ocypode* occur in Australia, and are very common on most sandy shores in the tropical regions. These sand-crabs often congregate in vast numbers, and, as their generic name implies, are very swift of foot. On wind-swept stretches of sandy beach they appear rather to be borne on the wings of the wind than to run. They dig into the sand with their compressed lance-like fingers, and excavate burrows which may be as much as four feet deep; from these they wander far in search of food when the tide is out. While engaged in these hunting excursions the crabs are ever on the watch for possible danger, and every now and then stand high on their legs, raise their stalked eyes, and look carefully round. At the slightest movement they make for the nearest burrow, or, if the danger is too close, press themselves flat on the sand until an attempt is made to seize them, when off they dart. When running they carry their bodies high, doubling and dodging with such speed and cunning that it is a difficult matter to capture them. When the tide comes in, the crabs which have their holes below the high-water line are enclosed in their flooded burrows; so soon as the waves retreat again, they may be seen busily employed in clearing them, dexterously shovelling out the wet sand and heaping it at some little distance off. Species of *Ocypode* are said to feed upon many of the small lower crustaceans which commonly live in the sand, lying in wait and suddenly springing upon them much as a cat catches mice. They also feed upon dead fish and other animals that are cast on the shore by the waves. Though the gills of the sand-crabs are well developed, they do not nearly fill the large gill-chambers, and the creatures soon drown if kept under water. They breathe perfectly on land by means of a thick vascular lining of the gill-chambers, while two special apertures for the intake of air are developed between the bases of the second and third pair of walking legs; their openings are protected by a thick tuft of long,

Swift-crab (*O. ceratophthalma*), (one-third natural size).

peculiarly formed hairs, which act as a filter to prevent the entrance of sand grains and other foreign matter into the gill-chamber, while allowing the free passage of the air. On the inner edge of the larger hand, in most of these crabs, is a row or keyboard of fine teeth, which, when the arm is flexed, can be made to play against a similar ridge near the base. This produces a shrill grating sound, and serves among other uses to warn intruders that the owner of a burrow is already at home. The two commonest Australian species of the genus are *O. ceratophthalma* and *O. cordimana*, which are often found in association on the same stretch of beach.

The calling or fiddler crabs (*Uca*) inhabit the

shores of our warmer seas, and are particularly abundant in muddy estuaries. They are great burrowers, and live in vast numbers between tide-marks in salt-marshes and on mud-banks, which are often riddled with their holes. The adult male has one hand enormously increased in size, the other is quite small; the female has hands of equal size, similar in structure to the male's small hand. When feeding the males use the small claw only for picking up food, the females use either claw indifferently. The great hand of the male is always brilliantly coloured; its principal value seems to lie in its formidable appearance, since it seems to be a considerable hindrance to the crab's movements, and is so unwieldy that its owner can inflict but little harm with it. Males may be seen at the mouth of their burrows with the large hand in constant motion, as though beckoning to attract the attention of a female—hence their name, 'calling' crabs. One species has been observed to burrow by digging up pellets of sandy mud, which are carried under three of the ambulatory legs of one side; the crab climbs up the burrow with its load by means of the remaining legs, looks cautiously round from the mouth to make sure the way is clear, and then runs quickly to a distance of four or five feet before dropping the excavated material. The creature works in this way whenever the tide is out and the weather is suitable, both at night and in the brightest sunshine. The principal Australian species of the genus are *U. dussumieri*, *U. marionis*, *U. tetragonon*, and *U. coarctata*. The last-named is remarkable for its brilliant colouring. The back is glossy black; the huge claw, the under-surface of the body, and all the other limbs, are the most brilliant scarlet vermilion, inclining to crimson.

The famous Army Crab (*Mictyris longicarpus*) is also included in the Ocypodidae. This species is very plentiful on extensive sandy stretches in the bays and estuaries of the eastern coast. When the tide is high nothing is seen of the crabs. Shortly after the tide recedes, however, armies of them rise up as if by magic from the previously barren sand, and, assembling in battalions, march in open order, the separate companies seeming to move in definite directions, as though amenable to strict military discipline. Male individuals often lead the van of these moving battalions, and seemingly fulfil the duties of commanding officers. If followed by an observer, they continue their march at an accelerated pace; if overtaken or pressed hard, they disappear beneath the sand almost as suddenly as they emerged. On the other hand a whole crab-cavalcade may retire before a close pursuer right across a sand-flat, and disappear in the shallow water at its edge. The colour of the army crab's body is usually pale blue or lilac, and the limbs light flesh colour. The structural peculiarities of *Mictyris* distinguish it from all other crab genera, and explain the singular celerity with which its members burrow into the sand. The body is almost globose in shape, but more dilated above; the external maxillipedes (foot-jaws) are wonderfully developed, and protrude from the other mouth-parts in the form of a comparatively huge half-sphere. When burrowing, their narrowed bases are driven foremost, a spiral motion is communicated to the body by the action of the walking-limbs and claws, and the complete organism thus constitutes itself a sort of animated centre-bit.

From remote antiquity certain little crabs of the family Pinnotheridae have been found living within the shells of bivalve molluscs, such as oysters, mussels, and especially the large mussel-like shell *Pinna*. Ancient writers regarded this as a case of association for mutual advantage, believing that the crab warned the *Pinna* of the approach of enemies, or of the entrance of prey between its gaping valves. It is even stated that the *Pinna* and crab were depicted in Egyptian hieroglyphics to symbolize the dependence of a man on his friends. There is no reason to suppose, however, that the molluscs which harbour the *Pinnotheres* and some allied genera benefit in any way by the presence of the crabs. The latter probably feed, as their hosts do, on particles brought in by the current of water entering the mantle-cavity. They are therefore strictly 'commensals,' though it is usual, and perhaps equally correct to speak of them as 'parasites'—the case is, indeed, an example of the difficulty of defining these terms. Pinnotherid crabs show one of the characteristics of parasites in being to some extent degenerate in their structure. The carapace, no longer needed for protection, has become soft and membranous, the large chelipeds are reduced to diminutive proportions, and in the typical genus *Pinnotheres* the eyes and all the antennal, ocular and mouth-parts, so important to a free-living crustacean, are reduced to almost rudimentary structures. The males are usually smaller and less modified than the females, and move about more freely. As in many parasites, also, the eggs produced by the females are very numerous, and the abdomen is very broad and deeply hollowed out for their reception. Two or three crabs may be found in the one mollusc. A member of the typical genus (*P. villosulus*) is found on the northern coast of Australia as a commensal of the pearl oyster. Another species (*Xanthasia murigera*) takes up its abode in several kinds of clam on the reefs in our warmer waters. The 'mutton-fish' univalve (*Haliotis asinina*) harbours *Pinnixa faba*, which may be found on the coast as far south as New South Wales, but is more common farther north.

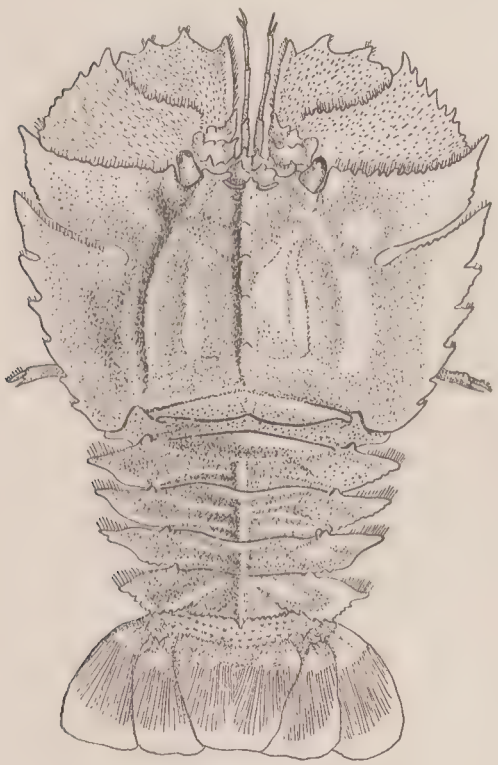
Crayfishes, animals belonging to three tribes of crustaceans—order Decapoda, sub-order Macrura—which include the marine crayfishes (usually known in Australia as 'lobsters,' but only distantly related to the European lobster), the yabbies and freshwater crayfishes, and the prawn-killers. Among the marine crayfishes (tribe Loricata) none of the legs bear nippers (chelae). Specimens of both the families into which this tribe is divided are common along the Australian coast-line. In the family Palinuridae the body is more or less cylindrical; the antennae are long, round, and jointed. The other family (Scyllaridae) is remarkable because the antennae are modified into the form of broad flat plates, which appear as shovel-like attachments protruding from each side of the front part of the head; these are said to be used in burrowing. Among the commoner varieties of the Palinuridae two (often called in the trade 'crawfish') are the mainstay of the crustacean industry of the Commonwealth, and are sold all the year round in the markets of the capital cities under the commercial name 'lobster.' The supply for the Sydney markets is primarily furnished by *Jasus verreauxi* (Spiny Lobster), which is abundantly distributed along the eastern seaboard from its

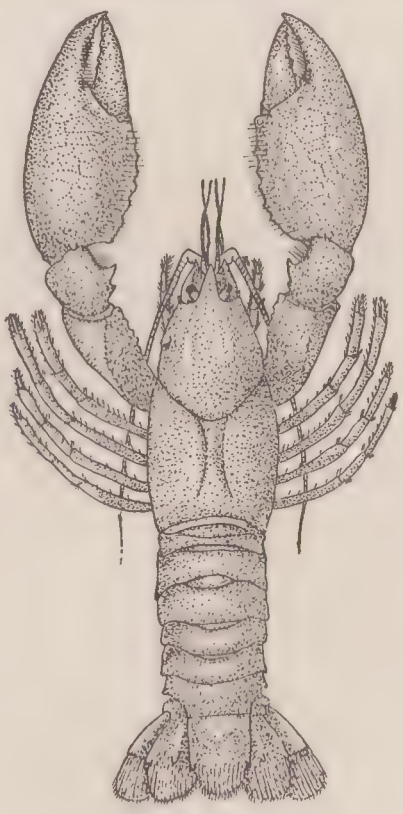
south-eastern extremity up to southern Queensland. Some specimens turn the scales at six pounds or more. The colour during life is a dark foliage-green. The principal catching-centres are Cape Hawke, Port Stephens, Broken Bay, Port Jackson, and the Shoalhaven bight. Shipments vary greatly in quantity, possibly because of the ruthless destruction of breeding females—a matter to which great attention has been given in countries such as the United States of America, where special laws provide for strict supervision in catching, and an unending supply is consequently always within reach of the consumer. The second species, *J. lalandii*, has a much wider distribution, and is more brightly coloured. Its range extends right along the southern half of the Australian coast-line, and it is common in Tasmanian waters. The supply on the eastern coast has been increased during the last few years by the liberation of batches of young from the fish hatchery at Port Hacking, near Sydney. The two commercial species are easily distinguished by the character of the upper plates (terga) of the segments of the abdomen; in *J. verreauxi* these are smooth but for the presence of tiny pits on the surface; in *J. lalandii* they are sculptured.



Prawn-killer.
(about ⅓ natural size).

Far north, on the eastern Queensland coast, some brilliant tropical species of the family occur, but rarely find their way to market. One of these is *Senex ornatus*, remarkable for the possession of colouring which harmonizes with other brightly-tinted organisms peculiar to the coral reefs that this species inhabits. The family Scyllaridae includes the broad-fronted crayfishes. One species, *Scyllarus sculptus*, has the same distribution as the spiny lobster, is found under the same conditions, and is often captured in 'lobster pots' along with the commercial lobsters; it is, however, smaller than these and does not occur in sufficient quantity to be of much commercial value. Confined, as a rule, to the deeper waters is *Ibacus incisus*, remarkable for its greatly depressed form and extraordinary lateral expansion of the carapace and antennae, which are deeply incised to form numerous sharply-pointed teeth. Great numbers of this species are secured by trawlers off the coast of New South Wales, when the ships are working over sandy bottoms. This 'prawn-killer,' as it is called by local fishermen, is of no commercial value, since it has very little flesh. Like *Scyllarus sculptus*, it is red in colour, but of a very much lighter tint.

Among the Nephropsidea are included the freshwater crayfishes, which have the first three pairs of legs pincer-like (chelate), the first pair being very large and formidable. All the Australian representatives are grouped in the family Parastacidae. Several genera and numerous species occur in Australia and Tasmania, and some of the larger ones are often used for food. They are specially remarkable for their variety



Yabbie
(⅓ natural size)

and their great size, the Tasmanian Crayfish (*Astacopsis franklinii*) being the largest crayfish in the world. It inhabits the creeks and rivers of northern Tasmania, where it grows to about two feet six inches in length, and may scale eight or nine pounds; the claws of large specimens are formidable weapons, about the size of a man's hand. It is excellent eating, being less coarse than the spiny lobster, but is difficult to capture and never appears in the market; the only people who eat it, or know anything about it, are a few

permanent residents in the localities where it occurs. In colour this giant is generally a uniform dense chocolate-brown, but it may be nearly black. Next in size is the Murray River Lobster (*Astacopsis serratus*), which commonly attains a length of eighteen inches, and is at times exhibited for sale in the Sydney and Melbourne markets. A remarkable feature of this species is its extraordinary range of colour variation. Specimens caught near Sydney are generally dark green, with blue and red markings; those from the Murray River and its tributaries are lighter in colour, with white hands; smaller specimens from streams of the Great Dividing Range are often quite red, as though they had been boiled. The Yabbie (*Parachaeraps bicarinatus*) is smaller than either of the last-mentioned species, rarely attaining a length of nine inches, but is the most widely distributed Australian member of the family, occurring over the greater part of the continent, and entering even the central desert areas. Chiefly found in the waterholes of the more sluggish streams, it is well known to settlers as an inhabitant of their artificially constructed dams, some of which are so far from permanent watercourses that it is difficult to understand how the crustacean becomes established in them. Like its allies, it excavates burrows in the banks surrounding the water it inhabits; unlike its allies, it has become a great pest, for its burrows often riddle the banks to such an extent as to cause them to leak, and later collapse. One can easily imagine the depredations of these creatures, when their attentions are directed to the small wells and springs which form the main water-supply of so many people in the interior. The yabbie affords an abundant food-supply to many of the larger wading birds of the western country, predominant among which is the white-fronted heron, often called 'blue crane' (*Notophoyx novae-hollandiae*).

Both this crayfish and the Murray River lobster retire to their burrows during dry seasons, and are said to be able to survive droughts by burrowing deeper than usual and forming clay-lined chambers capable of holding water for an indefinite period. The so-called 'land crayfishes' of the genus *Engaeus* also belong to this family, and are remarkably adapted for their particular mode of existence. A modification of their gill-chambers enables them to live largely out of water, and move freely on damp soil. Although independent of the actual presence of water, their burrows always occur in damp soil, and are exceedingly moist; they contain a kind of liquid mud in the chambers at their bases, wherein the crustaceans are usually found. These burrows are tubular, often reach a length of two feet, and may branch several times; when they fall in—a by no means infrequent occurrence—a 'crab-hole' is formed. In areas where the creatures occur their whereabouts is detected by the presence of large groups of mud cylinders, six to nine inches high, protruding from the surface of the ground; these are the external prolongations of their burrows, composed of dry mud. They differ from other crayfishes in having the tail portion much smaller, and adults attain a length of only four or five inches. Land crayfishes are common in parts of Tasmania, where they are known as 'land crabs;' their distribution also extends to Victoria, and they are found in the southern parts of New South Wales.

Crayfishes pass through their earlier metamorphoses while still encased within the egg; upon emerging, they remain attached to the swimmerets of the parent until they reach a well-advanced stage of development.

Members of the tribe Thalassinidea are burrowing forms with a soft, loosely-built body and a rather elongated abdomen. In some respects they form a transition to the Anomura (see HERMIT CRABS), in which group they are placed by some naturalists. The tribe is composed of three families, one of which, the Thalassinidae, includes a single form (*Thalassina anomala*), the largest and best-known of the Australian species. This crustacean occurs commonly along the coasts of northern Australia; it is especially characteristic of mangrove swamps, but is sometimes found burrowing in damp earth at a considerable distance from the sea. Although individuals are rarely observed, the large and conspicuous mounds of excavated mud which they form near their burrows are very plentiful. They are commonly dug out by the aborigines and utilized for food.

Cricket in Australia looks back through almost a century of authentic history. Its introduction is usually attributed to the officers of the *Calcutta*, which arrived in Port Jackson at the end of December 1803; Macquarie in 1821 presented 12 cricket-bats and six dozen balls to Reddall's school at Macquarie Fields; but not until 1826 is there any authentic record of matches being played. In that year the Military Cricket Club was formed: it was followed soon afterwards by the Australian, Marylebone, Union, Currency and Victoria. There was much rivalry between the early clubs, and they missed no opportunity of putting their skill to the practical test of match play. There is evidence, however, of a gilt lining to the spirit of sport that no doubt dominated many of these games. The honour of winning one match, for instance, was enhanced by the fact that the participants played for £1 per bat and a dinner each, as well as a scorer's tent valued at £3.

The *Sydney Gazette* of 2 January 1830 refers to a match played on New Year's Day 'for heavy stakes,' and states that at 'four o'clock it was estimated that there were upwards of 100 spectators witnessing the contest.' The match was played on the racecourse, now known as Hyde Park. On 17 October another match was played on the same ground for £20 a side between the Marylebone and Australian clubs, the scores (the first on record in Australia) being—

AUSTRALIAN CLUB.	*Innings.* 1st	2nd	MARYLEBONE CLUB.	*Innings.* 1st	2nd

	70	80		93	77

In 1830, too, 11 officers of the 39th regiment played 11 officers of the 57th regiment for £50 a side.

The customs and manners associated with these early games are interesting and noteworthy. The members of the Military team, for instance, play-

ed in tall black hats; the representatives of the Australian Club went into the field bareheaded, or wearing cabbage-tree hats with broad blue ribbons and streamers behind. Leg-guards and batting-gloves were not in use. The bowling was all underhand. Robert Still, a member of the Australian Club, and a native of Sydney, is said to have introduced a style of round-arm bowling that was very deadly; the credit of this innovation, however, is sometimes given to John and William Hardy, sons of Admiral Hardy. Of Still it is recorded that, because of the manner in which he 'threw' the ball, he hurt the players.

Enthusiasm soon extended beyond the mother colony, as is shown by the record of a match played at Hobart, in which an eleven drawn from H.M.S. *Hyacinth* and the 21st Fusiliers was defeated by a town team by 107 runs. This match itself might be considered the first international cricket match; but a more definite international prototype discovers itself in the match played at Hobart in 1837 between a Tasmanian team (drawn mostly from the Derwent Club) and a team of Europeans. The Hobart Town Club, founded in 1832, was the pioneer club in Tasmania, and its formation represents the first step in cricket organization there. In 1835 its name was changed to 'Derwent,' and as such it continued to hold a prominent place in the club cricket of Hobart for 70 years—until, in fact, the old clubs were superseded in 1903 by clubs founded on a district residential basis.

Sydney took the lead in establishing the system of district competitions, an organization which lies at the foundation of Australian skill in cricket. In Sydney, though the earliest clubs already mentioned flourished for some decades, not one of them has survived. The Currency Club, founded about 1840, was one of the most noteworthy for several seasons; it was entirely composed of native-born Australians, and in point of skill was far ahead of all its contemporaries. One of its founders was William Tunks, often referred to as the 'father' of good cricket in New South Wales; Harry Hilliard was also a prominent member. Of all early cricketing pioneers William Tunks is certainly most deserving of special remembrance. The Currency, however, like all the early clubs, was replaced by others, which in turn disappeared, or were superseded in 1893 by the district clubs of the present day.

In Victoria the story of club cricket is somewhat different; one club in particular stands out for its longevity, its increasing power, and its dominating influence upon the game. The Melbourne Cricket Club, founded in 1838, was reconstituted in September 1846 under the following officers:—*president*, G. Cavanagh; *honorary secretary and treasurer*, O. Gillies; *committee*, C. Burchett, A. A. Broadfoot, D. G. Campbell, F. W. Marsden, J. McLachlan and Hugh Walker. Thenceforward the club assumed in Victoria the leading position that it has maintained to the present day. Embracing as it does kindred sporting and social activities, it has now the largest membership (over 5000) of any cricket club in the Commonwealth. Up to 1910, when the visits of English teams to Australia and of Australian teams to England were placed under control of an Australian 'board of control for international cricket,' the Melbourne Club was, by virtue of its influence and wealth, a great factor in the promotion of international cricket. It survived the introduction of district cricket in Melbourne, and its representative eleven competes for the club premiership of Victoria on the same footing as those of the district clubs. Its cricket-ground, like that in Sydney (the only ground in Australia, and possibly in the world, which surpasses it), is crown land vested in trustees for cricket purposes; but, whereas in Sydney the trustees control the ground, in Melbourne they have leased it to the club, and it is managed by the club's committee. The authority of the trustees is, of course, paramount in any matter affecting the purposes for which the ground was dedicated.

For many years now the system of 'district' cricket competition, first introduced in 1893 in Sydney, has been firmly established in all the States; and it, and the organization at the back of it, are in large measure fundamentally responsible for the maintenance of a high standard of cricket in Australia. The other prime factor in keeping up the standard of play—the organization and conduct of representative cricket—presents two aspects for consideration, the domestic or inter-State, and the international.

The history of intercolonial or inter-State cricket begins with a match between Tasmania and Victoria, played at Launceston on 11 and 12 February 1851, which Tasmania won by three wickets. The scores follow:—

The return match, played at Melbourne in March 1852, was won by Victoria by 61 runs.

'It was agreed' says the Melbourne *Morning Herald*, 'that the wickets should be pitched at half past eight that the game might commence punctually at nine o'clock. At one o'clock the bugle will sound for lunch when an adjournment from the field to the tents for half an hour will take place.'

Victory again rested with Tasmania in the third meeting at Launceston in March 1854. It is significant that Tasmania, splendidly successful in two of her first three intercolonial engagements, subsequently failed to sustain that relative superiority; though her first three matches take priority over the initial New South Wales-Victoria contest, the continuity, interest in, and importance of her intercolonial contests dwindled into comparative insignificance.

The most important inter-State matches are those between New South Wales and Victoria. The first of the long and unbroken series of matches between representatives of these two States took place in March 1856. It came about directly through an advertisement in a Melbourne newspaper, inserted by some leading players of the southern capital, offering to play an eleven of New South Wales for £500. The New South Wales players, at a meeting called by William Tunks at the Currency Lass hotel on 27 January 1856, gladly and unanimously decided to accept this opportunity of measuring their skill against their Victorian challengers, though they preferred to play for the honour of the game rather than for a stake. At the meeting Tunks expressed the general opinion that to play for money was detrimental to the spirit of true sport, as it encouraged gambling, and was liable to bias the umpires. He, as it appears, was mainly responsible for raising sufficient money to pay the expenses of the New South Wales team to Melbourne, where this epoch-making match was played. The sole survivor of the two teams, David M. Serjeant—who played the first ball in what has become the greatest series of purely Australian cricket-matches—has lived in London for many years and was knighted in 1922.

The scores were:—

Umpires: J. B. Bradshaw and C. F. Cameron.

A return match played at Sydney in January of the following year saw New South Wales again victorious by 65 runs. These contests have been carried through annually (with two interruptions—see below) up to the present time (1924-5), and have been characterized by a healthy spirit of rivalry without parallel in Australia, and equalled only in the annual meetings of the rival roses—Lancashire and Yorkshire—in England. In the 1874-5 season 'home and home' matches were instituted, and this custom has been observed ever since. By winning 12 of the first 16 matches played, Victoria established an early claim to supremacy; but, after a lengthy intermediate period of fluctuating equality, New South Wales by a remarkable run of victories in the last two decades or so has restored the balance, and transferred Victoria's original lead to her own credit. There has never been a drawn or unfinished match in the whole series. Up to the end of the 1924-5 season 108 matches have been played between New South Wales and Victoria, and of these New South Wales has won 59 and Victoria 49.

The continuity of the series was interrupted in 1863 through a dispute. In the Sydney match of February 1863 S. Jones, a local batsman, was given out stumped by G. Marshall after 'over' had been called by the umpire at the bowler's end. The Victorians left the field and would not return that day. Next day, with the umpires changed, they went on with the game, though Marshall and Greaves refused to play and returned to Melbourne. New South Wales won by 84 runs. The matter was referred to the M.C.C. in London, and the authorities at Lord's decided in favour of New South Wales. No matches were played until December 1865; but the Melbourne C. C. and the Albert C. C. played two matches during the interval, one in Melbourne and one in Adelaide. The other break in continuity was occasioned by the Great War, the suspension lasting from January 1915 to December 1918.

The first match between New South Wales and South Australia was played on the Sydney cricket-ground in February 1890, and resulted in a 9-wicket victory for New South Wales. Some distinguished cricketers took part in this match, the teams including S. P. Jones, A. C. Bannerman, H. Moses, W. L. Murdoch, S. E. Gregory, T. W. Garrett, H. Donnan, W. A. Richardson, S. Deane, J. J. Ferris, and P. C. Charlton for New South Wales, and J. J. Lyons, W. F. Giffen, G. Giffen, H. Le Haldane, H. Blinman, J. Tardiff, Ballans, J. Mackenzie, A. Hill, J. C. Reedman, and F. Jarvis for South Australia. In December of the same year a return match was played in Adelaide, New South Wales again proving victorious, this time by 6 wickets. The teams did not meet again until January 1892, when South Australia won the match at Sydney by an innings and 53 runs. So brilliantly did the South

Australians acquit themselves in this engagement —and in those with Victoria and Lord Sheffield's English eleven of that season—that it was decided to admit the colony into the intercolonial competition. Thus commenced in the season 1892-3 the triangular series of contests for cricket supremacy between New South Wales, Victoria, and South Australia known as the 'Sheffield Shield' contests. This shield was presented by Lord Sheffield—who in 1891 brought out a team captained by W. G. Grace—for the encouragement of Australian cricket; and the contests for it have ever since provided the principal Australian field of first-class cricket endeavour. Annual home-and-home engagements were fixed up, and South Australia, happy in the possession of such giants of the game as George Giffen (Australia's greatest all-rounder of his period in the eighties and nineties) and Jack Lyons (Australia's greatest hitter), actually won the premiership and the shield in the season of 1893-4. Not until 16 years later, however, did South Australia again win the shield; still, South Australian matches have always been highly interesting, if only because of the presence in her elevens of such men as Joe Darling, Ernest Jones, and Clem Hill. The importance of these triangular contests arises from the fact that until quite recently they constituted practically the whole of first-class cricket for the Australian season, and were the only avenues leading to the goal of every cricketer's ambition—inclusion in an Australian representative eleven. In that respect they may still be regarded as the chief trial games, since international selection depends almost entirely upon the form displayed and success achieved in these matches. Up to the end of the season 1924-5 the shield has been won three times by South Australia, ten times by Victoria and 16 times by New South Wales. Inclusive of the results in these and previous engagements with New South Wales, South Australia has, up to the end of the 1924-5 season, won 15 matches as against 44 by New South Wales. From January 1915 to December 1919 no matches were played between New South Wales and South Australia.

Victoria and South Australia first met at Adelaide in 1874, the South Australians taking the field with 18 men. Victoria won this match by 15 runs; but two years later, in a return engagement (also played at Adelaide), the tables were turned, South Australia winning by an innings and 70 runs. The teams met again on even terms (11 men a side) in 1880 at Melbourne, and victory went to Victoria by 7 wickets. In all, and including these contests up to the end of the 1924-5 season, 73 matches have been played between the two States, 49 of which have been won by Victoria and 24 by South Australia.

In Queensland cricket made slow headway for many years. Beginning in 1864 with a team of 22 against a New South Wales eleven, Queensland played ten matches with odds against the mother-colony before venturing on her first eleven-a-side match in 1893; of these ten each colony won four, and two were drawn. During recent years, however, Queensland has made great progress, and is advancing strong claims for inclusion in the Sheffield Shield competition. With New South Wales she has played on even terms 45 matches, winning eight; her record against Victoria is ten matches with one win.

From time to time matches have been played by teams from the eastern States against elevens of Western Australia, but up to the present the standard of play has not nearly reached the Sheffield Shield level. Geographically Western Australia has been at a great disadvantage, but since the completion of the transcontinental railway the way is open for a more frequent exchange of visits. It is only by these that the standard of play in the west can be materially improved. Against New South Wales six matches have been played for one victory, against Victoria seven for one.

Though Tasmanian cricket has a long and authentic history—probably the longest in Australia—the game has never reached the same high standard of enthusiasm, enterprise and skill as on the mainland. There is evidence, however, that a great deal of cricketing skill has been locked up in the little island for want of opportunity to develop. The first three intercolonial matches with Victoria in 1851, 1852, and 1854, have been already referred to; they were followed by an irregular series of games beginning in 1866, in which Tasmania was represented by 16 men; of these Victoria won the first, and Tasmania the second and third. From 1871 onwards the matches were played on level terms, though not against Victoria's best, alternately in Melbourne and Launceston or Hobart. Up to and including the 1923-4 season 38 matches have been played (including those in which Tasmania played with odds), Victoria having won 24 and Tasmania 13; one was drawn. Against New South Wales the first match was played at Sydney in 1897; there have been only six additional contests, one of which (that played in 1905 at Hobart) Tasmania won. Many fine individual performances stand to the credit of Tasmanian players in representative cricket—for example, C. J. Eady's 116 and 112 not out in the same match against Victoria in 1895; but nowadays the second elevens of both New South Wales and Victoria are regarded as quite strong enough to engage the best of Tasmania. Tasmanian cricket labours under certain natural disadvantages. Its insular position shuts it off from easy intercourse with the mainland, and from regular example of the best Australian cricketing models. Further, the scattered distribution of the population is a drawback financially, and blocks the promotion of internal sodality, which is of the utmost importance in the encouragement of educational visits to and from outside cricketing centres. Among the leading Tasmanian cricketers were George Bailey (who went to England in 1878 with the first Australian combination), T. Kendall (the left-hand bowler who played in a preliminary Australian tour with the 1878 Australian eleven), K. E. Burn (a member of the 1890 Australian team to England, and probably the best batsman Tasmania has produced), C. J. Eady (the giant all-rounder, a member of the 1896 Australian team in England, who once made the huge score of 566 in an innings that lasted 7 hours 55 minutes in a competition club match for Break-o'-Day against Wellington at Hobart in 1920), E. A. Windsor, an all-rounder, R. P. Hawson, a fine left-handed batsman, and E. A. McDonald, the fast bowler who migrated to Victoria and now resides in England.

The dominant feature of New Zealand cricket is its 'splendid isolation,' both in domestic and foreign relationships. The history of New Zealand cricket is largely the story of attempts to surmount geographical and climatic drawbacks. The game has never been lacking in enthusiasm; indeed New Zealand cricket history abounds with records of personal endeavour and

beneficence. The outstanding cricketer of the Dominion was Dan Reese (Canterbury), the only player in New Zealand representative cricket who made 2000 runs and took 150 wickets. Among leading batsmen A. B. Williams (Wellington) deserves special mention; the most famous bowlers were A. Downes and A. H. Fisher of Otago. Trials of strength with New South Wales and Victoria have been against second elevens of these States. The first contest with New South Wales took place in 1894, and only three games have been played since, one of which was won by New Zealand. Against Victoria three matches have been played; two were lost by New Zealand and one was drawn. On several occasions Australian teams have visited New Zealand, but the matches have been rather exhibitions than serious contests. Educative visits have also been made by English amateur teams, and in virtue of these periodical visits, and with the assistance of imported coaches, the standard of the game in the Dominion is steadily on the up-grade.

A match of the pre-district days which should not be forgotten was played in February 1867 by the Albert Club of Sydney against a team of aboriginals—by name Bullocky, Mullagh, Tiger, King Cole, Red Cap, Peter Jim Crow, Twopenny, Charlie, Cozens, Mosquito, Dick-a-Dick, and Tarpot, with a white man, Charlie Lawrence, as thirteenth man. The Alberts scored 298 runs and the aboriginals 164, and when the match ended early on the third day spectators were given a display of throwing the spear, boomerang, and cricket-ball. The team was afterwards taken to England, where it had some success.

International Cricket.—Though the domestic history of cricket in Australia is fairly lengthy, it is by international matches that it is best known to the world at large. The first 'All England' eleven was brought out in the season of 1861-2 by the well-known catering firm of Spiers and Pond; it consisted of H. H. Stephenson (Surrey, captain), G. Bennett (Kent), W. Caffyn (Surrey), G. Griffith (Surrey), T. Hearne (Middlesex), R. Iddison (Yorkshire), C. Lawrence (Kent), W. Mortlock (Surrey), W. Mudie (Surrey), T. Sewell (Surrey), E. Stephenson (Yorkshire), and G. Wells (Middlesex). It played 12 matches, all against odds, winning six, losing two, and drawing four. The first was played on 1 January 1862 at Melbourne, the English team meeting 18 of Victoria. England scored 305, and the eighteen 118 and 91. The first match against a combined Australian team —22 players selected from Victoria and New South Wales—was played at Melbourne on 17 and 18 January; it resulted in a draw, the twenty-two scoring 153 and 144 against 110 and 10 for no wickets by the All-England eleven. This match was followed by another against 22 New South Wales players at Sydney on 29 January; the Englishmen won by 49 runs, scoring 175 and 66 to 127 and 65. A trip to Hobart followed, during which Tasmania was defeated. Returning to Victoria, the Englishmen played a draw with a Victorian twenty-two, the captain of the latter team adhering to an agreement that the match was not to extend beyond four days. The Victorians had scored 140 and 151 and England 218 and 63 for 7 wickets. In the return match with the combined twenty-two they were beaten by 12 wickets. The members of the English team planted 12 elms, some of which still afford shelter at the Melbourne cricket-ground.

The warm welcome given to these players, and the local enthusiasm for the game, created a desire among English cricketers to revisit Australia, and in 1863-4 George Parr toured the colonies with a side that won against odds all its finished matches—the only team that has never been defeated in Australia. Six matches were drawn. The team included E. M. Grace, then one of the most brilliant batsmen in England. He figured in several single-wicket matches; on one occasion playing against six of Maryborough, he won the toss and stayed in all day for 106 runs.

Ten years elapsed before a third team visited Australia, this time under the captaincy of W. G. Grace, the greatest cricketer of any period. In the interim Australians had made great strides in the game. William Caffyn, who had come out with Stephenson's and Parr's teams, and Charles Lawrence, who had been one of Stephenson's team, were in 1864 engaged as coaches in Sydney. Caffyn was a brilliant batsman, the Trumper of his time. He went into business in Sydney as a hairdresser, and combined this with cricket-coaching on the Domain; in 1872 he returned to England, and died in 1919. Lawrence settled down in Australia. Caffyn and Lawrence both played for New South Wales in intercolonial matches. Their influence on the game was so important that when Grace's team came out in 1873-4 it was thrice defeated. Three years later James Lillywhite's team discovered a still more pronounced improvement; they played twelve matches against odds, and won four only, three being lost and five drawn. As a result New South Wales, having twice beaten them with odds, played against them the first eleven-a-side match in Australia against an English eleven. This was followed up by the first test match, which Australia won. Details of these historic contests are given below; it must be remembered that until 1887 in Australia and 1889 in England there were only 4 balls to the over.

LILLYWHITE'S TEAM V. NEW SOUTH WALES.

Umpires: Curtis Read and B. Terry.

The fifth team was brought to Australia by Lord Harris in 1878-9—a fine combination, mainly amateurs, with two Yorkshire professionals, T. Emmett and G. Ulyett. They played five matches on even terms, and were defeated three times. Alfred Shaw led the next team (1881-2), composed of professionals; it won three of the five finished matches. It was after that campaign that the 1882 Australian eleven defeated, at the Oval, the full strength of England. In 1882 Ivo Bligh set out after the 'ashes,' and his team won four of its seven matches. Then followed two professional teams, Alfred Shaw (1884-5) captaining the first and Arthur Shrewsbury (1886-7) the next. In 1887-8 rival teams visited Australia. C. A. Smith, a noted amateur, captained one which was organized with the patronage of the Sydney authorities; Melbourne invited a team under M. B. Hawke (afterwards Lord Hawke). Financial failure dogged both teams; for a few years English visits ceased, and Australian cricket, which had had five visiting teams in six years, was able to recover. Four years later, in 1891, Lord Sheffield laid Australia under a debt of gratitude by organizing at great expense a powerful team which, though captained by W. G. Grace, was beaten in two of the three tests. Lord Sheffield further stimulated Australian cricket by donating the shield already mentioned.

In 1894 the Sydney Cricket-ground Trust and the Melbourne C. C. joined forces and brought out the next team which, captained by A. E. Stoddart, won the rubber against Australia. In 1897-8 Stoddart's second team lost the 'ashes' after a memorable series of matches. K. S. Ranjitsinhji and A. C. MacLaren batted with wonderful success and brilliancy, and captivated the public to a greater degree than had any earlier English batsmen. It was under Stoddart, too, that Australia saw the two great fast bowlers, T. Richardson and W. H. Lockwood. Subsequent teams were captained by A. C. MacLaren (1901-2), P. F. Warner (1903-4), A. O. Jones (1907-8), P. F. Warner again (1911-12), J. W. H. T. Douglas (1920-1), and A. E. R. Gilligan (1924-5). Up to the end of the 1924-5 tour test matches in Australia produced for the English teams 24 wins, 36 defeats, and 2 draws.

Two English teams which were specially organized to play in New Zealand have also played matches in Australia. Lord Hawke's team (1902-3) under the captaincy of P. F. Warner lost two matches and drew one. A. C. MacLaren's (1922-3) lost three and drew three.

Australian teams in England.—The success of the Australian players against Lillywhite's team in 1876-7 inspired the cricketers of that period to form a team to invade England. The project did not enlist much practical support from the public, but the team played a number of matches in Australia and New Zealand before setting out, and then defrayed their own expenses to England. When they had defeated the M.C.C. at Lord's in one day—and in doing so had dismissed what was practically the full strength of England for 19 runs—and won other splendid victories the Australian people took up the team, and on its return gave it a national welcome. No 'test' match (in the technical sense) was played by this team; but the M.C.C. match took the place of one in the public mind.

The outstanding features of the play were the superb bowling of Spofforth and Boyle, the batting of C. Bannerman, the wicket-keeping of Blackham, and the leadership of D. W. Gregory.

1878 AUSTRALIAN ELEVEN v. M.C.C. AND GROUND.

At Lord's, 27 May 1878. Australian Eleven won by 9 wickets.

Umpires: Rylott and Sherwin.

When the second Australian eleven went to England in 1880, they were received coldly at headquarters, because of a riot that had taken place on the Sydney ground during the match between Lord Harris's 1878-9 team and New South Wales. However, Lord Harris eventually buried the hatchet, and the team played one test match with England at Kennington Oval; England scored 420, W. G. Grace making 152; Australia was all out for 149, but in the second innings scored 327, W. L. Murdoch going through for 153 not out. England lost five wickets in getting the 57 required to win, G. Palmer and H. F. Boyle bowling brilliantly. Unfortunately Australia was deprived of the services of Spofforth, who had been injured in a previous match.

The second team that Murdoch captained (1882) vanquished the full strength of England at Kennington Oval in what was styled the greatest match ever played up to that time. It was the only test match of the tour.

In *Surrey Cricket: Its History and Associations* by Lord Alverstone and C. W. Alcock, the secretary of the Surrey County C. C. thus pictured the finish of this remarkable match:—

The crowning feature of the tour for the Australians was their historic victory over England at the Oval. It was a bowler's wicket from the start, and the English side were able, though they scored only 101, to head their opponents by 38 runs. H. H. Massie's brilliant hitting stood the Australians in good stead when they began their second innings. Taking full advantage of the chance before the wicket had got very difficult again, he scored 55 out of a total of 122. With only 85 to get to win England seemed to have the victory assured. With 51 up for only two wickets, and W. G. Grace and Ulyett well in, the result was apparently a certainty. Thirty-four still to win and seven good wickets to fall! Then, after a hit for 2, W. G. was easily taken at mid-off, having made 32—an invaluable score. The Hon. Alfred Lyttelton and A. P. Lucas were now together, and with twelve maiden overs in succession and two batsmen both able to hit if they liked, the spectators began to realize that the issue was by no means certain. The tension grew acute as it was seen how difficult it was to get the ball away. Spofforth and Boyle were keeping an irreproachable length. Blackham, without anyone behind him, and Spofforth bowling his hardest, was as steady as the old guard at the wicket. It was wonderful all-round cricket. The excitement was intense as the agony was prolonged, and one could almost hear one's own heart beat. It was a terribly anxious time, and no wonder. Some of the younger batsmen on the English side still to come in were nervous. When Lyttelton was bowled 19 runs were wanted with half the wickets still in hand, and with 9 added two more batsmen went. With only 10 to get three hits would have settled the matter. Murdoch has since said that his only fear at the crisis was that some one would have a go at Boyle. This bowler was keeping a wonderful length, and to hit him would have been risky, of course. But there was no attempt to hit, and Boyle, dismissing the last two batsmen, gave the Australians their first victory over England in England by 7 runs. It was a glorious finish, and the Australians thoroughly deserved their honours.

Umpires: R. Thom and L. Greenwood.

The 1884 Australian eleven, the third captained by W. L. Murdoch, was also a fine all-round combination. Three test matches were played, the first and last being drawn in favour of Australia, but England won the Lord's match by an innings and five runs. It was in the third match, at Kennington Oval, that Australia scored 551 runs, W. L. Murdoch making 211, P. S. McDonnell 103, and H. J. H. Scott 104.

The next four Australian teams showed a falling off in standard, and many defeats were inflicted on them. The 1888, 1890 and 1893 teams lost 40 matches and won only 49, and the 1886 team won only nine matches out of 16. But every team since—save that captained by S. E. Gregory in 1912, which many of the more notable players declined to join (partly owing to a difference with the board of control)—has proved a great combination; and it has long been realized that the pupil has become as proficient as the master. Of test matches played in England the home teams have won 17, the Australians 11, and 19 have been drawn.

*Won, Lost, Drawn.

The A.I.F. team in 1919 played 32 matches in England, winning 13, losing 4, and drawing 15.

PERSONNEL OF AUSTRALIAN TEAMS IN ENGLAND.

First (1878).—D. W. Gregory (captain), F. E. Allen, G. H. Bailey, C. Bannerman, A. C. Bannerman, T. Horan, W. E. Midwinter, T. W. Garrett, J. M. Blackham, F. R. Spofforth, H. F. Boyle, W. L. Murdoch, with John Conway, manager.

Second (1880).—W. L. Murdoch (captain), J. M. Blackham, F. R. Spofforth, A. C. Bannerman, H. F. Boyle, G. J. Bonnor, G. E. Palmer, P. S. McDonnell, G. Alexander (player and manager), A. H. Jarvis, T. U. Groube, W. H. Moule, and J. Slight.

Third (1882).—W. L. Murdoch (captain), T. Horan, T. W. Garrett, J. M. Blackham, F. R. Spofforth, A. C. Bannerman, H. F. Boyle, G. J. Bonnor, G. E. Palmer, P. S. McDonnell, G. Giffen, S. P. Jones, H. H. Massie, with C. W. Beal, manager.

Fourth (1884).—W. L. Murdoch (captain), W. E. Midwinter, J. M. Blackham, F. R. Spofforth, A. C. Bannerman, H. F. Boyle, G. J. Bonnor, G. E. Palmer, P. S. McDonnell, G. Giffen, H. J. H. Scott, W. H. Cooper, with G. Alexander, manager.

Fifth (1886).—H. J. H. Scott (captain), T. W. Garrett, J. M. Blackham, F. R. Spofforth, G. J. Bonnor, G. E. Palmer, A. H. Jarvis, G. Giffen, S. P. Jones, W. Bruce, E. Evans, J. McIlwraith, J. W. Trumble, with Major B. J. Wardill, manager.

Sixth (1888).—P. S. McDonnell (captain), G. J. Bonnor, G. H. S. Trott, A. C. Bannerman, S. P. Jones, C. T. B. Turner, J. J. Lyons, J. D. Edwards, A. H. Jarvis, J. J. Ferris, J. Worrall, J. M. Blackham, H. F. Boyle, with C. W. Beal, manager. S. M. J. Woods, a Sydney man at Cambridge University, played six matches with this team.

Seventh (1890).—W. L. Murdoch (captain), J. J. Lyons, G. H. S. Trott, J. M. Blackham, F. H. Walters, S. P. Jones, C. T. B. Turner, J. E. Barrett, J. J. Ferris, S. E. Gregory, P. C. Charlton, K. E. Burn, H. Trumble, with H. F. Boyle, manager.

Eighth (1893).—J. M. Blackham (captain), J. J. Lyons, H. Graham, A. C. Bannerman, W. Bruce, S. E. Gregory, G. H. S. Trott, A. Coningham, H. Trumble, R. W. McLeod, G. Giffen, C. T. B. Turner, W. F. Giffen, A. H. Jarvis, with Victor Cohen, manager.

Ninth (1896).—G. H. S. Trott (captain), S. E. Gregory, J. Darling, C. Hill, F. A. Iredale, G. Giffen, H. Donnan, H. Trumble, H. Graham, J. J. Kelly, A. E. Johns, C. J. Eady, E. Jones, T. R. McKibbin, with H. Musgrove, manager.

Tenth (1899).—J. Darling (captain), C. Hill, M. A. Noble, J. Worrall, V. Trumper, F. Laver, F. A. Iredale, H. Trumble, S. E. Gregory, J. J. Kelly, E. Jones, C. E. McLeod, W. P. Howell, A. E. Johns, with Major B. J. Wardill, manager.

Eleventh (1902).—J. Darling (captain), V. Trumper, M. A. Noble, C. Hill, R. A. Duff, W. W. Armstrong, A. J. Hopkins, S. E. Gregory, H. Trumble, J. J. Kelly, E. Jones, H. Carter, W. P. Howell, J. V. Saunders, with Major J. B. Wardill, manager.

Twelfth (1905).—J. Darling (captain), M. A. Noble, V. Trumper, W. W. Armstrong, C. Hill, A. J. Hopkins, R. A. Duff, S. E. Gregory, D. R. A. Gehrs, C. E. McLeod, J. J. Kelly, A. Cotter, F. Laver (player and manager), P. M. Newland, and W. P. Howell.

Thirteenth (1909).—M. A. Noble (captain), V. Trumper, S. E. Gregory, W. Bardsley, W. W. Armstrong, V. S. Ransford, P. A. McAlister, C. G. Macartney, R. J. Hartigan, H. Carter, A. J. Hopkins, J. A. O'Connor, A. Cotter, W. Carkeek, W. J. Whitty, with F. Laver, player and manager.

Fourteenth (1912).—S. E. Gregory (captain), W. Bardsley, C. G. Macartney, C. Kelleway, C. B. Jennings, E. R. Mayne, R. B. Minnett, J. T. Matthews, H. Webster, S. H. Emery, D. Smith, W. J. Whitty, W. Carkeek, J. W. McLaren, G. R. Hazlitt, with G. S. Crouch as manager for the board of control.

Fifteenth (1921).—W. W. Armstrong (captain), H. L. Collins, W. Bardsley, C. G. Macartney, H. Carter, J. M. Taylor, J. M. Gregory, W. A. Oldfield, E. A. McDonald, T. J. Andrews, H. L. Hendrey, J. S. Ryder, A. Mailey, C. E. Pellew, and E. R. Mayne, with Sydney Smith, jr., as manager for the board of control.

1878-9.—Lord Harris (captain), C. A. Absolom, L. Hone, A. N. Hornby, A. P. Lucas, F. A. Mackinnon, H. C. Maul, F. Penn, V. F. Royle, S. S. Schultz, A. J. Webbe, T. Emmett, and G. Ulyett.

1881-2.—A. Shaw (captain), T. Emmett, G. Ulyett, R. G. Barlow, W. Bates, W. E. Midwinter, E. Peate, R. Pilling, W. H. Scotton, A. Shrewsbury, J. Selby, and J. Lillywhite.

1882-3.—Ivo Bligh (now Lord Darnley, captain), C. F. H. Leslie, W. W. Read, A. G. Steel, C. T. Studd, G. B. Studd, E. F. S. Tylecote, G. F. Vernon, R. G. Barlow, W. Bates, W. Barnes, and F. Morley.

1884-5.—A. Shaw (captain), G. Ulyett, W. Bates, W. H. Scotton, A. Shrewsbury, W. Barnes, James Lillywhite, W. Attewell, J. Briggs, W. Flowers, J. Hunter, R. Peel, and J. M. Read.

1886-7.—A. Shrewsbury (captain), R. G. Barlow, W. Bates, W. H. Scotton, A. Shaw, W. Barnes, James Lillywhite, J. Briggs, W. Flowers, J. M. Read, W. Gunn, G. A. Lohmann, and M. Sherwin.

1887-8.—M. B. Hawke (captain), G. F. Vernon (captain after M. B. Hawke was recalled to England on the death of his father, Lord Hawke), W. W. Read, M. P. Bowden, A. E. Stoddart, A. E. Newton, T. C. O'Brien, W. Bates, R. Peel, J. T. Rawlin, W. Attewell, J. Beaumont, and R. Abel.

1887-8.—C. A. Smith (captain), A. Shrewsbury, G. A. Lohmann, J. M. Read, J. Briggs, R. Pilling, G. Ulyett, J. M. Preston, W. Newham, G. Brann, L. C. Docker, A. D. Pougher, and James Lillywhite.

1891-2.—W. G. Grace (captain), A. E. Stoddart, G. MacGregor, O. G. Radcliffe, H. Philipson, G. A. Lohmann, R. Abel, J. M. Read, J. W. Sharpe, W. Attewell, R. Peel, J. Briggs, and G. Bean.

1894-5.—A. E. Stoddart (captain), A. C. MacLaren, F. G. J. Ford, H. Philipson, L. H. Gay, T. Richardson, W. Brockwell, W. H. Lockwood, A. Ward, J. Briggs, R. Peel, J. T. Brown, and Walter Humphreys (Sussex).

1897-8.—A. E. Stoddart (captain), K. S. Ranjitsinhji, A. C. MacLaren, T. Hayward, W. Storer, N. F. Druce, E. Wainwright, J. R. Mason, J. H. Board, G. H. Hirst, J. Briggs, J. T. Hearne, and T. Richardson.

1901-2.—A. C. MacLaren (captain), T. Hayward, J. T. Tyldesley, L. C. Braund, W. G. Quaife, C. Robson, A. A. Lilley, C. McGahey, G. L. Jessop, A. O. Jones, S. F. Barnes, J. Gunn, C. Blythe, and H. G. Garnett.

1903-4.—P. F. Warner (captain), R. E. Foster, T. Hayward, J. T. Tyldesley, G. H. Hirst, A. A. Lilley, E. Arnold, W. R. Rhodes, L. C. Braund, A. E. Knight, B. J. T. Bosanquet, A. Fielder, and A. E. Relf, with J. A. Murdoch, manager for the M.C.C.

1907-8.—A. O. Jones (captain), F. L. Fane, K. L. Hutchings, J. N. Crawford, R. A. Young, W. R. Rhodes, L. C. Braund, E. G. Hayes, J. B. Hobbs, C. Blythe, A. Fielder, J. Hardstaff, J. Humphries (Derbyshire), and S. F. Barnes, with Major Philip Trevor, manager for the M.C.C. George Gunn came out as a visitor and acted as scorer in the early matches, but joined the team on the eve of the first test match and so headed the batting averages for the tour.

1911-2.—P. F. Warner (captain), J. W. H. T. Douglas (vice-captain), F. R. Foster, J. B. Hobbs, W. R. Rhodes, F. E. Woolley, S. F. Barnes, J. W. Hearne, G. Gunn, E. J. Smith, C. P. Mead, J. W. Hitch, H. Strudwick, S. P. Kinnier, J. Vine, and J. Iremonger, with T. Pawley, manager for the M.C.C.

1920-1.—J. W. H. T. Douglas (captain), E. R. Wilson (vice-captain), P. G. H. Fender, J. B. Hobbs, W. R. Rhodes, F. E. Woolley, J. W. Hearne, J. W. Hitch, H. Strudwick, E. Hendren, A. C. Russell, H. Makepeace, C. Parkin, H. Howell, A. Waddington, C. Dolphin, with F. C. Toone (Yorkshire), manager for the M.C.C.

1924-5.—A. E. R. Gilligan (captain), J. W. H. T. Douglas, L. J. Bryan, A. P. F. Chapman, J. B. Hobbs, E. Hendren, F. E. Woolley, J. W. Hearne, H. Strudwick, H. Sutcliffe, R. Kilner, W. W. Whysall, M. W. Tate, A. P. Freeman, R. Tyldesley, H. Howell, H. Sandham, with F. C. Toone, manager for the M.C.C.

L.O.S.P.
J.C.D.

Crickets, insects of the family Gryllidae, belonging to the order Orthoptera, closely related to the long-horned grasshoppers (q.v.), and represented in Australia by about 50 species. The musical apparatus of the male cricket consists of a stridulating file on the lower surface of the wing-covers, whose rapid vibration causes the edge of one cover to rasp the file of the other.

The Black Cricket (*Gryllus commodus*) is the commonest and most widely distributed species in Australia. Almost black, about an inch in length, the male makes a very distinctive chirruping noise. It is especially prevalent in the vicinity of water, and sometimes damages vines by biting through the stem of a bunch of grapes.

The Mole-cricket (*Gryllotalpa coarctata*), though seldom seen, is frequently heard; it is of a dingy yellowish-brown colour, with powerful front-legs adapted for burrowing, and lives during the day underground, or beneath stones or logs. When alarmed, it ejects an offensive black liquid from its mouth. It nibbles the roots of fruit-trees, and sometimes eats large holes in turnips and potatoes.

The Cylindrical Cricket (*Cylindracheta Kochii*), though seldom seen, occurs in many parts of Australia; it seriously injures the roots of fruit-trees, and is destructive to greenhouse plants, the body being specially adapted for burrowing in plant-stems; while the excavating legs are at work, the middle and hind-legs are closely packed against the abdomen.

Many Australian crickets of the genera *Gryllacris*, *Paragryllacris*, and *Eonius* (belonging to the family Phasgonuridae, the long-horned grasshoppers or tree crickets) are carnivorous. They hide in crevices in trees, or in tunnels made by wood-boring insects, especially in the flowering-stems of grass-trees (*Xanthorrhoea*); one species in north-western Australia makes an underground chamber, the mouth of which it

covers with glutinous threads. They feed at night and, being armed with powerful jaws, can inflict rather severe bites. In the female the ovipositor is about the length of the body, and in both sexes the antennae are much longer. The domestic 'cricket on the hearth' is an introduced cosmopolitan species, *Gryllus domesticus*. See ORTHOPTERA. A.M.L.

Crocodiles, vernacular name of reptiles of the family Crocodilidae, which contains the largest living reptile, the estuarine or salt-water crocodile (*Crocodilus porosus*). Its average length is about 18 feet; but one killed at Barisal in Bengal is said to have been 33 feet long, and J. D. Ogilby quotes a measurement of 32 feet for one shot in the Pioneer River in Queensland. This species is found from India and southern China through Malaysia and the northern coasts of Australia and Papua to the Fiji Islands, both in estuaries and in the upper (freshwater) channels, and occasionally far out at sea; a specimen shot in the Mary River (Queensland) represents its most southerly range. Fossil remains of a larger species have been found near Brisbane and on the Darling Downs. The freshwater crocodile (*Crocodilus johnstoni*), which is only known to occur in northern Queensland and the Northern Territory, grows to about seven feet; it has a more slender snout, and its head is not so rough above as that of the coastal species; the plates on the neck are also different, the series being almost continuous with the other enlarged dorsal plates. It is also comparatively harmless, and feeds principally on fish. As the aborigines put it, the sea-going crocodile is 'cheeky fellow' and would 'round you up,' but the freshwater crocodiles in the land-locked pools are 'frightened fellow,' and their eggs can be stolen with impunity.

The entire body of a crocodile is clothed with scales, the back being protected with bony plates. The elongated mouth is armed with conical teeth on each side of both upper and lower jaws. In the large (sea-going) species there are usually 18 upper and 15 lower teeth on each side; in the freshwater species there may be as many as 20 upper and 17 lower. There are five digits on each fore-limb and four on each hind-limb, the latter being largely webbed. The tail is long and very muscular.

A curious adaption to aquatic life may be seen in the nostrils; the external openings are on the tip of the snout, and the air-passages are prolonged to the back of the lengthy mouth. A crocodile is thus able to hold and drown its prey under water, itself being able to breathe meanwhile so long as the snout is above the surface. Crocodiles will devour almost any animal they can secure, including young cattle, marsupials, reptiles, water-fowl, and occasionally human beings. When motionless, and lying partly under water, they resemble floating logs, and are thus able to approach unalert prey. They have been known to travel a considerable distance overland to a neighbouring stream. Although usually silent, there is evidence that they can emit a hoarse bellow which has been compared with that of an angry bull. In captivity a specimen has been known to stay under water without breathing for 20 minutes.

The name 'alligator,' often applied to Australian crocodiles, is quite incorrect. True alligators are only to be found in the southern States of North America, and in China. In our crocodiles the fourth tooth on each side of the lower jaw is much enlarged, and fits into a notch in the upper jaw, being thus plainly visible when the mouth is closed. In alligators a similar tooth fits into a pit within the border of the upper jaw; the typical alligator, moreover, has a more rounded head, and is more sluggish than the voracious crocodile with its pointed snout.

Crocodiles are oviparous. In the coastal species the number of eggs varies from 20 to 80; they are white, varying considerably in dimensions, the average being about the size of those of a duck, but more elongated. J. MacGillivray gives the following description of a nest on the banks of the Claudie River, at Lloyd's Bay in northern Queensland:—'A crocodile's nest was noted on the right bank, in the mangrove portion, and we landed to examine it. The mangroves were small, the bank about 18 inches above high-tide mark, and the nest 8 feet in from the water's edge. It had a base diameter of about 4½ feet, and 2 feet across the top; it was 3 feet high, composed of decaying vegetation and sand. Uncovering it, the eggs, 43 in number, were found within a foot of the top, all in a heap. A piece of stick was laid across the middle of the eggs —whether by accident or design it is hard to say; but the blacks aver that it is always so.' Newly-hatched specimens are very lively at times, and snap in a vicious manner. They are about ten inches in length. Up to the present, little or no economic use has been made of the skins of either of our Australian crocodiles. H.A.L.

Crook. WILLIAM PASCOE (1775-1846), born at Dartmouth in Devon on 29 April 1775, and during his youth employed in domestic service and tin-working, was accepted by the London Missionary Society (then known as 'The Missionary Society') and sent with a mission party destined for Tahiti, Tonga, and the Marquesas group, leaving England on 10 August 1796. Despite the hostility of the natives, which drove his companions to Australia, Crook worked on in the Marquesas until in 1799 he was recalled to England. Still desiring a missionary career, he was in April 1803 despatched by the Society (which the then colonial secretary, Lord Hobart, seems to have confused with the Society for the Propagation of the Gospel) to take up mission work in the projected settlement under Collins at Port Phillip; that being abandoned, he came on in November to Port Jackson, and was employed as a teacher in the school at Parramatta, with liberty to preach once a fortnight at Ryde and Castle Hill. King next sent him as storekeeper for Paterson's abortive attempt to settle on the Tamar, but cancelled the appointment when the expedition proved a failure, and allowed him to resume his teaching, so that he was able to open a day and boarding-school at Parramatta. During the rule of Bligh's opponents he was employed by them in lieu of Henry Fulton to conduct divine service and baptize; he therefore moved to Sydney, and opened a school at the corner of Hunter- and Bligh-streets—the first boarding-school in Sydney. Reverting to private life on Macquarie's arrival, he on 27 August 1810 joined other missionaries who had been driven from the islands in founding a Congregational Church for Australia, and at once was rebuked by Macquarie at Marsden's instigation for administering the Lord's Supper while an unlicensed and unordained clergyman. At the end of 1815 Crook (on Marsden's recommendation) was appointed by the London Missionary Society to Moorea (and later t Tahiti) in the Society Islands, where he did missionary and medical work for 15 years; on his return to

1886-7.—A. Shrewsbury (captain), R. G. Barlow, W. Bates, W. H. Scotton, A. Shaw, W. Barnes, James Lillywhite, J. Briggs, W. Flowers, J. M. Read, W. Gunn, G. A. Lohmann, and M. Sherwin.

1887-8.—M. B. Hawke (captain), G. F. Vernon (captain after M. B. Hawke was recalled to England on the death of his father, Lord Hawke), W. W. Read, M. P. Bowden, A. E. Stoddart, A. E. Newton, T. C. O'Brien, W. Bates, R. Peel, J. T. Rawlin, W. Attewell, J. Beaumont, and R. Abel.

1887-8.—C. A. Smith (captain), A. Shrewsbury, G. A. Lohmann, J. M. Read, J. Briggs, R. Pilling, G. Ulyett, J. M. Preston, W. Newham, G. Brann, L. C. Docker, A. D. Pougher, and James Lillywhite.

1891-2.—W. G. Grace (captain), A. E. Stoddart, G. MacGregor, O. G. Radcliffe, H. Philipson, G. A. Lohmann, R. Abel, J. M. Read, J. W. Sharpe, W. Attewell, R. Peel, J. Briggs, and G. Bean.

1894-5.—A. E. Stoddart (captain), A. C. MacLaren, F. G. J. Ford, H. Philipson, L. H. Gay, T. Richardson, W. Brockwell, W. H. Lockwood, A. Ward, J. Briggs, R. Peel, J. T. Brown, and Walter Humphreys (Sussex).

1897-8.—A. E. Stoddart (captain), K. S. Ranjitsinhji, A. C. MacLaren, T. Hayward, W. Storer, N. F. Druce, E. Wainwright, J. R. Mason, J. H. Board, G. H. Hirst, J. Briggs, J. T. Hearne, and T. Richardson.

1901-2.—A. C. MacLaren (captain), T. Hayward, J. T. Tyldesley, L. C. Braund, W. G. Quaife, C. Robson, A. A. Lilley, C. McGahey, G. L. Jessop, A. O. Jones, S. F. Barnes, J. Gunn, C. Blythe, and H. G. Garnett.

1903-4.—P. F. Warner (captain), R. E. Foster, T. Hayward, J. T. Tyldesley, G. H. Hirst, A. A. Lilley, E. Arnold, W. R. Rhodes, L. C. Braund, A. E. Knight, B. J. T. Bosanquet, A. Fielder, and A. E. Relf, with J. A. Murdoch, manager for the M.C.C.

1907-8.—A. O. Jones (captain), F. L. Fane, K. L. Hutchings, J. N. Crawford, R. A. Young, W. R. Rhodes, L. C. Braund, E. G. Hayes, J. B. Hobbs, C. Blythe, A. Fielder, J. Hardstaff, J. Humphries (Derbyshire), and S. F. Barnes, with Major Philip Trevor, manager for the M.C.C. George Gunn came out as a visitor and acted as scorer in the early matches, but joined the team on the eve of the first test match and so headed the batting averages for the tour.

1911-2.—P. F. Warner (captain), J. W. H. T. Douglas (vice-captain), F. R. Foster, J. B. Hobbs, W. R. Rhodes, F. E. Woolley, S. F. Barnes, J. W. Hearne, G. Gunn, E. J. Smith, C. P. Mead, J. W. Hitch, H. Strudwick, S. P. Kinnier, J. Vine, and J. Iremonger, with T. Pawley, manager for the M.C.C.

1920-1.—J. W. H. T. Douglas (captain), E. R. Wilson (vice-captain), P. G. H. Fender, J. B. Hobbs, W. R. Rhodes, F. E. Woolley, J. W. Hearne, J. W. Hitch, H. Strudwick, E. Hendren, A. C. Russell, H. Makepeace, C. Parkin, H. Howell, A. Waddington, C. Dolphin, with F. C. Toone (Yorkshire), manager for the M.C.C.

1924-5.—A. E. R. Gilligan (captain), J. W. H. T. Douglas, L. J. Bryan, A. P. F. Chapman, J. B. Hobbs, E. Hendren, F. E. Woolley, J. W. Hearne, H. Strudwick, H. Sutcliffe, R. Kilner, W. W. Whysall, M. W. Tate, A. P. Freeman, R. Tyldesley, H. Howell, H. Sandham, with F. C. Toone, manager for the M.C.C.

L.O.S.P.
J.C.D.

Crickets, insects of the family Gryllidae, belonging to the order Orthoptera, closely related to the long-horned grasshoppers (q.v.), and represented in Australia by about 50 species. The musical apparatus of the male cricket consists of a stridulating file on the lower surface of the wing-covers, whose rapid vibration causes the edge of one cover to rasp the file of the other.

The Black Cricket (*Gryllus commodus*) is the commonest and most widely distributed species in Australia. Almost black, about an inch in length, the male makes a very distinctive chirruping noise. It is especially prevalent in the vicinity of water, and sometimes damages vines by biting through the stem of a bunch of grapes.

The Mole-cricket (*Gryllotalpa coarctata*), though seldom seen, is frequently heard; it is of a dingy yellowish-brown colour, with powerful front-legs adapted for burrowing, and lives during the day underground, or beneath stones or logs. When alarmed, it ejects an offensive black liquid from its mouth. It nibbles the roots of fruit-trees, and sometimes eats large holes in turnips and potatoes.

The Cylindrical Cricket (*Cylindracheta Kochii*), though seldom seen, occurs in many parts of Australia; it seriously injures the roots of fruit-trees, and is destructive to greenhouse plants, the body being specially adapted for burrowing in plant-stems; while the excavating legs are at work, the middle and hind-legs are closely packed against the abdomen.

Many Australian crickets of the genera *Gryllacris*, *Paragryllacris*, and *Eonius* (belonging to the family Phasgonuridae, the long-horned grasshoppers or tree crickets) are carnivorous. They hide in crevices in trees, or in tunnels made by wood-boring insects, especially in the flowering-stems of grass-trees (*Xanthorrhoea*); one species in north-western Australia makes an underground chamber, the mouth of which it

covers with glutinous threads. They feed at night and, being armed with powerful jaws, can inflict rather severe bites. In the female the ovipositor is about the length of the body, and in both sexes the antennae are much longer. The domestic 'cricket on the hearth' is an introduced cosmopolitan species, *Gryllus domesticus*. See ORTHOPTERA. A.M.L.

Crocodiles, vernacular name of reptiles of the family Crocodilidae, which contains the largest living reptile, the estuarine or salt-water crocodile (*Crocodilus porosus*). Its average length is about 18 feet; but one killed at Barisal in Bengal is said to have been 33 feet long, and J. D. Ogilby quotes a measurement of 32 feet for one shot in the Pioneer River in Queensland. This species is found from India and southern China through Malaysia and the northern coasts of Australia and Papua to the Fiji Islands, both in estuaries and in the upper (freshwater) channels, and occasionally far out at sea; a specimen shot in the Mary River (Queensland) represents its most southerly range. Fossil remains of a larger species have been found near Brisbane and on the Darling Downs. The freshwater crocodile (*Crocodilus johnstoni*), which is only known to occur in northern Queensland and the Northern Territory, grows to about seven feet; it has a more slender snout, and its head is not so rough above as that of the coastal species; the plates on the neck are also different, the series being almost continuous with the other enlarged dorsal plates. It is also comparatively harmless, and feeds principally on fish. As the aborigines put it, the sea-going crocodile is 'cheeky fellow' and would 'round you up,' but the freshwater crocodiles in the land-locked pools are 'frightened fellow,' and their eggs can be stolen with impunity.

The entire body of a crocodile is clothed with scales, the back being protected with bony plates. The elongated mouth is armed with conical teeth on each side of both upper and lower jaws. In the large (sea-going) species there are usually 18 upper and 15 lower teeth on each side; in the freshwater species there may be as many as 20 upper and 17 lower. There are five digits on each fore-limb and four on each hind-limb, the latter being largely webbed. The tail is long and very muscular.

A curious adaption to aquatic life may be seen in the nostrils; the external openings are on the tip of the snout, and the air-passages are prolonged to the back of the lengthy mouth. A crocodile is thus able to hold and drown its prey under water, itself being able to breathe meanwhile so long as the snout is above the surface. Crocodiles will devour almost any animal they can secure, including young cattle, marsupials, reptiles, water-fowl, and occasionally human beings. When motionless, and lying partly under water, they resemble floating logs, and are thus able to approach unalert prey. They have been known to travel a considerable distance overland to a neighbouring stream. Although usually silent, there is evidence that they can emit a hoarse bellow which has been compared with that of an angry bull. In captivity a specimen has been known to stay under water without breathing for 20 minutes.

The name 'alligator,' often applied to Australian crocodiles, is quite incorrect. True alligators are only to be found in the southern States of North America, and in China. In our crocodiles the fourth tooth on each side of the lower jaw is much enlarged, and fits into a notch in the upper jaw, being thus plainly visible when the mouth is closed. In alligators a similar tooth fits into a pit within the border of the upper jaw; the typical alligator, moreover, has a more rounded head, and is more sluggish than the voracious crocodile with its pointed snout.

Crocodiles are oviparous. In the coastal species the number of eggs varies from 20 to 80; they are white, varying considerably in dimensions, the average being about the size of those of a duck, but more elongated. J. MacGillivray gives the following description of a nest on the banks of the Claudie River, at Lloyd's Bay in northern Queensland:—'A crocodile's nest was noted on the right bank, in the mangrove portion, and we landed to examine it. The mangroves were small, the bank about 18 inches above high-tide mark, and the nest 8 feet in from the water's edge. It had a base diameter of about 4½ feet, and 2 feet across the top; it was 3 feet high, composed of decaying vegetation and sand. Uncovering it, the eggs, 43 in number, were found within a foot of the top, all in a heap. A piece of stick was laid across the middle of the eggs —whether by accident or design it is hard to say; but the blacks aver that it is always so.' Newly-hatched specimens are very lively at times, and snap in a vicious manner. They are about ten inches in length. Up to the present, little or no economic use has been made of the skins of either of our Australian crocodiles. H.A.L.

Crook. WILLIAM PASCOE (1775-1846), born at Dartmouth in Devon on 29 April 1775, and during his youth employed in domestic service and tin-working, was accepted by the London Missionary Society (then known as 'The Missionary Society') and sent with a mission party destined for Tahiti, Tonga, and the Marquesas group, leaving England on 10 August 1796. Despite the hostility of the natives, which drove his companions to Australia, Crook worked on in the Marquesas until in 1799 he was recalled to England. Still desiring a missionary career, he was in April 1803 despatched by the Society (which the then colonial secretary, Lord Hobart, seems to have confused with the Society for the Propagation of the Gospel) to take up mission work in the projected settlement under Collins at Port Phillip; that being abandoned, he came on in November to Port Jackson, and was employed as a teacher in the school at Parramatta, with liberty to preach once a fortnight at Ryde and Castle Hill. King next sent him as storekeeper for Paterson's abortive attempt to settle on the Tamar, but cancelled the appointment when the expedition proved a failure, and allowed him to resume his teaching, so that he was able to open a day and boarding-school at Parramatta. During the rule of Bligh's opponents he was employed by them in lieu of Henry Fulton to conduct divine service and baptize; he therefore moved to Sydney, and opened a school at the corner of Hunter- and Bligh-streets—the first boarding-school in Sydney. Reverting to private life on Macquarie's arrival, he on 27 August 1810 joined other missionaries who had been driven from the islands in founding a Congregational Church for Australia, and at once was rebuked by Macquarie at Marsden's instigation for administering the Lord's Supper while an unlicensed and unordained clergyman. At the end of 1815 Crook (on Marsden's recommendation) was appointed by the London Missionary Society to Moorea (and later t Tahiti) in the Society Islands, where he did missionary and medical work for 15 years; on his return to

Sydney (at the end of 1830) he resumed both his teaching and his pastoral work, and after a while built a little church at Watson's Bay. By the time this was finished, however, in 1841, Crook's health had given way; he was forced to leave Sydney and reside with his son in Melbourne, and died there on 14 June 1846.

Crook's controversy with Marsden is of some importance, and must be elucidated. In 1796 the young missionaries, Crook among them, had been solemnly set apart for the work, and he and his colleagues seem to have regarded this as a form of ordination; it is not at all certain that the Society took this view. When in 1810 Crook and four others organized the first Congregational Church in Australia, it was decided to administer the Lord's Supper, and Crook was chosen to preside. He was already out of favour with the authorities for having during the Bligh mutiny acted as chaplain and performed functions only permissible to a priest; Marsden therefore took the opportunity of attacking him for having administered the sacred rite without ordination. As Marsden claimed to be the colonial representative of the London Missionary Society, he was in a strong position as regarded Crook, and Macquarie was bound to support him—the more so because the governor was already attempting to bind Marsden himself down to a stricter observance of Anglican rites. F.V.P.

Crotalaria, a large genus of the family Leguminosae, consisting of herbs or shrubs, widely distributed over tropical regions. The flowers are yellow or blue, in terminal sprays; pod swollen; leaves entire or divided into 3 leaflets. Several species are suspected of causing disease in stock that eat their legumes. This disease is known as 'nenta' in South Africa, and 'loco-disease' in the western United States; it is similar to, if not identical with, the Australian 'pea-eating disease.' *C. juncea,* a northern Australian species, is an erect annual with large yellow flowers. It extends to India, where it is known as 'Sunn hemp,' and is cultivated for the valuable fibre yielded by its inner bark.

Croton, a large, mainly tropical genus of the family Euphorbiaceae, consisting of trees, shrubs, and herbs, usually clothed with star-like hairs. Eleven indigenous species extend through New South Wales to Queensland and northern Australia. The flowers are usually dull; fruit a capsule. *C. Verreauxii* (Native Cascarilla) is a small tree with drooping flower-spikes, the flowers fringed with long woolly hairs. It has a yellowish close-grained timber. *C. phebalioides* is a tree of 40-50 feet, with pendulous branches which, together with the under-sides of the leaves, have a silvery coating of scales. The bark contains an agreeable aromatic bitter; the timber is close-grained and tough, but liable to warp and split in seasoning. *C. insularis* (Queensland Cascarilla, the 'warrel' of the aborigines) has a tough yellow wood, and yields a dye.

Crowfoot. See BUTTERCUP and GERANIUM.

Crows, perching birds of rather large size and black plumage, belonging to the genus *Corvus* and family Corvidae. To the systematic ornithologist the Australian crows are still a puzzle; though all authors agree that three distinct species are found in the continent, no two agree as to the distinguishing features, or as to the range enjoyed by each of the two larger forms. In spite of this, most authors distinguish one of them as the Australian raven, and have placed it in a different genus (*Corone*). The third species, the Small-billed Crow (*Corvus bennetti*), may be at once distinguished by its smaller size. It is an inhabitant of the inland districts of southern and western Australia, and in habits does not appear to differ from its larger relatives. The supposed distinctions between the Crow (*C. cecilae*) and the Raven (*C. coronoides*) are that the former has black body-feathers, snow-white at the base, and hazel eyes; the latter has body-feathers black throughout or dusky at the base, eyes white in the adult though hazel in the young, and some of the throat-feathers elongate and pointed. The latter appears to have a more southerly range than the former, and to be the only species found in Tasmania. All are known to bushmen merely as crows.

They are wary birds, uttering a melancholy, harsh caw which, though one of the characteristic sounds of the bush, seems rather to intensify than to break, its solitude. Crows are more or less sociable, assembling in small scattered companies, or in large numbers when a dead carcase, or a field of newly sown corn, offers them an ample repast. Insects, however, are their staple food, and they devour quantities of grasshoppers, beetles, and caterpillars. They are also partial to fruit, and sometimes make raids on orchards; but their worst sin is that of plucking out the eyes of sick sheep and lambs (some authorities consider that the raven alone is guilty of this last crime). Being thus omnivorous, it becomes a difficult matter to balance the evil they do against their undoubtedly beneficial activities, so as to decide whether their destruction is or is not desirable. Few men on the land give them the benefit of the doubt; but their intelligence, or instinctive cunning, makes their destruction no easy matter, and they are still universally distributed. Owing to the prevalence of the blow-fly pest on sheep in recent years, the value of their scavenging work in removing possible breeding-places for the fly—as well as their wholesale destruction of fly-maggots—has gained much greater recognition, and on many sheep-stations they now enjoy protection. On the other hand they have become very fond of the fruit of the prickly pear (q.v.), and are an important agent in introducing the seed to new districts; hence in prickly-pear areas their destruction is strongly advocated. Crows build large nests of sticks in the tops of trees, and lay three or four dull green eggs, blotched and spotted with brown. W.B.A.

Crowther, WILLIAM LODEWYK (1817-1885), born at Haarlem in Holland on 15 April 1817 and brought by his parents to Tasmania in 1824, was educated at Longford and trained for the medical profession by his father, who was a surgeon. During his boyhood he diligently collected Tasmanian animals—both live specimens and skins—and in 1839 took his collections to England, sold them (the live animals to the Zoological Society), and with the proceeds maintained himself while attending St. Thomas's hospital for medical training (M.D., 1841; F.R.C.S., 1874). In 1842 he returned to Tasmania and took over his father's practice in Hobart. From 1850 to 1870 he interested himself in the whaling industry, and owned a small fleet of whalers which added much to the prosperity of the port. In 1866 he was elected by Hobart to the legislative assembly, but resigned after two months' attendance; in March 1869 the Hobart division elected him to the legislative council, and he retained the seat to the day of his death. From July 1876 to August 1877

he was a member of the Reibey ministry, and from December 1878 to October 1879 was himself premier, but on neither occasion administered a department. He died at Hobart on 12 April 1885.

Crustacea, a large and important class of animals comprising crabs, lobsters, crayfishes, prawns, shrimps, sandhoppers, barnacles, water-fleas, and woodlice. The orders particularly discussed in these volumes belong to the sub-classes Entomostraca (see WATER-FLEAS) and Malacostraca: in the latter sub-class are included Isopoda (see WOODLICE), Amphipoda (see SANDHOPPERS), and Decapoda, the last order being again divided into Macrura (see PRAWNS AND SHRIMPS and CRAYFISHES), Anomura (see HERMIT CRABS), and Brachyura (see CRABS). Other crustacean orders either do not occur in Australia or have no specially Australian forms.

Cryptocarya, a genus of the family Lauraceae, consisting of trees or tall shrubs, chiefly Asiatic, with a few species found in South Africa and South America. Sixteen species are indigenous to eastern Australia. *C. obovata* is one of several trees known as 'she-beech,' a tree up to 100 feet, extending from New South Wales into Queensland, having aromatic leaves and yielding useful timber. *C. glaucescens* (Brown Beech, Black Sassafras), is a tree of 40 feet confined to coastal New South Wales and Queensland. *C. microneura* (Murrogun), also found in the coastal brushes, has a hard, close-grained wood, fragrantly aromatic. *C. australis* (Grey Sassafras, Moreton Bay Laurel), has a light, useful timber with an odour objectionable to insects. The bark has a bitter taste, due to the presence of an alkaloid.

Cuckoos, birds with long tails, and feet with two toes before and two behind (as in parrots), belonging to the order Cuculiformes. Birds of this order are found throughout the world, but are specially numerous in the Australian region. Fourteen species, belonging to four families, are found in Australia and Tasmania, 11 of which are true cuckoos (family Cuculidae). All those found in southern Australia and Tasmania are summer migrants, but in northern Australia some species are to be found at all seasons. Australian cuckoos, like the well-known European cuckoo, deposit their eggs in the nests of smaller birds, usually extracting an egg from the nest in which their own egg is placed. As a rule each species of cuckoo is parasitic on a small number of other species of birds, to the eggs of which its own bear a fairly close resemblance. For example, the eggs of the Pallid Cuckoo (*Cuculus pallidus*), which are pale buffish-pink, are generally placed in nests of the larger honey-eaters—such as wattle-birds and miners—which lay eggs of a similar colour. They are, however, not uncommonly found in the nests of other birds—e.g. wagtails or reed-warblers—to the eggs of which they bear no resemblance. In such cases it is almost certain that the cuckoo has been unable to find a honey-eater's nest at the right stage to receive her egg.

The young cuckoo, soon after hatching and before its eyes are open, manages to get the eggs or young of the rightful owner of the nest one after another on to its back. Each is then carried up to the edge and thrown out; thereafter the young cuckoo (which has a voracious appetite) receives all the attention of its foster-parents. These continue to feed it after it leaves the nest, when it is much larger than themselves; sometimes it also receives food from birds other than its foster-parents.

Almost all cuckoos utter loud and constantly repeated calls or shrill whistles, which in the breeding-season are to be heard all day and frequently at night as well, so that their constant repetition becomes exceedingly wearisome. The pallid cuckoo is the commonest species throughout southern Australia, its call consisting of a succession of notes in an ascending scale, the last being repeated several times. The Fan-tailed Cuckoo (*Cacomantis flabelliformis*), a rather smaller species, also common, utters a plaintive, trilling note. The four other comparatively large cuckoos are rarer, and are chiefly found in the north.

The five small bronze cuckoos resemble one another very much in appearance, but their notes are quite distinctive. The common Bronze Cuckoo (*Lamprococcyx plagosus*) and three of

Bronze Cuckoo.

its allies are exceptions to the rule about eggs already mentioned; they lay olive-brown eggs, and generally place them in the nests of tits or wrens which lay white eggs, more or less speckled. The nests of these birds being domed, the eggs are almost in darkness, and coloration is probably of less importance. Numerous instances are on record, however, of birds deserting their nests when a bronze cuckoo's egg has been placed in it; and sometimes the birds add to the lining of their nests, so that the cuckoo's egg is covered over. The Narrow-billed Bronze Cuckoo (*Chalcites basalis*), though almost indistinguishable from its relatives in plumage, chooses open nests in which to lay its white, speckled eggs.

Cuckoos play an important economic role, since their favourite diet is hairy caterpillars, which few other birds will touch. We must set against this, however, the destruction of many other insectivorous birds that results from their parasitic habits.

The Australian Koel or Coo-ee-bird (*Eudynamis orientalis*), our sole representative of the koel family (Eudynamidae), is common during

the summer in northern and eastern Australia. Its call is loud and mellow, not unlike a coo-ee; it has even been suggested that the aboriginal cry is an imitation of this bird's note. In the koel the sexes are quite distinct in colouring, the male being glossy black and the female brown, spotted with white. The egg is usually placed in the nest of a friar-bird, miner, or oriole.

The remarkable Channelbill (*Scythrops novae-*

Channelbill.

hollandiae), the sole member of its genus and of the family Scythropidae, visits northern Australia in the summer from the Malay Archipelago. It is a large grey bird, with a bill resembling that of a toucan and a patch of bare red skin surrounding the eye. Its note is a loud scream, and it is often called rainbird, as it is supposed to be specially noisy before rain. It places its eggs in the nests of crows or magpies.

The Coucal or Swamp Pheasant (*Centropus*

Swamp Pheasant.

phasianinus) is the only Australian representative of the family Centropodidae, members of which occur throughout the warmer parts of the old world. The coucal is found throughout northern Australia wherever there are swamps with plenty of tussocky grasses. The name 'swamp pheasant' by which it is commonly known, is due to its strong resemblance to a hen pheasant; but the structure of the feet at once indicates its real affinities. The coucal is the only Australian cuckoo which makes a nest and rears its own young. The nest is a large, domed structure in a grass tussock, with a hole at each side; the head and tail of the bird project from these holes when it is sitting; the eggs, 3 to 5 in number, are dirty white. The swamp pheasant runs rapidly on the ground, and frequently clambers into a bush or low tree, whence it utters a deep note, constantly repeated, resembling the croak of a frog. W.B.A.

Cuckoo-shrikes and Caterpillar-eaters, perching birds, usually of rather large size, belonging to the family Campephagidae. This family is found in Africa, tropical Asia, the Malay Archipelago, Australia, and some of the Pacific islands, but is most abundant in the Australian region. In Australia and Tasmania eight species occur. No satisfactory popular names have been invented for any of the species; they are known to ornithologists by the names given at the head of the article, though these can hardly be called vernacular.

These birds are as a rule strictly arboreal in habits, and feed largely on beetles, caterpillars, aphides, and other plant-infesting Hemiptera. They often unite in small parties; many have a curious habit of folding and unfolding the wings several times after alighting on a branch, as if the proper adjustment was a matter of some difficulty. Their nests are (considering the size of the birds) extremely small, shallow structures, composed of twigs or wiry grasses fastened together with cobwebs, and usually placed in the forks of horizontal branches. Some species lay only a single egg, others two or three.

Blue Jay.

Throughout the greater part of Australia the most familiar member of the family is the Black-faced Cuckoo-shrike (*Graucalus novaehollandiae*), better known as 'blue jay' or 'blue pigeon.' It is a rather large bird, blue-grey with a black mask on the face, and frequently utters curious, rather raucous, notes as it flies from tree to tree. The Little Cuckoo-shrike (*G. robustus*) is a shyer and smaller species, with less black on the face, fairly common in south-eastern Australia.

The Ground Cuckoo-shrike (*Pteropodocys maxima*), larger and paler than the blue jay,

Ground Cuckoo-shrike.

is almost confined to the inland districts. As its name implies, it is much less arboreal than its relatives and seeks much of its food on the ground.

The White-shouldered Caterpillar-eater (*Campephaga tricolor*)—known as 'spink' in the Riverina—is a summer migrant throughout the greater part of Australia, though in the north it appears to be occasionally resident. The hen-bird is brown with pale underparts; the cock-bird resembles her in the winter, but during the breeding-season assumes a conspicuous black-and-white plumage. He is the best songster of the family, uttering a rapid series of melodious notes, usually when flying from one tree to another. The Pied Caterpillar-eater (*C. leucomela*) is not so common, and is found only in the north and east of the continent. The sexes in this species are more alike, somewhat resembling the male of the commoner bird, but with

White-shouldered Caterpillar-eater.

a patch of orange-buff beneath the tail. The female has, in addition, a series of narrow black bars across her breast. W.B.A.

Cudrania, a genus of the family Urticaceae, consisting of a single species, which ranges from New South Wales into Queensland, and extends to East Africa, India, and Japan. *C. javanensis* (Fustic or Cockspur thorn, the former name referring to a yellowish-brown dye that is made from the heart-wood) is a shrubby climber, armed with stout axillary spines which represent abortive flower-stems.

Cullen, Sir William Portus, born near Jamberoo in Illawarra on 28 May 1855 and educated at the university of Sydney (B.A., 1880; M.A., 1882; LL.B., 1885; LL.D., 1887), was called to the bar in 1883 and soon took high rank on the equity side. In July 1891 he entered politics as member for Camden, his fellow-member being John Kidd; when in 1894 single-member constituencies were created, and Kidd won Camden, Cullen was appointed (on 8 August 1895) to the legislative council. In parliament he was no partisan, and has been described as 'one of those welcome speakers who never rise until they have something to say and always sit down when they have said it.' Outside his profession he was probably most interested in the university, of whose senate he was elected a fellow in 1896, made vice-chancellor in 1908-10, and chancellor in 1914. As far back as 1896 he introduced into council a bill for university reform, including the reforms which were eventually carried in 1912—a limited term of office for senators, and election of them by postal vote. On the death of Sir F. Darley early in 1910 Cullen was (on 28 January) made chief justice of New South Wales, with a dormant commission as administrator of the government during any absence of the governor; this, however, was superseded on 30 March 1910 by a definite appointment to the post of lieutenant-governor. He resigned the chief-justiceship on 28 January 1925. (Kt. Bach., 1911; K.C.M.G., 1912.)

Cunjevoi (1) Popular name of *Colocasia macrorrhiza*, the well-known Green Arum or Spoon Lily (family Araceae), which usually grows in dense masses on river-banks, or in the moister and shadier parts of brush forests, in eastern and tropical Australia. It is also widespread over tropical Asia and Oceania. The spathe is green and spoon-shaped; the leaves spear-shaped, often 2 feet long. The plant is commonly cultivated in suburban gardens. The aborigines use the young bulbs for food, after a careful preparation; first the bulbs are scraped, divided, and put under hot ashes for about half an hour, then pounded between two stones (a large one, *wallarie*, and a small one, *kondola*); all pieces that look watery when broken are then thrown away, and the rest, made into lumps by strokes of the *kondola*, are again put into the fire. This operation is repeated 8 or 10 times, until the lumps are consolidated into a single greenish-grey-coloured mass, the *hakkin*; when this begins to harden it is fit for use. The plant is very acrid when fresh; but heating or drying renders the roots innocuous. The juice of the leaves is used as an antidote to the sting of the Giant Nettle-tree (*Laportea gigas*).

(2) Popular name of a polyp (*Cynthia praeputialis*) common on the Australian coasts. It is often used as bait for fishing.

Cunningham, ALLAN (1791-1839), born at Wimbledon on 13 July 1791, educated at Putney and trained for the law by a Lincoln's Inn conveyancer, found those studies uncongenial and became assistant to Aiton, the manager of Kew Gardens. Aiton recommended him to Banks as a collector, and Banks in 1814 obtained his appointment to collect plants in Brazil, where he spent two years; in August 1816, however, he was ordered to proceed to New South Wales, and reached Port Jackson on 20 December 1816. He was almost at once attached to Oxley's expedition of 1817 (14 April to 29 August), and on return was transferred to P. P. King's survey of the Australian coasts (see EXPLORATION BY SEA), which occupied his time from 22 December 1817 to 25 April 1822. His notes on the botanical results of the survey occupy nearly 40 pages of King's *Narrative of a Survey*, and were thought important enough to be published separately in a German translation. In August 1822 he resumed his botanical researches within the colony, visiting Illawarra, the Blue Mountains and the Bathurst-Mudgee district. In 1823 he began a series of explorations (described under EXPLORATION BY LAND), during which he discovered Pandora's Pass across the Liverpool Range, connecting the Mudgee district with Liverpool Plains (1823), explored those plains (1825), discovered the Darling Downs (1827), and found a way to them from the shores of Moreton Bay (1828). For none of these discoveries did he receive any reward beyond formal thanks. Four months of 1826 he spent botanizing in New Zealand round the Bay of Islands, and in 1830 visited Norfolk Island. By this time he was due for leave; he sailed for England on 25 February 1831, arrived there in July, and settled down for four years at Kew to arrange and name his specimens.

On 31 December 1831 Charles Fraser, the colonial botanist, died, and his position was at once offered to Cunningham, who refused it but suggested the appointment of his brother Richard (q.v.). When Richard died in 1835, the offer to Allan was renewed, and on this occasion accepted. He reached Sydney on 12 February 1837, but found that his duties included too much actual gardening (the government officials having formed the habit of procuring their supply of vegetables from the botanic garden), and other uncongenial work such as the construction of paths along the harbour side. At the end of 1837, therefore, he resigned his position. Gipps, arriving in February 1838, was anxious to retain him in the service, and appointed a committee (including Alexander and George Macleay, Deas Thomson, P. P. King and Charles Sturt) to negotiate with him, at the same time abolishing the 'cabbage-garden' practice. Cunningham thereupon demanded the position of government botanist with a salary of £450 and no responsibility for the botanic garden, travelling expenses for himself and party on trips to out-stations, Tasmania, and New Zealand, and carte blanche as to the disposal of his time. The committee favoured all these demands except the last, which they feared might prove a dangerous precedent—their alternative proposal was six months' leave in every year to prosecute explorations. Gipps, however, calculated that the extra expenditure would amount to at least £850 a year, and declined to authorize it; so the negotiations fell through, and Cunningham on 15 April 1838 left Sydney for New Zealand, where he botanized for six months. For some time his health had been giving way, and he returned from New Zealand 'in a deplorable state of health' to die on 27 June 1839 in a cottage in the Sydney botanic garden. He was buried in the old Sydney cemetery (now the site of the central railway station), and an obelisk was erected to his memory in the botanic garden. When in 1901 the cemetery grounds were resumed for railway purposes, his remains were placed in a casket within the obelisk.

Cunningham, RICHARD (1793-1835), brother of Allan Cunningham, was born at Wimbledon on 12 February 1793 and educated at Putney, following his brother as assistant to Aiton at Kensington and Kew from 1808 to 1832. Charles Fraser, colonial botanist of New South Wales died at the end of 1831, and the position was offered first to Allan Cunningham and then by his advice, and on the recommendation of Robert Brown (q.v.), to Richard. He reached Sydney on 5 January 1833, bringing out with him a selection of vines from France and Spain for establishing the grape-growing industry; these he planted in the botanic garden, which he soon remodelled and improved. In 1833 and 1834 he visited the Bay of Islands in New Zealand (which was then nominally under New South Wales jurisdiction) to collect plants and superintend the felling of kauri pines. In March 1835 he was attached to Mitchell's expedition for the exploitation of Sturt's discoveries on the Darling. No bushman, yet eager to go far afield in search of new plants, he had to be warned on several occasions by Mitchell against losing himself. On 17 April he left the main body to rejoin Mitchell, who had galloped ahead to find a waterhole for the night's camp; failing, however, to notice that the leader had turned sharply northward, he went straight on into dry country, and was never seen again, though his tracks were discovered and followed backwards and forwards, and Mitchell spared no effort to rescue him. His fatal lack of bushcraft doomed him. He was rarely out of sight of the bluegums that grew in neighbouring creek-beds, yet never approached them to look

for water; he was usually within a mile or so of the expedition's tracks (and they were deep and unmistakable), yet never followed them; and, when on the 19th he actually found a note of Mitchell's fixed in a stick in the middle of a small plain, telling him that the camp lay NE., he almost immediately veered to the north-west and then travelled for a day or more due north to and along the Bogan. The dead body of his horse was found, and his whip, and some straps and papers; on the 29th his tracks were noticed near the river, and on 5 May a piece of his coat and fragments of a map were found near a deserted native camp. It was discovered some months later that he had fallen in with a party of natives, who at first befriended him but took alarm at his restlessness and killed him.

Cupuliferae, a family almost exclusively found in the northern hemisphere, consisting of trees or shrubs with unisexual flowers, the males in catkins, the females few or solitary and surrounded by a series of scale-like bracts. The genus *Nothofagus* comprises three species which are endemic in Australia. *N. Gunnii* is a dense, bushy plant confined to several mountain summits in Tasmania, where it often covers a considerable area with an almost impenetrable growth 5-8 feet high. *N. Cunninghamii* (Myrtle or Evergreen Beech), which is confined to Tasmania and Victoria, at low elevations attains a tall forest growth, but at the 4000-ft. level is reduced to a shrub. *Cyttaria Gunnii,* an edible fungus, is parasitic on this tree. Its timber is prized for sash and door work and light joinery. *N. Moorei* is the 'Negro-head' Beech, a handsome tree up to 150 feet, found in the rich brush forests along the northern rivers of New South Wales.

Currency. In the early years of the settlement at Port Jackson barter was the recognized medium of exchange, and rum, corn and wheat the principal articles used as currency. The scarcity of coin is not surprising; for 26 years after George III ascended the throne practically no coins were struck in England, and in 1787 only £55,489 worth of shillings and sixpences were coined. To remedy the deficiency, Spanish dollars and half dollars were in 1797 countermarked with the king's head and made current. Rum was from the first the great circulating medium. A labourer's wages were stated as so many gallons of rum; rewards for the apprehension of escaped convicts were given in rum; for four gallons of rum a wife was purchased from her husband. The effects of using such an unstable article as a circulating medium were very demoralizing. Bligh declared that 'a sawyer will cut one hundred feet of Timber for a Bottle of Spirits—value two shillings and sixpence—which he drinks in a few hours; when for the same labour he would charge two Bushels of Wheat, which would furnish Bread for him for two Months.' Another pernicious element was the varying and exorbitant price charged for rum. The price was continually varying and in 1792 ranged from 5s. to 20s. per gallon. When King arrived, he found that rum which cost the importers from seven to ten shillings per gallon was being retailed at £2. Spirits were bartered by everyone; even Richard Johnson, the chaplain, paid partly in spirits the cost of erection of his 'wattle and dab' church in 1793, and the price of admission to the first theatre in Sydney could be paid in 'money, flour, meat or spirits according to the market price.' The most historic case of the use of rum as currency is connected with the erection of the hospital in Sydney in Macquarie's time, the contractors for which were paid with a monopoly of the spirit traffic for four years. Another form of currency was the store-receipts issued by the commissary for wheat and other articles supplied to the government stores; these were convertible into bills on the London treasury at par, but usually passed from hand to hand and acted as a paper currency.

The first record of a currency regulation appeared in a proclamation issued by Governor King on 19 November 1800:——

Whereas Representations of the Want of small money experienced here has Induced His Majesty to take into His Gracious Consideration the Immediate relief from this great Inconvenience to all Classes of His Subjects in this Colony, a Quantity of Copper Coin has been received in His Majesty's Armed Vessel Porpoise and Royal Admiral, and will be circulated by being paid for Grain and Animal Food supplied His Majesty's Stores.

These are therefore to give notice that a Copper Coin, weighing One English ounce, and stamped with the profile of His Majesty on the one side, and of Britannia on the other, will be issued as above, at the rate of Two pence for each Copper; and that the same shall pass Current in the Colony, and is to circulate at the Aforesaid Rate of Two Pence.

And that no one may plead Ignorance of the Rate or Legality of this or any other of the coins circulating in this Colony, of which it does not appear that any regular Proclamation has ever collectively been issued, I have judged it most expedient herewith to publish the following Table of all the Specie legally circulating in this Colony, with the Rates Affixed to each, at which they shall be considered and be a legal tender in all payments or transactions in this Colony.

	£	s.	d.		£	s.	d.
A guinea ...	1	2	0	A rupee	0	2	6
A half-Johanna	2	0	0	A Dutch guilder	0	2	0
A gold mohur	1	17	6	An English shilling ..	0	1	8
A Spanish dollar	0	5	0	A copper coin of 1 oz. ...	0	0	2
A Johanna ..	4	0	0	Ditto., ½ oz...	0	0	1
A ducat	0	9	6	Ditto, ¼ oz...	0	0	0½
A pagoda ...	0	8	0				

When a sufficient quantity of Copper Coin is received in the Colony, of which notice will be given, no private *Notes* or *Cards* will be allowed to Circulate.

This Supply of Copper having been sent to relieve the Inconvenience of persons requiring to make small payments, no persons are to Collect the same for the purpose of making large payments, nor shall it be deemed a legal tender to offer the same in payment for any sum exceeding five pounds.

And it is hereby declared that the Exportation or Importation, except from His Majesty's Treasury, of any sum exceeding five pounds of the above-named copper coin, shall be punished by fine of treble the value, and forfeiture of the sum exported or imported.

Only £550 worth of copper coin was brought out in the *Porpoise.* As C. P. Hyman (*Coins, Coinages and Currency of Australasia*) points out, by this proclamation the local values of the various coins were deliberately enhanced in order to 'keep the money in the country.' Thus the Johanna was a Portuguese coin worth outside New South Wales about £3 12s., mohurs in India passed for about £1 12s., and rupees

for 2s. 3d.; the copper coins, it will be noticed, are actually doubled in value. Yet Collins laments that the copper coinage was not distinctively marked 'to prevent its being taken out of the Colony.' Copper coins, however, were not scarce by 1810, for we find in that year a government proclamation threatening that persons neglecting to consolidate their store receipts within the time ordained 'subject themselves to be paid in Copper Coin.' In November 1816 Macquarie was advised to call in the copper coin, which had depreciated in value, and reissue it at a more suitable value in sterling. On 7 December, therefore, he proclaimed that all copper coins of 1800 or previous years would be accepted up to 1 January 1817 at 1½d. for each penny piece, but after that date would be worth only the face value.

Paper Currency.—The store receipts referred to above proved so useful as a paper currency that the government found a difficulty in collecting them to be exchanged for bills. In 1815 Macquarie deemed it desirable, in view of the lack of specie, to reintroduce them. A government order of 25 March read:—

> In order to obviate the inconveniences that are likely to result to the Public from the want of a Sufficient Quantity of *Specie* belonging to Government, His Excellency the Governor deems it advisable to resort again to the System, formerly pursued in this Colony, of issuing *Store Receipts* for all Purchases made on account of the Crown, not only at Headquarters, but also at all the out and Subordinate Settlements, dependent on this Territory.
>
> The Governor accordingly hereby orders and directs that, from and after the 24th Day of the ensuing Month of April, all Purchases of whatever kind or Description, made on account of Government, shall be paid for in *Dollars* or in *Store Receipts*. . . .
>
> These Store Receipts are to be brought into the Deputy Commissary General at Head Quarters for Consolidation, regularly at the End of every two Months, and all Persons possessing them are strictly enjoined to be punctual in doing so. . . .

In 1819 the system was discontinued, but revived again in the following year, and continued in use for some years.

The dearth of small coin at Port Jackson and in Van Diemen's Land led merchants and traders to issue promissory notes for amounts as low as threepence; these became known as 'currency,' as distinguished from 'sterling' specie or government money. For some years they were readily absorbed by the community, but in course of time were depreciated by abuse; forgeries were frequent, and the consequences arising from lack of control of issue were well summarized by W. C. Wentworth in his *Description of the Colony of New South Wales* (1819). The whole burden of providing a circulating medium, he says, fell on the colonists, many of whom promptly became bankers and issued promissory notes; this 'colonial currency' was soon worth only half its face value in government money, and yet the issuers were compelled by law to redeem it at par on presentation. Consequently the most solvent traders withdrew their notes, and with government money bought up for trading purposes the depreciated notes of their weaker fellows; lacking sound support, the notes depreciated still further—and yet had to be used for the lack of any other medium. The public, therefore, 'thus affixed a kind of nominal value to that which is in reality worth nothing.'

In June 1810 it was ordained that all promissory notes for £5 or less must be printed, hand-written notes having been forged wholesale. They must be drawn for the payment of a certain sum sterling, and non-payment of the amount within three days after demand rendered the defaulter liable to penalties. In November 1816 it was deemed expedient to authorize the circulation of sterling money or 'promissory notes for the payment of the same in Sterling Value and Amount only,' and it was declared unlawful for any person to issue or negotiate any promissory note which did not express and declare that the amount thereof was payable in sterling money. In continuation of the policy of eliminating unstable currency a further proclamation was issued on the 25th insisting that all prices quoted for purchases, wages, etc., must be specified in sterling; and on the 29th a meeting of officials, free settlers and traders decided that sterling prices should be two-thirds of the former currency prices, and that contracts and bargains payable in currency should be reduced to sterling by deducting from one-fifth to three-sevenths of their value to represent the existing depreciation. The circulation of promissory notes, however, continued until 1826, when an act prohibited their issue for amounts less than 20 shillings sterling. By this time the Bank of New South Wales was in operation, and the circulating medium had assumed something like stability.

The Spanish Dollar.—In the return issued by King on 19 November 1800 (previously quoted) the Spanish dollar is set down as worth five shillings. This coin played a large part in the currency not alone of New South Wales but of the whole world; and Brisbane on one occasion described it as 'an invaluable coin, which has for centuries been disseminating its benefits over every other portion of the earth—a coin which, from the extension of its circulation over every part of the commercial globe, may justly be defined the money of the world . . . Driven, indeed, from the United Kingdom by her moneys of sterling denomination, it still maintains all its pre-eminence in every one of her Colonies. Confined in its advantages to no faith, kindred, or Government, it has for ages been bestowing sterling benefits on the British and Protestant North American Colonies; on the French and Papal Canadas; on Mahomedan India; and on the whole world.' Its history is therefore worth considering.

For several centuries practically the whole coinage of the European world and its dependencies came from Mexico, where a mint was established in 1535. From this mint were issued the 'Spanish dollars' or 'pieces of eight' so well known to buccaneers and captors of treasure-ships. The sign $ now used to signify the United States dollar is supposed to derive from the Spanish 'pillar dollar' of eight reals; the curved portion of the sign is a rude 8, and the vertical stroke is a symbol of the Pillars of Hercules, an emblem of the Spanish Empire. Pieces of eight were known by that name until about 1728, after which date they were called dollars—a name originally invented for silver coins of equivalent value minted in a Bohemian valley (*thalers*, from Joachims Thal).

These dollars circulated throughout the world, and the English colonies of North America adopted them as early as 1704 on an equality with English sterling coins; their value, in the 17th century 4s. 6d. each, rose by 1782 to 7s. 6d. in most ports and even 8s. in New York. Between 1790 and 1812 the Mexican mints

turned out 24 millions of them, but they were so much in demand that New South Wales, whose chief silver coins they were, could not retain them; in 1804 Governor King mournfully wrote:—

> The fallacy of endeavouring to keep Spanish dollars or any sterling coin within the Colony has long been proved, even when the former has been cut into eight or ten parts, as these coins are never seen after they are paid away.

Occasionally, however, there was a windfall of them. In the very year of King's complaint an English whaling vessel attacked a Dutch vessel off Sumba, captured her after a midnight fight (11.30 p.m. to 1.30 a.m.), and brought her into Port Jackson with £20,000 of Spanish dollars aboard. King did not feel justified in handling so huge a financial transaction, and refused to buy the coin, but a good deal of it remained in the colony.

Macquarie was the first governor to hit on a really effective method of preventing the re-exportation of dollars. Having received in November 1812 a consignment of £10,000 worth of dollars by the *Samarang*, on 1 July 1813 he issued a proclamation directing

> that a small Circulating piece of Silver shall be struck out of the centre of every such dollar, which together with the remaining part of every such dollar is intended to be issued and circulated, at the value and under the regulations hereinafter described . . . that each and every small Circular piece of silver, on one side of

HOLEY DOLLAR

Obverse

Reverse

DUMP

> which is impressed with the figure of a Crown, the words 'New South Wales,' above such impression, and the figures 1813 beneath the same, and the other or reverse side thereof are impressed the words 'Fifteen Pence,' and having the Edges thereof Grained, shall be current within the territory for the sum of fifteen pence of lawful Money of the United Kingdom of Great Britain and Ireland, of English value and Currency . . . that every such larger piece of Silver, being the remaining part of every such dollar, on the upper part of one side of which are impressed, at its inner rim, the words 'Five Shillings,' and at the lower part of the said Rim, on the same side is also impressed the figure of a Branch of Laurel, and on the reverse side of which, at the Upper part of the said inner Rim, are impressed the words 'New South Wales,' and at the lower part of the same Rim the figures 1813, the Edges of the said inner Rim being grained on both sides, shall be current within this territory, and every part thereof, for the sum of Five shillings of lawful Money of the United Kingdom of Great Britain and Ireland, of English value and Currency.

This dollar became generally known as the 'holey dollar,' while the smaller piece removed from the centre was called the 'dump.' It was found necessary to engage to receive these coins back again into the treasury, at their current value, at the expiration of every two years in exchange for bills on England. It was anticipated that the issue of these dollars and dumps would correct the currency trouble, but these hopes were not realized. Counterfeits soon appeared, and the Bank of New South Wales in 1821 found it necessary to issue a notice drawing attention to the illegal coins in circulation, which were described as

> Dollars and Dumps which are not Silver; Dollars, having the usual Holes in the Centre, but without the Colonial Stamp on them; Colonial Dollars, from which a portion of Silver has been taken round the Centre, whereby the Hole is made considerably larger; and Dollars that bear a Counterfeit Stamp, intending to imitate the Colonial one surrounding the Hole in the Centre, many of which may be detected by the Figures for the Date of the Year, being transposed from 1813 to 3181.

Up to 1822 it was the practice in New South Wales to express money-values in dollars, and even government notices followed this custom. But in May of that year the directors of the Bank of New South Wales issued a notification that they declined to receive Spanish dollars until a specific value was fixed by the government. They pointed out that the dollar had hitherto circulated at a nominal value of 5s. sterling, which was nearly 17 per cent above its value as bullion; that within the last three months dollars 'to a very alarming amount' had been imported into the colony; and that through such an influx of specie the nominal value could not be maintained unless the government continued to make their sterling payments in a foreign coin, thus rendered a legal tender.

Brisbane, who was an ardent advocate of the Spanish dollar, attempted to place the currency on a sound basis by making the dollar the standard of value in the colony; to effect this, 400,000 dollars were imported and issued at the regulation rate of 5s. in payment for supplies, and notice was given that colonial duties and government quit rents would be received in these coins at the like rate. On 28 July Brisbane further ordered that the holey dollars of 1813 should be exchanged at their rate of issue if tendered for exchange within six weeks; these coins were reissued at the end of the year, and passed current for three-fourths of the Spanish dollar. The results of Brisbane's policy are severely criticized by Robert Chalmers in the book mentioned at the end of this article.

On 4 May 1825 the governor notified that Spanish dollars would be received at an exchange of 4s. 4d. in sterling money in all payments into the colonial fund. In the same year the British government arranged for a supply of British silver, and on 31 December the governor issued a general order fixing the value of Spanish dollars at 4s. 4d. and 'Calcutta or sicca rupees' at 2s. 1d. For the future, also, government accounts were to be made up and stated in sterling. An act passed on 12 July 1826 repealed the 1824 act respecting notes, prohibited the issue of notes of less denomination than 20s., and confirmed the just ordained value of the Spanish dollar. The commissary in New South Wales at first found a difficulty in providing a sufficiency of British coin, but this was met by the importation of £55,000 in British silver. In October 1827 about £7000 of this was in general circulation, £14,000 in the two banks, and the other £33,000 in the military chest. But the British money soon was absorbed into general circulation, and on 24 September 1829 the military chest contained

British silver coin	£12	8	0
British copper coin	701	14	8
Ring dollars, 27,161 at 3s. 3d.	4413	13	3
Spanish dollars, 3432 at 4s. 4d. ..	743	12	0
Rupees, 734 at 2s. 1d.	76	9	2
Dumps, 10,103 at 1s. 1d.	547	4	11

The general order of 16 December 1828 was the first decisive step towards withdrawal of the holey dollars; it stated that 'ring' dollars would be received at the colonial treasury in exchange for bills on the British treasury at 3s. 3d. each, and dumps at 1s. 1d. On 23 November 1829 the traders and shopkeepers of Sydney unanimously resolved to accept the Spanish dollar at 4s. 2d. and the rupee at 1s. 9d. only; and from this date the Spanish dollar gradually disappeared from the currency of New South Wales, although it was retained in Tasmania until an act of the Tasmanian legislature (14 September 1842) decreed that from 1 October of that year foreign coins should cease to circulate legally.

The discovery of gold in 1851, and its consequent output, created a demand for a mint at which it might be coined. There was not sufficient coin in the colony with which to buy the gold produced, and gold dust of over the standard fineness was commonly sold in Sydney for about £3 per oz. A committee of the legislative council recommended that a request should be made for the establishment of a mint in Australia, and a petition to that effect was despatched, dated 19 December 1851. Melbourne, however, protested strongly against the establishment in Sydney of the sole mint for Australia. Formal authority for the establishment of a branch of the royal mint was given by an order in council of 19 August 1853, and designs for the new sovereign and half-sovereign were approved on 18 October 1854. The New South Wales legislature then passed an act (No. 39 of 1854) which provided for a gold coinage at Sydney identical with, and equivalent to, that of the United Kingdom, and followed it up with another (No. 3 of 1855) to regulate the local currency, which is in force in New South Wales at the present day. This second act provided that the gold coin issued from Her Majesty's mint in London and the gold issued from the branch of the royal mint in Sydney, should be the only legal tender for payments within New South Wales, except that silver coin, whether British or Australian, should be legal tender up to 40s. at one time. The Sydney branch was opened on 14 May 1855, and between that date and the end of 1859 coined over five millions worth of sovereigns.

In 1856 the New South Wales legislature asked that the Australian sovereign might be declared a legal tender throughout the Queen's dominions, and after some delay a British act (26 and 27 Vic. C. 74) was passed on 28 July 1863 'to enable Her Majesty to declare gold coins from Her Majesty's branch mint at Sydney, New South Wales, a legal tender for payment and for other purposes relating thereto.' The necessary proclamation was made on 3 February 1866, and a further proclamation (of 10 November) declared the Sydney sovereign and half-sovereign a legal tender for all the British colonies except Canada and Newfoundland. This exclusion was cancelled on 14 May 1868. The Sydney mint was first employed in the issue of imperial bronze coins in 1868, and of imperial silver coins in 1879.

Up to 1851 *Victoria* had no currency history distinct from that of New South Wales. The legislative council of Victoria on 31 July 1852 asked for the establishment of a mint in Melbourne. The proposal remained in abeyance for some years; but by an order in council of 7 August 1869 authority was given for the establishment of a branch mint at Melbourne, to strike gold and other coins, and a proclamation of the same date declared gold coins struck at the Melbourne mint to be legal tender in all places where the London sovereign was a legal tender. The new mint was opened on 12 June 1872.

Peculiar gold pieces were struck in Victoria in 1853. On the obverse of the design are the words 'Port-Phillip, Australia' incused upon a broad rim, which is in relief. The date—1853—is placed under a kangaroo. On the reverse are the words 'Pure Australian Gold,' with the weights in words and numerals of the various pieces struck—¼, ½, 1, or 2 oz. It was intended by the strikers that these pieces should pass current locally at £1, £2, £4, and £8; but by the time the machinery was in working order gold was fetching £4. 4s. an ounce and English sovereigns were plentiful. The enterprise was therefore abandoned. It is probable that only a single set was ever issued in Victoria, but replicas have been made from the original dies for museum purposes.

In 1825 *Tasmania* was erected into a separate colony, and encountered the same trouble with paper currency and the fluctuating values of the Spanish dollar as did the parent State. On 2 September 1835 a local act made the sicca rupee legal tender at 2s.—but this act was disallowed by the home government. The South American dollar (which took the place of the Spanish dollar after the revolt of the Spanish colonies in America) was legalized in 1834 at a value of 4s. 4d.; the banks refused to regard the new coin as legal tender, and an act of 28 November 1838 legalized them, but in 1842 the act 6 Vic. C. 7 demonetized them again, and they gradually disappeared from the currency. Gold coins of the Sydney mint were declared legal tender on 18 October 1854 and those of the Melbourne mint on 7 August 1869. The only other official act affecting the currency of Tasmania was the issue of a proclamation on 11 October 1875, whereby the old British copper coins were demonetized, and British bronze coins were declared a legal tender.

South Australia.—The first reference to South Australian currency is to be found in the colonization commissioner's instructions to Colonel Light, dated March 1836—'You will pay the wages of the labourers under your command by orders on the storekeeper, whenever it can be done conveniently. The storekeeper is supplied with specie to the amount of £100, and has instructions to honour such orders. Printed forms for the purpose will be prepared for your use.' The necessary forms were printed in London for issue after Colonel Light's arrival in the new colony. The issues appear to have been limited to sums of 10s. and 2s., the latter being the daily rate of wages of the labourers employed on the survey. The directors of the South Australian Company also provided a paper currency by the issue of orders for 10s., 5s., 2s., and 1s. and 6d. respectively. These notes were all dated from 'Kingscote, Kangaroo Island June 1st 1836,' a date prior to the arrival of the Company's ships at the island, and several months before the site of the new settlement of Kingscote had been determined. Notes to the value of £10, £5, and £1 were also issued by the company. Early in the fifties a number of promissory notes were issued by the South Australian Company and by various merchants. One, issued by Robert Radford, promised to pay the bearer the sum of 2d. in cash.

The outstanding feature of South Australian currency is the coining of what are known as 'Adelaide sovereigns' under an act of the colonial legislature without the permission of the British government. On 9 January 1852 Adelaide merchants petitioned the then governor (Sir Henry Young) to minimize the evils attendant on gold discoveries in neighbouring colonies. Coin was being drained, they said, from South Australia to purchase Victorian gold-dust, which was not a good circulating medium; if the South Australian government could 'receive, assay and coin (i.e. stamp)' the gold, and agree to accept such coins in payment for land-purchases and taxes, the situation could be stabilized. The resulting bullion act (28 January 1852) legalized the assaying and stamping of parcels of gold over 20 oz. in weight, and ordained that banks should exchange their notes for gold bullion at the rate of £3 11s. per standard oz., 22 carats fine. Under this act the government assay office stamped and issued ingots of various weights; the Adelaide banks handled in this shape gold to the value of about 1½ millions sterling. The operation of the 1852

Rubbing from an 'Adelaide Ingot.'

act was limited to 12 months: but an amending act, passed on 23 November, besides authorizing the issue of coins of the value of £5, £2, £1, and 10s., provided for the continuance of the assaying and stamping system so long as not less than 4000 oz. of gold was brought to the office for that purpose each month. Dies were made for coins of the £5 and £1 values, but only about half a dozen £5 pieces were struck, and none put into circulation. Of the £1 pieces nearly 25,000 were struck and circulated: when, however, it was discovered that each contained £1 1s. 10d. worth of gold, they were quickly bought up and the bulk of them exported to England as bullion. On 14 February 1853 the assay office was closed, the amount of gold brought in having fallen below the required limits.

Another novelty in South Australia was a copper coin about the size of a farthing, struck for a man named Tilley Cook in 1855, and inscribed 'Hindmarsh Hotel,' encircling fourpence; and a firm of upholsterers (Congrave) issued little round pieces of leather stamped as pence and halfpence.

Queensland has no separate currency history. In *Western Australia* the earliest currency (1830) took the form of promissory notes issued by the government in payment of work done for it or stores purchased. Such coins as circulated were British; dollars do not seem to have been used. In 1852 it was discovered that a clerk employed to write out the notes had duplicated many of them and forged the official signatures thereto, and the issue had to be called in. A certain Peter Brown appears to have filled the gap with promissory notes of his own, and by 1835 the government departments were accepting private notes in payment of customs duties. In that year, however, the government was itself issuing £1 notes as a temporary expedient, and the commissary reported that on 8 October he had in his chest £148 worth of gold coin, £271 worth of silver coin, and £214 worth of one pound notes. About the subsequent history of Western Australian currency there are no special features; in 1852 British coins were formally made current, in 1856 the Sydney-minted coins, and in 1869 those of the Melbourne mint. In 1894, when it was obvious that Western Australia would be one of the great world-sources of gold, application was made for the establishment of a mint at Perth, and this was opened for business on 20 June 1899.

Tokens.—In the 17th century the lack of small change in England led to the issue of large numbers of 'tokens'—copper coins impressed with the advertisement of the person issuing them, and usually passing current for 1d., ½d., or ¼d. At the end of the 18th century large issues of these tokens were again made, but a large issue of pennies between 1797 and 1805 obviated the necessity for them, and on 27 June 1817 the further issue and circulation in England of tokens was prohibited. The early colonists of New South Wales, as we have seen, used promissory notes of small value to supply the deficiency of copper currency; but the opening up of the Burra Burra copper mines made that metal plentiful enough to allow of the use of tokens in Australia. Annand, Smith & Co., grocers in Melbourne, issued in 1849 1d. tokens struck in Birmingham. The first dated tokens, however, were made in Sydney of Burra Burra copper (or from the funnel of an old steamship) by J. C. Thornthwaite, an engraver who had arrived from England some three years earlier; he had no screw press, and was compelled to cut the coins with a drop-hammer. These tokens were issued by Samuel Peek, a Sydney grocer who owned tea stores and steam coffee mills, and advertised them on the obverse of his token, placing a helmeted figure of Britannia on the

reverse. Thornthwaite also in 1854 struck some silver coins (3d.) to the order of James Campbell of Morpeth; but the first silver token known to Australia is the scarce silver 1s. piece issued by a Tasmanian firm (MacIntosh & Degraves) in 1823—this, however, was not generally circulated, and may have been a memento rather than a coin intended for currency. Between 1852 and 1868 a great number of copper tokens were issued by storekeepers in the various colonies—over 400 varieties altogether. All trades were represented, but a few tokens were issued to commemorate historical events; thus ½d. tokens were issued in Melbourne 'to commemorate the landing of Sir Charles Hotham 22 June 1854,' and a firm of Sydney grocers issued pence and halfpence 'to commemorate the opening of the Sydney Railway 26 September 1865.' By 1863 a demand had arisen for the withdrawal of tokens and the substitution of official coin, and storekeepers in many cases refused to accept tokens. Their prevalence is shown by returns presented to the deputy master of the Sydney mint in 1863, which state that in one case 'out of 68 copper pieces in the till of a shopkeeper, but one was a genuine British coin,' and in another 'but 6 out of 37 were British coins.' The circulation of tokens, however, continued until 1868. On 2 September in that year it was officially announced that old copper coin of the realm would be exchanged for new bronze coin at its full nominal value plus a premium of 2 per cent to cover expenses of collection, packing, and delivery at the mint; that for a period of one month from date copper tokens in circulation would be exchanged at the rate of 240 bronze pence for every 8 lb. of tokens; but that anonymous tokens, those roughly cast and only recently circulated, and evident counterfeits would not be exchanged. These concessions were withdrawn on 22 March 1869. The pieces withdrawn were nominally valued at:—

Old copper coins	£1191	5	2
Old copper tokens	1240	10	4
Total	2431	15	6

The total weight was about 10 tons.

Coinage under the Commonwealth:—The governments of New South Wales and Victoria received permission in 1898 to coin at Sydney and Melbourne silver and bronze for circulation in Australia, but no steps were taken in the matter. Under the federal constitution currency and coinage became federal matters, and in 1909 an act of the Commonwealth parliament provided for Australian coinage as follows:—gold, £5, £2, £1, and 10s.; silver, 2s., 1s., 6d., and 3d.; bronze, 1d. and ½d. Gold was to be legal tender up to any amount, silver up to 40s., and bronze up to 1s. Ultimately the coining was to be done in Australia, but a temporary agreement was made with the London mint, and orders were given for £200,000 worth of silver. The first consignment arrived in Australia early in 1910. Copper coins to the value of £10,000 were also ordered and supplied. Under the federal constitution the issue of paper money is controlled by the Commonwealth, and the parliament in 1910 prohibited the further issue of notes by private banks. Until Commonwealth notes were available, the federal treasurer was empowered to take over the reissue notes of private banks with a Commonwealth surcharge. The new 'Australian' notes, which were first issued in December 1910, were made legal tender throughout the Commonwealth and all Territories under the control of the Commonwealth, and were payable in gold on demand at the Commonwealth treasury in Melbourne. The treasurer was bound by an act of 1911 to hold a gold reserve of not less than one-fourth of the amount of Australian notes issued and not redeemed. Notes were to be of the value of 10s., £1, £5, £10, or any multiple of £10.

As a result of this legislation the private banks' notes, which for many years previously had fluctuated between 3 and 3½ million pounds' worth, were replaced by an issue of Australian notes whose value within two years amounted to 9½ millions; of this amount 5 millions was held by the private banks and 4½ millions was in circulation, while the Commonwealth's gold reserve amounted to nearly 4 millions. The strain of the war greatly altered this position. Towards the end of 1914 it was found impossible to borrow in London for public works within the States, and the federal government agreed to lend five of the State governments (Queensland standing out) £18,000,000; to raise this amount it (among other devices) arranged with the bigger private banks for a loan, not bearing interest, of £10,000,000 in gold, and deposited with them Australian notes for that amount on the understanding that they would not be presented for payment before the end of the war. The gold thus acquired was then used as a reserve to guarantee further issues; gold coin consequently almost ceased to circulate, the note issue was hugely expanded, and at the end of June 1919 55½ millions' worth of notes was either in circulation or in the banks' safes, the gold reserve amounting to 24½ millions. In December 1920 the management of the note issue was transferred to the Commonwealth Note Issue Board (see COMMONWEALTH BANK), and in 1923 there began a new issue of notes with superscriptions corresponding to the change. The note issue remained fairly constant during 1921-3, at a figure slightly in excess of £50,000,000. Notes in circulation on 30 June 1922 amounted to £53,556,698, of which approximately four sevenths were held by the banks and three-sevenths by the public. Against this there was a reserve of gold coin amounting to £23,347,797 10s. (nearly 44 per cent) and, among other assets, investments of the value of £29,658,482.

See Hyman's *Coins, Coinages, and Currency of Australasia* (Sydney, 1893); Chalmers's *History of Currency in the British Colonies* (London, 1893); Atkins's *Coins and Tokens of the Possessions and Colonies of the British Empire* (London, 1889); Gill's *Brief Sketch of the Coinage and Paper Currency of South Australia* (Adelaide, 1912); and Andrews's *Australasian Tokens and Coins* (Sydney, 1921).

Currents, Oceanic. The scientific investigation of the ocean currents whose course lies adjacent to the coasts of Australia has been until lately much neglected. Cook, Vancouver, Flinders, and Bass made some observations on the currents they encountered, as did P. P. King (1820-4), Wickham and Stokes (1837-43), and Denham (1858) while surveying the coast-line; and since 1872 the admiralty has carried out detached coastal surveys, mostly on the northern and north-western coasts. Many isolated observations on the direction and velocity of some of the currents have also been made by chance visitors—the French frigate *La Venus* in 1832, Wilkes in 1840, Sir James Ross in 1841, H.M.S. *Challenger* in 1874, the German survey-ship *Gazelle* in 1875, and the U.S.S. *Tuscarora* in 1874-6.

All these observations, however, were confined to a single season of the year in each case, so that the results obtained must be regarded as applying to that particular time and place only.

It is always dangerous to generalize on insufficient data on any scientific subject, but particularly so as regards ocean currents. There are so many unknown elements in the problem to be solved that its unravelling is only possible through a long series of carefully and accurately conducted measurements. Even the best results obtained by the most competent and highly trained observers can only be regarded as items in a series; and the value of our conclusions must be gauged by the number of items considered, and the care taken to relate them properly to seasons and to certain physical conditions. From the paucity of available observations, therefore, any conclusions concerning Australian ocean currents must be regarded as more or less tentative. This obvious fact has not commended itself to all writers on the subject, and the alleged width, depth, seasonal movements, and ultimate destination of some currents, set out in unequivocal language, though estimated from only one or two observations, have been proved by subsequent measurements to be entirely wrong.

By the general reader, and by the ordinary mariner, an ocean current is taken to mean a movement of surface-water—i.e. of that portion which directly affects the movement of a vessel; but a little consideration will convince us that surface-water (above, say, three fathoms) is the most unstable part of the stream. A solid mass of water hundreds of miles long, scores of miles wide, and hundreds of feet deep, is not turned aside by any temporary disturbance of the atmosphere; yet, if its velocity is sluggish, the movement of its surface-waters may be accelerated or retarded—or even reversed—by long-continued winds from one direction, to be again restored to its normal direction when the wind drops or the direction changes. In this article 'current' means the main body of water, the movements of which are being described; surface, sub-surface and bottom currents are described as such.

Southern Ocean Current.—The southern shores of Australia, for a length of about 2400 miles, are swept by a world-engirdling stream, impelled by the anti-trades or 'roaring forties.' The unobstructed path of these westerly winds completely round the earth, approximately between 40° and 50° S., causes an easterly drift of the surface-water, known as the Southern Ocean current. This creates an indraught of water from the Antarctic, running towards the NE.; and the passage of so vast a quantity of cold water close to our southern shores has a very pronounced effect on the climate of a large portion of the continent. There is also an indraught of warm water from the Indian Ocean—which, having no outlet to the north (as have the Atlantic and Pacific Oceans), must discharge the whole of its warm and comparatively light waters southwards. We are, unfortunately, destitute of information as to the width, depth, velocity, or location of this discharge; but we know of a warm southerly and easterly drift (with seasonal variations) from near Cape Leeuwin at the south-western corner of Australia; and the *Challenger* observations show that a warm current, about 400 miles wide and about 250 fathoms deep, flows in an easterly direction off Cape Northumberland. At Cape Leeuwin it is a surface-current, but at Cape Northumberland is about 150 fathoms down, and has cooled to the extent of about 16° F.

As the great Southern Ocean current of cold water approaches the SW. point of Australia, it meets the warm southerly drift from the Indian Ocean; its waters being heavier, it dips below the warmer stream and flows as a subsurface-current until it meets the shore-line. It bifurcates, probably between 400 and 500 miles SW. of Cape Leeuwin, one part following the western coast of Australia northwards as far as Shark Bay, the other running E. along the southern coast as far as Bass Strait. The branch which flows northward dips under the warm southerly drift from the Indian Ocean, but upwells in the immediate vicinity of the shore-line, forming a cold belt that varies in width according to the strength and duration of the offshore winds. There is not sufficient information to enable us to say how far W. it extends as a subsurface-current.

The southern branch continues as an easterly surface-current across the Bight, with a rate varying from .3 to .4 knot, as far as Spencer Gulf. The warm current from the Indian Ocean, which up to that point appears to be confined to the Bight, dips under and becomes partly merged in the main stream; the combined currents follow the general trend of the shore-line until they strike the Tasmanian plateau. This obstruction blends more thoroughly the warm and cold waters, so that the water in Bass Strait is usually from 2° to 4° F. colder than the water off Cape Northumberland. The Tasmanian plateau also slows down the current-velocity in Bass Strait to such an extent that the tidal currents become the more important; both are, to a large extent, dominated by the wind. The main body of the Southern Ocean current sweeps along the western side of the plateau, turning at the southern coast of Tasmania sharply and with increased velocity to the left, and continues its course NE. and E. round the world.

Eastern Australian Current.—The Eastern Australian current, unlike that of the Southern Ocean, is a stream-current—a branch of the South Pacific Equatorial current, which, after passing S. of the Fiji Islands and New Caledonia, is deflected towards the Australian coast. It first strikes our shore-line near Great Sandy Island, is again deflected (this time to the southward), and flows close alongshore as far S. as Jervis Bay; there the coast-line bends slightly W., but the current continues its direct course until it impinges upon the eastward-flowing Southern Ocean current in about 43° S. It is here split into three portions. The first is bent round and flows E. as a warm surface-current; the second is also carried E., but mixes with the colder current and helps to account for the rise of temperature—from 41° to 50° F., according to the season—which is observed between 50° and 40° S.; the third—the water that has already become cooler and therefore heavier—sinks below the cold surface-water, takes a south-easterly course, and flows as a comparatively warm under-current into the Antarctic Ocean. This warm water, in conjunction with that of the Brazilian current in the South Atlantic, and the Agulhas or Cape current of the Indian Ocean, undermines the enormous ice-masses that form the 'ice barrier,' and detaches from them numerous floating icebergs, which strew the face of the Southern Ocean even in 50° and 40° S. These ice-masses, melting, produce water which, being of less specific gravity than the salt water of the sur-

rounding sea, at first floats upon it; eventually, however, the two layers blend (combining the density of the salt with the temperature of the fresh water), and sink, becoming the source of the masses of cold water which, to a depth of several thousand fathoms, fill up the basins of the Atlantic, Pacific and Indian Oceans.

The eastward surface-current, meanwhile, continues its journey till it strikes the western coast of New Zealand, where it is again deflected N. along that coast as far north as Cape Maria Van Diemen; there it turns W. and is lost in the waters of the Tasman Sea.

Between Great Sandy Cape and Jervis Bay the Eastern Australian current (for which the name 'Tasman current' has been proposed) has at 34° S. a width of 350-400 miles and a depth of about 100 fathoms. Its velocity on the New South Wales coast, at all times and seasons, is about 1½ knots at the littoral, and about 2 knots in the offing. Between Jervis Bay and Bass Strait the direction and velocity of this current is variable, as it is very sensitive to interference from a northerly extension of that part of the Southern Ocean current which flows E. through Bass Strait. The area between the shore and the western edge of the Tasman current is occupied by branches of the warm and the cold currents alternately, according as the wind blows from the south-western or from the south-eastern quadrant. On the west coast of New Zealand the temperature of the stream is from 8° to 10° F. warmer than on the east coast, but the information available is not sufficient to enable us to state its dimensions.

The western equatorial drift in the eastern South Pacific, caused by the SE. trades, will be found to extend to about 20° or 22° S. As already said, a portion of its waters is deflected towards the Australian coast at about New Caledonia; the rest flows NW. towards Cape York, and so through the Arafura Sea. Within the triangle formed by New Caledonia, Cape York, and the Chesterfield reefs, the currents are uncertain both as regards direction and velocity, being influenced largely by the prevailing winds—and, when close to the shoreline, by very complicated tidal currents, which are partly produced by local conditions among the numerous islands.

Arafura Sea Currents.—In the Arafura Sea the current generally sets with the wind, its course in the SE. monsoon season (from the beginning of April to the beginning of October) being W. The velocity depends much upon the force of the wind, but seldom exceeds 1 or 1½ knot. Along the northern side of the Sirmatti Islands—between Timor and the Tenimber group —the current sets E. (to windward) during the SE. monsoon season. During the NW. monsoon the currents in general set E.

On the NW. and W. coasts of Australia the current, though generally setting with the wind, is sometimes uncertain both in velocity and direction, being complicated with strong tidal currents which prevail in those parts. The range of the tides between Van Diemen Gulf (in 132° E.) and Dampier Archipelago (in 116° 30′ E.) is abnormally great, ranging from 19 to 38 feet at springs; the average of 22 stations is 26 feet. The greatest rise and fall on this coast—38 feet—occurs in Hanover Bay (in 124° 45′ E.) but at neaps the range is reported to be at times only two feet. Such large masses of water, entering and leaving the gulfs and bays, necessarily cause serious indraughts and extensive outdraughts, and these, being further complicated by great diurnal inequality, are a menace to safe navigation.

To the W. and S. of Dampier Archipelago the range of the tides lessens, being about six feet at North-west Cape and dwindling to about two feet at Fremantle. On this part of the coast the currents, as already said, are sluggish and uncertain. The warm drift from the Indian Ocean and the relatively cold current from the Southern Ocean encroach upon each other alternately, with the result that the offshore and onshore winds often dominate the set. The prevailing winds have a tendency to blow from the western quadrants, thus setting a vessel towards the land when in the vicinity of the coast.

G.H.H.

Cuttle-fish. See MOLLUSCA.

Cyanostegia, a genus of the family Verbenaceae, consisting of shrubs, mostly endemic in Western Australia. The flowers are blue; calyx broadly bell-shaped; leaves opposite. The frilled papery calyx, with a sinuate toothed margin, enlarges as the corolla withers, and retains its form and colour, simulating the 'everlastings.' The leaves are often covered with a glutinous exudation.

Cycadaceae, a family of palm-like plants extending over tropical America, subtropical and southern Africa, and tropical Asia. Three genera are indigenous to Australia. The flowers are unisexual, on different plants, without calyx or corolla; the males consist of scales bearing anthers, the females of cones (also represented by scales) on which the naked ovules are seated. The endemic genus *Macrozamia* has 16 species. The kernels of the nut-like fruits of various species, after being pounded, macerated and baked, form an important article of aboriginal food. They contain a large quantity of starch, which is easily obtained by washing the crushed kernels; if eaten without preparation (i.e. washing or cooking) they are very poisonous. Officers of the Flinders expedition suffered severely from eating the raw nuts of *Macrozamia Fraseri*—'a fruit not much unlike green walnuts in external appearance'—at Lucky Bay near Esperance in the Bight; and those of *Cycas media* not only gave Cook's midshipmen 'a hearty fit of vomiting,' but killed several of his pigs. A fair quantity of good arrowroot is obtained from them, and experiments have also been made for the production of a commercial starch and alcohol. A gum analogous to tragacanth is obtained from several species. *M. Hopei,* of northern Queensland, is the largest member of the genus. It is said to attain a height of 60 feet. *M. Fraseri* is peculiar to Western Australia. See BURRAWANG.

Cynometra, a widespread tropical genus of the family Leguminosae, consisting of trees or shrubs. The flowers are small, usually reddish in lateral clusters; leaves with one or two pairs of leaflets; pod semi-orbicular, fleshy and swollen. The wood of *C. ramiflora* yields a purple dye. In India the seeds are used medicinally in skin diseases, and the hard, coarse-grained wood is used for houses and native carts.

D

Dabchick, Little Grebe, or Black-throated Grebe (*Podiceps gularis*). See Grebes.

Daglish, Henry (1866-1920), born at Ballarat on 18 November 1866 and educated at Geelong, was in 1882 apprenticed to an engineering firm at Geelong, but in 1883 abandoned the trade for the Victorian public service. In 1895 he resigned, made an unsuccessful attempt to enter Victorian politics, and at the end of 1896 moved to Western Australia, joining the public service of that colony in January 1897. He resigned in 1901, and was elected from Subiaco to the State legislative assembly as a Labour member; in 1904-5 he was premier, heading Western Australia's first Labour ministry. He left the party, however, in 1905; in 1907-10 he was chairman of committees, and in 1910-11 minister for works in the first Wilson ministry. In 1912 he was appointed employers' representative in the arbitration court, and in 1914 was defeated at Subiaco and retired from politics. He died at Perth on 16 August 1920.

Dairying. The dairying industry in Australia was necessarily limited by the small local demand until improvement in the processes of refrigeration, towards the end of last century, made it possible for the farmers to develop an overseas trade. The Australian climate offered certain competitive advantages—e.g. except in a few localities stock can thrive in the open throughout the year, though practical experience has demonstrated the value of rugging the herd during the colder months and of providing tree-shelters—but the industry was handicapped by the poor breed of cattle, the intermittent droughts which led to irregular feeding, and the farmers' general ignorance of scientific methods. Since the eighties, therefore, efforts have been made by farmers, with the active co-operation of the State governments, to overcome these disadvantages. Stud cattle with good dairying qualities have been imported both by governments for State agricultural farms and by private individuals, and experiments in breeding have been made with the object of securing dairy stock suited to the Australian environment. As a result the average yield of milk has considerably increased, though it is still comparatively small, the 343 gallons per cow obtained in 1921 constituting a record for the Commonwealth. Special attention is paid to butter-producing qualities rather than to quantity, as it is the overseas butter-market that farmers hope especially to develop. Pasturage has also been improved by the eradication of herbage of little or no use and the planting of suitable grasses, though many indigenous varieties are excellent for stock and possess both milk-producing and fattening properties. To secure a regular food-supply more attention is being paid to the preparation of ensilage, as is necessary in a country subject to periods of drought. By a system of mixed farming it has been found possible to extend the industry to non-coastal and thinly-grassed districts, sufficient fodder being grown to carry the cattle through the winter months. The State agricultural departments send experts round the country to give practical demonstrations in approved methods of production; model dairies are also fitted up on most of the experimental farms; and advice is given through agricultural gazettes and special bulletins. Since the eighties there has also been a rapid improvement in the processes of manufacturing dairy products suitable for export, and butter, cheese, and preserved-milk factories have been established, usually on co-operative lines. As a rule the cream for butter factories is separated at the dairies, modern machines being used by most farmers. Generally speaking, the interests of consumers in the cleanliness and purity of dairy products have been safeguarded by the State and Commonwealth governments. It is not lawful to sell or offer for sale milk which is not fresh and wholesome or which has been adulterated in any way. Regulations provide for the supervision, by specially appointed inspectors, of dairy farms and herds, dairies and factories, all of which must maintain a prescribed standard. Dairymen, milk vendors, and factory proprietors are required under penalty to be registered. Every dairyman or milk vendor is required to report immediately when any person engaged at (or residing on) his premises has contracted any one of certain infectious diseases, in order that they may be effectively isolated. Any animal contracting a notifiable disease must be at once isolated, and the fact reported. The sale of milk from an infected cow is prohibited, and the inspector may order the animal to be destroyed. The foreign consumer is protected by Commonwealth regulations issued under the commerce act of 1905. All dairy products intended for export must be sent for inspection to appointed places, and an exact trade description must be permanently affixed thereto. The export of unsound, inferior, or abnormal dairy products is prohibited, unless the trade description applied to the goods includes the words 'below standard.'

As a result of this care and supervision the dairy industry in Australia has steadily developed since the eighties—except during the drought of 1914-16, when the herds were severely depleted. Most of the observations and conclusions embodied in the report of the Scottish agricultural commission (published in Edinburgh in 1911 under the title *Australia: its Land, Conditions and Prospects*) hold good for the present time, and constitute an excellent study of dairying conditions in the Commonwealth. But legislation passed by the Commonwealth parliament in 1924 creates new supervising authorities which are intended to standardize production in all the States. On these 'advisory boards' every section of the industry is represented as well as

the Commonwealth and State governments. The sphere of activity of each section is defined, and provision has been made for the adoption of a national brand, so that Australian dairy products may be recognized as such and accepted as of a given quality in the world's markets.

Historical Sketch.—Through the scarcity of cattle the first settlers were largely dependent on goats for their supply of milk. The government policy of maintaining a state herd and exchanging breeding cattle for the produce of the land was distinctly beneficial. About 1820 (according to Dr. Lang) cheese-making was introduced by George Rankin of Kelloshiel near Bathurst, and by 1836 large quantities of butter and cheese were being manufactured, and formed a considerable article of export, chiefly to Tasmania. The Hunter River soon gained distinction for its rich pastures. In 1826 the president of the local agricultural society referred to the need for exporting surplus dairy produce; nevertheless large quantities of butter were still imported from the Cape and Ireland in hermetically sealed vessels.

New South Wales.—For many years the Illawarra district was recognized as the most important dairying district of Australia; it was, indeed, so admirably adapted for dairying that the industry by degrees extended farther south to Ulladulla, Moruya, and Bega. Alexander Berry (q.v.) of Shoalhaven formed a good dairy herd, and in 1849 exported considerable quantities of butter to California. A fine race of dairy cattle, known as the Illawarra shorthorn, was evolved, probably from selective crossings of the Ayrshire with the milking shorthorn. During the fifties butter was sometimes sold wholesale at 2s. 6d. to 3s. per lb.; but the supply during the summer months exceeded the local demand, and prices would recede to perhaps 6d. per lb. The surplus was then exported to other colonies (chiefly Victoria); in 1853 79,990 lb., valued at £6636, was so disposed of. 'The progress of dairying from 1852 to 1883' says J. P. Dowling, 'was made under the old system, advances being made at Bodalla (south of Moruya) by the late Thomas Mort, and by Messrs. Fox, Tooth and Wren and other energetic settlers at Bega. In these districts were established factories furnished with all the best American cheese-making appliances, and the South Coast soon obtained a great and lasting reputation for cheese and bacon.' The introduction of cream separators at Mittagong by the Fresh Food and Ice Company in 1881, and of the co-operative factory system at Kiama in 1884, marked an epoch in the industry. Co-operation and herd-testing had been advocated for years by D. L. Dymock of Kiama, who instituted the *Herd-book.* He travelled widely, examining European and American systems of dairying, and brought to Australia the first Laval cream separator. The co-operative factory system gradually gained ground; in 1888 eight factories were at work, costing from £1500 to £2000 apiece and each taking milk from about 50 dairymen.

Hand-made butter, exported at this time in small quantities to London in the cool chambers of the Orient Company's steamers, realized 10½d. per lb., factory-made butter sent about the same time realizing 1s. This experiment led to a remarkable development of the industry. Butter was also exported to Queensland, Western Australia, Batavia, Calcutta, Bombay, Singapore, and Hong Kong. In 1891 the quantity of butter made under the old system was 10,484,474 lb., and of that made in butter factories only 8,049,656 lb.; but in 1900 the old system produced 4,216,134 lb. only, and the factories 18,817,747 lb. In 1891 there were 124 butter factories, to which milk was delivered, there being then no local separating creameries and no home separators; in 1900 there were 168 butter factories and 387 creameries.

Soon after 1888 there was a remarkable development of dairying in the subtropical Richmond River district. This district had been occupied chiefly by growers of sugar-cane, but a great fall in the price of sugar ruined many residents, and the government, when appealed to, suggested dairying as an alternative. The advice was acted upon; much of the country was cleared; dairy cattle were obtained, for the most part from the south coast districts, new settlers arrived, co-operative butter factories and creameries were established, and in a few years the largest butter factory in the world was in full swing at Byron Bay. A great deal of the region was covered with dense vegetation, but devoid of natural grasses. By 1913 there were 251,198 dairy cows in the north coast district, producing 107,462,642 gallons of milk, from which 43,650,510 lb. of butter and 401,677 lb. of cheese were made; 871,191 acres were under artificial grasses.

The introduction of small hand or power separators on farms proved extremely convenient for the farmers, who were saved the trouble and expense of conveying milk to the creameries or factories, and carting back to the farm skim milk for the pigs. Unfortunately, separation on the farms frequently resulted in the production of inferior butter; the cream, delivered at the factory only twice or thrice a week, was liable to become tainted, and one tainted can would affect a whole churning, for all creams were mixed together. To obviate this, the State's agricultural department urged legislation to compel the grading of cream at butter factories, and in 1915 the dairy industry act became law. Since that time a great improvement has taken place in the quality of cream delivered at butter factories, and a still greater improvement in the quality of butter placed before the public.

In 1902 steps were taken to provide instruction in dairy methods; a travelling dairy was equipped and sent about the country, and a well-equipped dairy provided instruction for students at the Hawkesbury Agricultural College, while similar instruction was given at the Wagga, Bathurst, Richmond River, Grafton, and other experimental farms. A stud farm was provided at Berry in the Illawarra district for dairy cattle of the best breeds obtainable in England, and an expert in cheese-making travelled through the dairying districts, giving instruction in the manufacture of high-class cheese. In New South Wales the industry is regulated mainly by the dairies' supervision act of 1901. Dairymen, milk vendors, and the proprietors of creameries and dairy factories must be registered. Inspections are made by 14 district inspectors under a chief dairy inspector. In 1922 fines to the amount of £2000 were imposed for adulteration of milk, lack of cleanliness, and similar offences. The figures for the period 1919-23 give an annual average as follows:—dairy cows, 766,802: milk, 241,458,721 gallons: butter, 80,436,192 lb.: cheese, 6,433,909 lb.: and condensed or concentrated milk, 9,578,227 lb.

Victoria.—In this colony also the industry received a new impetus towards the end of last century when improvement in the processes of

refrigeration made it possible to bid for a world-market. A royal commission on vegetable products in 1888 pointed out that Victorian farmers were, on the whole, slower than those of the Illawarra to adopt the new system of factory production with modern machinery, and recommended direct encouragement of the industry by bonuses for butter and cheese manufacture, and by establishing model dairies for instruction. Both recommendations were adopted; throughout the colony co-operative butter factories were established, and by 1892-3 the production of butter for export—which in 1889-90 only amounted to 828,882 lb.—had increased to 8,099,258 lb. The cheese industry was also developed, especially in the western district, and to a less extent in Gippsland; to encourage this branch of production the government obtained the services of an expert acquainted with Canadian methods. In 1890 a factory was established at Bacchus Marsh for the manufacture of preserved and concentrated milk on a commercial scale. By the end of the century the earlier shorthorn and Hereford cattle were gradually being replaced or crossed with Ayrshires, Jerseys, and other good dairy breeds; at the same time the process of cutting up large estates for dairying purposes was accelerated. The industry suffered severely during the drought of 1915-6, but development has been fairly continuous since that time. Acts which provide for the registration, inspection, and supervision of dairies, dairy farms, dairy produce, milk stores, milk vessels, dairy cattle, and grazing grounds are administered by the department of agriculture, though local authorities have the option of carrying out this duty within the limits of their jurisdiction; the department of health is also empowered to test foods, including dairy products, and to prosecute in cases of adulteration, etc. Under an act of 1922 the council of any metropolitan municipality (or a group of councils acting together) may establish depots at which milk may be bought, treated, and sold. In an area in which there is a municipal depot no milk may be sold unless it has been treated in a depot, or by approved methods in a factory. Provision is also made for the establishment of a laboratory of research in matters relating to milk. The figures for the period 1919-23 give an annual average as follows:—dairy cows, 689,507: milk, 223,977,333 gallons: butter, 73,123,728 lb.: cheese, 2,700,616 lb.: and condensed or concentrated milk, 43,382,932 lb.

Queensland.—In 1888, when the success of dairying in the southern colonies was assured, the government of Queensland obtained the services of a dairy expert, a well-equipped travelling dairy was procured, and instruction was given to farmers who desired to embark on the industry. At the time there were no more than half a dozen cream separators in the colony; of factories there were none worthy of the name, and it is doubtful whether a complete and properly equipped cheese-plant could have been found. From these small preliminary efforts an important industry was built up, and by 1895 the importation of butter and cheese had practically ceased. In 1888 the total amount of butter produced in the colony was 1½ million lb., and of cheese practically nothing; by 1894 the output of butter had trebled, and of cheese 1,536,997 lb. were made. The chief producing districts were Warwick, Brisbane, and Toowoomba. In 1895 was made the first experiment in exporting cool storage butter from Queensland, 7½ tons being shipped to London; by way of further encouragement to the dairy industry, a tax was levied upon owners of dairy cattle, and the proceeds were used for aiding the erection of butter and cheese factories, or for a bonus on these articles. In 1896-7 some 63 tons of butter were exported; the official report on that season's dairying states that the value of co-operation was becoming better understood, and it seemed likely that proprietary factories would sooner or later give place to co-operative factories. Next season the dairy expert reported that ordinary dairy cattle had increased in price at least 70 per cent during the year, and land that a few years before was practically unutilized, because unfit for agriculture, was carrying dairy herds. Steps had been taken to improve the herds, but the supply of well-bred cattle was still inadequate. In 1900 there were at work 53 butter and cheese factories and 146 creameries employing 595 persons. The output that year was 5875 tons of butter and 886 tons of cheese, valued altogether at £656,177; 620 tons of butter were exported. At that time dairy produce for England had to be shipped in intercolonial steamers to Sydney, and transferred there to oversea vessels.

The dairy produce act of 1905 revolutionized the industry. It provided not only for the inspection of dairies, dairy farms, and factories, but also for the appointment of grading inspectors to classify butter intended for export. In 1908 an amending act insisted that cream should be graded for manufacture into different qualities of butter, and no person was allowed to grade cream until he had obtained a certificate of proficiency. A year or two earlier the necessity for transhipping Queensland butter at Sydney had been avoided by inducing certain mail-steamers to call at Brisbane, the Queensland government paying a subsidy of £26,000 a year. The dairy produce act of 1920, which applies to the whole of the Queensland coast from Rockhampton southward, as well as to the Darling Downs and the districts of Maranoa, Mackay, and Cairns, is administered by the department of agriculture; under it in certain proclaimed areas the sale of milk is confined to persons licensed under an act of 1917, and is supervised by inspectors of the department of health.

A good deal of dairying is done on the share system (see AGRICULTURE). Owners of large estates and agricultural holdings cut them up into a number of small dairy farms run by experienced dairymen; the owners provide all necessary appointments (buildings, dairies, stock, implements, etc.), and profits are shared equally. This system prevails in the coastal area south of Brisbane. At Toogoolawah in the Brisbane valley a condensed-milk company has six model farms, comprising 4000 acres, 1200 acres of which are under cultivation for maize, lucerne, millet, and other grains. The figures for the period 1919-22 give an annual average as follows:—dairy cows, 484,918: milk, 115,407,061 gallons: butter, 45,418,420 lb.: cheese, 11,392,356 lb.: and condensed and concentrated milk, 11,825,766 lb.

Tasmania.—About 1858, according to M. H. Hull, butter and cheese were exported from this colony to the value of £16,000 per annum, the price of the butter being 2s. a pound. Ayrshire, Hereford, and Devon cows, bred with care, were used for dairy purposes. 'These animals,' said Hull, 'are taking the place of the cross between the bison and Brahmin cows which we used to have, and which had to be knocked down with a long pole and roped head and feet before they could be milked. It was at one time no unusual

thing for the milkman, after a turn of seven miles in the bush, to be tossed in the air by one cow and his shins kicked by another before he could succeed in inducing her to part with the usual pint of milk for the family's breakfast.' But the progress of dairying in the island—so eminently fitted for it by nature—has been inexplicably slow. As late as 1903 there were only 15 Tasmanian butter factories, producing less than a million lb. of butter, and the output of cheese was little more than half a million lb. The figures for the period 1919-22 give an annual average as follows:—dairy cows, 66,585: milk, 19,375,690 gallons: butter, 4,823,019 lb.: and cheese, 902,882 lb. The industry is supervised by local authorities, usually under by-laws drawn up by the department of public health; the same authorities are empowered to take samples of milk as a guard against adulteration.

South Australia.—Improved methods of dairying in this colony date from about 1885, when the colonial government began to assist the farmers by (*a*) supplying instruction in dairying methods and (*b*) facilitating the export of dairy produce. In 1890 the colony exported to England 10,850 lb. of butter, and in 1891 doubled the amount. By 1893-4 the production of butter was almost six million lb. and of cheese almost one million: three years later the approximate amounts were 9 million and 1¾ million; the peak was reached in 1910, when 10¾ million lb. of butter were produced—a figure not reached again until 1920. The industry is controlled throughout the State by the foods and drugs act of 1908, which is administered in the Adelaide area by the metropolitan county board and in the country by the board of health. The figures for the period 1919-23 give an annual average as follows:—dairy cows, 122,755: milk, 37,252,095 gallons: butter, 12,729,961 lb.: and cheese, 2,749,711 lb.

Western Australia.—An official report of 1891 recommended dairying as an industry that could be followed with advantage in the coastal area of Western Australia from the Moore River southwards as far as Cape Leeuwin and inland to the dividing range. But as late as 1911 the industry remained practically undeveloped, though during 1910 butter to the value of £342,771, preserved milk worth £78,492, and cheese worth £36,805 had to be imported. In June 1912 the chief inspector of stock reported that dairy cattle in the State had diminished by about 3000 head in one year. To encourage settlers to take an interest in dairying, the government then established a state farm at Brunswick, where pure Ayrshires are kept and bred. But the increase was small until 1916, when the dairy cows numbered 33,788, and a more rapid development followed. The public health authorities regulate the dairying industry in Western Australia, the premises of dairymen and milk vendors being registered and supervised by health inspectors; officers of the department of agriculture examine dairy herds at regular intervals, and apply the tuberculin test where disease is suspected. The figures for the period 1919-22 give an annual average as follows:—dairy cows, 50,732: milk, 10,775,631 gallons: butter, 2,404,318 lb. The production of cheese is insignificant.

Between 1912 and 1915 the number of dairy cattle decreased greatly; in 1915 it was only 1,684,393, with a milk production of less than 435 million gallons, and the 1912 standard was not regained until 1920. Apart from the increase in the production of condensed milk, due to the establishment in Australia of branches of several important European firms, the most noticeable feature of Australian dairying in recent years is the great increase in the average yield per cow. Before 1916 this was considerably under 300 gallons per annum; but more systematic breeding and herd-culling and the adoption of milk-testing systems in the more advanced States had by 1921 brought the average above 300 gallons in all States except Western Australia. For that year the average yield over the whole Commonwealth was 343 gallons, and in New South Wales and Victoria 363 and 366 gallons respectively. The world's record for milk-production—891b. per day for a year—is held by 'Melba XV,' a pure-bred shorthorn from Gundagai in New South Wales which from 14 June 1923 to 13 June 1924 produced 32,522½ lb. of milk, yielding 1614 lb. of butter-fat: her average test was 5 per cent.

For the Commonwealth as a whole the following statistics are interesting:

	1910	1920	1922
Dairy Cows	2,064,599	2,055,638	2,419,809
Milk (gallons)	572,998,277	623,285,221	685,309,582
Butter (lb.)	193,425,606	208,081,864	234,995,009
Cheese (lb.)	16,537,011	24,160,524	23,710,559
Concentrated and condensed milk (lb.)	12,491,261	70,944,482	51,460,739

W.S.C.

Daley, Victor James William Patrick (1858-1905), born at Navan in Ireland on 5 September 1858, lost his father in infancy, lived with his grandparents in county Armagh while a child, and when his mother married again was sent to school at Devonport in England. In 1874 he entered the employ of the Great Western Railway, but tired of it after three years and migrated to Australia, reaching Sydney early in 1878 and eventually finding work in Adelaide. Thence he drifted to Melbourne, became a free-lance journalist, and in 1881 returned to Sydney via Queanbeyan (where he had hoped to go gold-digging) and contributed to *Sydney Punch* and the then newly started *Bulletin.* In 1885 he went back to Melbourne, and for the next 13 years earned a precarious living by journalistic work, largely poetical; in 1898 a volume of verse by him, *At Dawn and Dusk,* was published in Sydney, and the New South Wales government was induced to give him a departmental clerkship; but he could not endure the routine, and disappeared from the office to resume his free-lancing. In 1902 his health failed, and friends arranged for him a voyage to the South Seas in 1903; in 1905 it was discovered that he suffered from tuberculosis, and on 29 December of that year he died at Waitara near Sydney. A second volume, *Wine and Roses,* was published posthumously in 1911.

Daley's work was unique in the Australian poetry of his time. The bush had little charm for him, except as a sunny and temporary refuge when city life grew too strenuous; and three-quarters of his verse might, as far as internal evidence goes, have been written anywhere in the world—except for the perpetual glow of sunlight through it. That, and the inspiration to seek romance in the present which vivifies his first book, were Australia's gifts to him; in the posthumous volume it has disappeared, to be replaced by a glamour of past romance that is purely Irish. Regarded simply as poetry, his work at its best is probably the best done in Australia.

Dalley, WILLIAM BEDE (1831-1888), born in Sydney in 1831 and educated at the Sydney College and at St. Mary's school—where he came under the influence of Dr. Polding—was trained for the law and called to the New South Wales bar in 1856 (Q.C., 1877). At the end of 1856 he entered politics, succeeding Henry Parkes as member for the city of Sydney in the first parliament under responsible government. In the second parliament (1858-9) he represented the Cumberland boroughs, and in the third Windsor, but resigned his seat on 25 February 1860. For three months (November 1858 to February 1859) he was solicitor-general in the second Cowper ministry. His eloquence marked him out as a valuable asset to his party, and he was one of the 21 new members whom John Robertson appointed to the legislative council in May 1861; but almost immediately Robertson offered him the post of commissioner of emigration, with Parkes as his fellow-commissioner. They reached England on 4 August, and at once began their work of stimulating voluntary migration, Dalley taking the home counties and Ireland as his sphere while Parkes toured Scotland and the west and north of England. In June 1862 Dalley resigned his post and returned to Sydney, but did not again take up politics seriously for many years, though he represented Carcoar from October 1862 to November 1864, and was a member of the legislative council from May 1870 to September 1873. In 1875 Robertson, then in the middle of his long struggle with Parkes, put Dalley back in the council and made him attorney-general in his third and fourth ministries (February 1875 to March 1877, August to December 1877); but for the next five years he again abandoned politics—resigning from the council in 1880—and it was only the coalition under Alexander Stuart, which ended the long rule of the Parkes-Robertson coalition, that persuaded him to reappear in the council and become Stuart's attorney-general on 5 January 1883. This time, however, his term of office was memorable. In October 1884 Stuart fell ill, and Dalley became acting premier. Early in 1885 the peril of Gordon at Khartoum was engaging the attention of the whole Empire. The news of Gordon's death—with its probable consequence, a Mahdist invasion of Egypt—stirred Australia profoundly; and Dalley, urged by a friend (Sir Edward Strickland) but with the zeal of an originator, offered Britain a contingent of infantry and artillery for service in the Sudan, and with all his eloquence roused New South Wales to raise and equip the necessary troops. The story of this 'Sudan contingent' is told elsewhere under that heading. The offer excited much enthusiasm in England (where it had been widely supposed that the Australian colonies were indifferent to Imperial affairs and almost ripe for secession), and Dalley gained renown as the first practical exponent of colonial loyalty; he was offered a knighthood, and could have had the chief-justiceship when Sir James Martin died in 1886, but refused both honours, and only under pressure consented in 1887 to be made a member of the privy council—the first Australian to receive that distinction. He died at Sydney on 28 October 1888.

Apart from the Sudan expedition, Dalley left no permanent mark on his times. He was, however, a great influence among his private friends (most of whom were publicists) for culture and tolerance and the adoption of world-standards rather than parochial. His eloquence as an orator was almost equalled by his facility as a writer; but neither faculty was put to its full use, and his fame will rest mainly on the one gesture by which he convinced not only Britain, but Australia, that the colonies too were British at heart.

Dalrymple, ALEXANDER (1737-1808), born near Edinburgh on 24 July 1737 and made a writer in the East India Company's service at the age of 15, took up his duties at Madras in May 1753 and a year or two later, having been noticed and favoured by Governor Pigot and Robert Orme the historian, was promoted to be deputy-secretary to the council. Developing ambitious plans for the extension of the Company's trade, he was allowed in 1759-62 to cruise in the Malay Archipelago, seeking new ports and privileges; he was thus present at the taking of Manila by an English fleet in October 1762, and discovered in the archives of that city a copy of the report made by Luis Vaez de Torres (see AUSTRALIA, DISCOVERY OF), on his voyage from the New Hebrides. Dalrymple at once saw that Torres had actually passed between New Guinea and New Holland through a strait which was marked in all recent maps as dry land; he therefore named the strait after its (unconscious) discoverer. Returning to England in 1765, he two years later published an *Account of Discoveries in the South Pacific Ocean before 1764*, which established his reputation as a geographer and induced ministers to nominate him as commander of the South Seas expedition of 1768; by demanding, however, that he should receive a commission as captain in the navy, which the admiralty flatly refused to give him, he lost the appointment—which was then given to James Cook. Hurt at the loss, and jealous of his supplanter, Dalrymple afterwards tried to belittle Cook's achievements by suggesting (without the slightest justification) that he had merely followed existing charts and had made no new discoveries. In 1775 he returned to Madras as a member of council, but after two years' service was recalled undeservedly, and in 1779 was made hydrographer to the East India Company. When in 1795 the admiralty created a hydrographic department, Dalrymple was made head of it; while well-informed, zealous and an excellent organizer, he was also indiscreetly arrogant, and in May 1808 was dismissed. This, the second great disappointment of his life, broke his heart, and he died on 19 June following. Besides the book already mentioned he published several books and pamphlets, the most important of which is his *Historical Collection of South Sea Voyages* (2 vols., 1770-1). Port Dalrymple at the mouth of the Tamar River in Tasmania was named after him by Governor Hunter in 1798.

Daly, SIR DOMINICK (1798-1868), born at Ardfry in county Galway, Ireland, on 11 August 1798 and educated at Oscott College near Birmingham, entered the colonial office; in 1822 he was made private secretary to Sir Francis Burton, lieutenant-governor of Quebec, and in 1825 assistant-secretary to the Quebec government. He served in Quebec until 1848, then returned to England, and in 1851 was made lieutenant-governor of Tobago and in 1854 of Prince Edward Island. In 1859 he resigned this post and went on leave, but in October 1861 was gazetted governor of South Australia. This appointment was made for special reasons. On the previous governor, Sir R. MacDonnell, had fallen the task of introducing responsible govern-

ment, and he had in the process involved himself in numerous disputes with his ministers and the legislature; his successor, therefore, must be both tactful and experienced in colonial government, and Daly—who had served in a subordinate position through the troubled times of Lord Durham's rule in Canada, and had been both an elected representative and a minister there under responsible government—seemed exactly suited for the position. He fulfilled expectations. Although during his term he was confronted with several awkward crises (notably the recalcitrance of Judge Boothby (q.v.), and the troubles incidental to the settling of the Northern Territory), he remained calm and impartial, loyal to his ministries—and there were ten of them in six years—but exercising a moderating and wise influence over all. Towards the end of his term his health failed, and he died in Adelaide on 19 February 1868. (Kt. Bach., 1856.)

Dampier, ALFRED (1847-1908), born in London on 28 February 1847 and educated at the Charterhouse, made his first appearance as an actor at Stratford-on-Avon, and subsequently travelled the English provinces. In 1872 he was engaged by H. R. Harwood to play in Melbourne, where he first appeared as Mephistopheles in his own version of *Faust*. For three years he played leading Shakespearian parts in Melbourne, and then returned to England via Sydney, Adelaide, New Zealand, and the United States. After a season at the Surrey Theatre he revisited Australia, leased a theatre in Melbourne, and produced in it (and in many other Australian and New Zealand towns) a series of Australian plays of which the most noteworthy was founded on Rolf Boldrewood's *Robbery Under Arms* (written in conjunction with Garnet Walch, q.v.). Two of his daughters, Lily and Rose Dampier, shared in his successes and were regarded as competent actresses. He did not confine himself to melodrama, but persistently interpolated Shakespearian revivals, and for many years was the only manager (except George Rignold) who kept the Australian public familiar with Shakespeare's plays. He died at Sydney on 23 May 1908.

Dampier, WILLIAM (1652-1715), born in 1652 at East Coker in Somerset, was intended by his parents for trade; but his father died in 1662 and his mother in 1668, and his guardian willingly let him follow his own inclinations. He was therefore 'removed from the Latin school to learn writing and arithmetic,' and within a year had shipped aboard a Weymouth merchantman for voyages to France and Newfoundland. Next he joined an East Indiaman for a voyage to Java, and early in 1673 shipped as able seaman in H.M.S. *Royal Prince* under Sir Edward Spragge, the most daring captain of the naval war with the Dutch. Invalided in August, and finding Spragge dead and the war over when he recovered, he accepted at the beginning of 1674 a post as sub-manager of a plantation in Jamaica; tiring of this after six months—for he was incurably a rover by disposition—he joined a Jamaica coast trading vessel, and in August 1675 sailed for Campeachy Bay in Yucatan and entered the logwood industry. The Bay was in Spanish territory and the trade forbidden, so that there was no long step from logwood-cutting to buccaneering, and Dampier was soon a buccaneer—but incidentally and as a means to extending his travels, not deliberately or for gain. He visited England in 1678-9, and on his return intended to take up logwood-cutting again, but was diverted to share in a trading expedition to the Mosquito Coast, and suddenly found himself in the thick of a buccaneer raid. From 1680 to 1682 he was a member of a daring gang which raided Portobello on the coast of Colombia, crossed the isthmus to Panama, failed in an attack on that town, seized a ship and coasted South America as far as the island of Juan Fernandez, and after attempting Arica and Coquimbo was forced to re-cross the isthmus by Indian paths under conditions of extreme danger. In 1682-3 Dampier spent an unhappy but comparatively restful 13 months in Virginia; then, impatient for more adventure, he joined another privateer (the *Revenge*, John Cook, master) bound for the west coast of South America via Cape Horn. On the way they captured a Danish vessel and used her to replace the *Revenge*, naming her *The Batchelor's Delight*, and in September 1684 they were joined by a certain Captain Swan in the *Cygnet*. Again the coast towns were raided and Spanish vessels captured as far north as Costa Rica; but no good leader showed himself, the buccaneers grew desperate with many failures, and in August 1685 Dampier joined Swan, who was eager to try new hunting grounds in the western Pacific. On 31 March 1686 the *Cygnet* left the Mexican coast to make for Guam in the Ladrones, reached the island with a half-starved crew, and on 21 June anchored off Mindanao in the Philippines; here the crew marooned Swan, and for another year cruised about the Malay seas—they touched at Tonquin and Cochin China, captured a few small Spanish vessels, and in the end decided to make south past Celebes and Timor to the vaguely known coast of New Holland.

The *Cygnet* sighted New Holland on 4 January 1688 in 16° 15′ S. lat. somewhere near the Lacepede Islands, and ran north along the coast to the entrance of King Sound, anchoring on the 5th in Cygnet Bay; here she was hove down and repaired, and Dampier resumed his usual pursuit of making the fullest possible notes about the country and its inhabitants. His description of the aborigines is well known: 'the miserablest people in the world. The Hodmadods of Monomatapa, though a nasty people, yet for wealth are gentlemen to these.' On 12 March the *Cygnet* sailed from King Sound by Christmas Island and the Sumatran coast to the Nicobars. There Dampier (who had long been tired of his companions) was marooned with two others—a few more deserting the vessel to join them—and the party bought a canoe and in spite of hurricanes managed to reach Sumatra; the *Cygnet* went off to Madagascar, and sank in St. Augustine's Bay. England was now Dampier's goal, which he attained by way of Tonquin, Acheen in northern Sumatra (1689), and Bencoolen in the south (1691), there boarding without leave a vessel (the *Defence*) bound for England and so, via the Cape of Good Hope, reaching home on 16 September 1691, three years after he left the *Cygnet* and eight after he started out.

In Bencoolen he had bought from a trader a certain 'painted prince' named Jeoly, a tattooed native of Mindanao, in the hope of making a living in England by exhibiting the curiosity; but he was compelled to sell the prince almost as soon as he arrived in London. For the next six years little is known about him except that during 1694 he was in Spain. In 1697 he brought out *A New Voyage Round the World*, dedicated

to Charles Montagu (afterwards earl of Halifax) the president of the Royal Society, and in the same year he was called as a witness in an enquiry about the proposed colonization of the Panama isthmus. The book stirred up two admiralty officials, Lord Orford and Lord Pembroke, to consider the possible advantages of a settlement in New Holland, which would lie on the flank of the Dutch Indies; and in 1698 Dampier was given the *Jolly* prize for an expedition to New Holland, New Guinea and the eastern Spice Islands. On his report that the prize-ship was quite unfit for the purpose he was given the *Roebuck* in exchange, and on 14 January 1699 sailed on his quest. The *Roebuck*, a vessel of 200 tons, was armed with 12 guns, manned with 50 men and boys, and commissioned in the navy, Dampier becoming a captain R.N.

He had intended to make his way out round Cape Horn and cross the Pacific in a latitude that would ensure his encountering some part of the still unknown east coast of New Holland. But the *Roebuck* was not in a condition to face the stormy seas of the Horn route, and its crew was cowardly and disinclined to run into bad weather unnecessarily. So Dampier took them south and east round the Cape of Good Hope, carefully avoiding on the way any port at which they might be tempted either to desert or to seize the ship. In the night of 1-2 August they struck soundings off the northern end of the Abrolhos group, and made north along the coast to an opening that Dampier named Shark's Bay, full of sharks, skates, and turtles, whose shores swarmed with iguanas and kangaroo-rats. Four days' search, however, produced no fresh water, and Dampier stood away north again past the archipelago named after him to Roebuck Bay, where on the 31st he at last came into contact with natives. But they were 'much the same blinking creatures' that he had seen 13 years earlier at King Sound; also there was no fresh water to be had, and scurvy was busy among the crew; so on 5 September he abandoned altogether further explorations on that coast, and made north for Timor, where he spent a restful three months among tropical surroundings. In December, having determined to investigate eastern Australia, he rounded the northern end of New Guinea, ran eastward from the Schoutens till he saw St. Matthias Island, skirted and rounded New Ireland under the impression that he was still on the New Guinea coast, and anchored in Montagu Harbour in New Britain: he had seen the 'Mother' rising from Blanche Bay, and the smoke from its minor craters, but was not attracted that way. Of the New Ireland and New Britain natives he saw a good deal, but could get nothing from them except coconuts and water, and had to procure pigs by armed force. Still coasting New Britain, in the evening of 24 March 1700 he sighted a very fine volcano, and was by it piloted through Dampier Strait: voyagers of to-day, however, will see no such sight, for Volcano Island has blown itself to pieces, diminishing in the last century from 2500 to 250 feet in height. The passage of the strait showed him that New Britain was really an island (he gave it its name) and the advent of the SE. trades made it a hazardous enterprise to push investigation farther south—or he might have passed New Guinea east-about and anticipated Cook; he let the trades take him back along the New Guinea coast, and on 26 April anchored off the western end of Ceram. Too little attention has been paid to Dampier's account of the New Britain group, which is very full and informative; his profile sketches of the coast, too, are useful to-day, and his observations on the natives are worth study by Australian administrators of the mandated islands.

On 3 July the *Roebuck* was in Batavia roads, characteristically asserting her dignity as a King's ship by demanding salutes from the Dutch authorities and from a British vessel at anchor there; but she was so ill-conditioned that on an overhaul the carpenter found her 'more leaky after he had caulk'd Her, then she was before,' and Dampier had to stay at Batavia until 17 October in order to make her fit for sea. She reached Cape Town on 30 December, St. Helena on 2 February 1701, and on the 23rd had to put in to Ascension Island with a leak too big to be stopped, even with slabs of the ship's beef. There she sank, with many of Dampier's books and papers; he and the crew came safe ashore, lived on the island till 3 April, and were then rescued and brought to England by H.M.S. *Anglesey* and the East Indiaman *Canterbury*.

Dampier's later life, though still adventurous and full of interest, was not concerned with Australian regions. His *Roebuck* voyage was disappointing to the admiralty, since it merely proved that New Holland would not serve their turn as an outpost against the Dutch; with his New Guinea and New Britain discoveries they were not concerned. Also, he had quarrelled with and somewhat bullied his second in command, a naval lieutenant of long standing, and a court martial decided that he could be no longer employed in the navy. Yet on 16 April 1703 he was again given a commission as captain to take two privateers into the South Seas. This was a fighting voyage, not one of discovery, and Dampier did nothing to his credit. One of his lieutenants was marooned and the other deserted; the mate of the second privateer (Alexander Selkirk by name, whose adventures were used by Defoe in his story of *Robinson Crusoe*) was marooned on Juan Fernandez, and Dampier ended the voyage as a prisoner in one of the Dutch East India settlements. He returned to England in 1707, found himself disliked and distrusted, and in August 1708 embarked as pilot aboard Woodes Rogers's privateer *The Duke*. This expedition had all the success the other lacked; rounding Cape Horn, it rescued Selkirk, raided the Spanish towns along the western coast of South America, captured a vessel carrying valuable cargo from Manila, crossed the Pacific to Batavia, and by way of Cape Town reached London again on 14 October 1711 with loot to the value of nearly £200,000. Dampier, however, profited nothing, for the prize-money was not distributed until 1719, and he died in London early in March 1715. Selkirk, it may be noted, was made second mate of *The Duke*, and was lieutenant in H.M.S. *Weymouth* when he died in 1723.

Dampier was a great man in his way, but his way was not that of command or of persistent endeavour. As a captain he failed again and again, both in tact and in discipline; as a seaman he was never more than one among the undistinguished crew. But as a close, accurate, and unwearying observer he was unequalled in his time, and possibly never surpassed. His charts and sketches are the best of their day, and some are still valuable; his drawings of birds and fishes are distinctly good; his writings are clear

and precise, and full of minor but nowadays specially interesting detail; his *Discourse of Winds* is spoken of by modern meteorologists as still a textbook worth study. He is best studied in his own writings, which in 1729 were published collectively (along with a few other narratives) by Knapton. Vol. i. is a reprint of his *New Voyage* (1697), vol. ii. contains his appendices on Indo-China and the Campeachy region and his *Discourse of Trade Winds, etc.* (1699); the *Voyage to New Holland, etc.* (1703) is in vol. iii., together with a *Description* of the isthmus of Panama by his shipmate Wafer (1702); in vol. iv. is Funnell's account of the privateering expedition of 1703-6, as well as four accounts of minor voyages. Dampier's reply to Funnell (who was a severe and not very competent critic of his work) was published in 1707, but is not included in the 1729 collection. It will be found at the end of John Masefield's edition of the *Voyages* (2 vols., 1906). There are also French and Dutch translations.

Dampiera, a genus of the family Goodeniaceae, consisting of herbs or shrubs mostly clothed with a heavy coat of cottony hairs, branched or star-shaped. Fifty-four species are endemic in Australia. The flowers are showy, purple, blue, white, or rarely yellow; calyx-lobes occasionally obsolete—when present they are small, often concealed under the hairy vestiture; corolla deeply slit in the upper part, but entire at the base; anthers cohering in a tube; fruit small, falling with the seeds still enclosed. In *D. Brownii* the hairs on the corolla are dark and plumed; *D. stricta* has angular branches and rust-coloured hairs on the flowers. Both favour the coastal sandstone.

Dangar, Henry (1798-1861), head of a notable New South Wales family, was born at St. Neot in Cornwall in 1798 and migrated to Sydney about the middle of 1821. He was at once appointed by Macquarie (at Oxley's request) assistant surveyor in the government service, and employed on field surveys. On 1 January 1826 he was sent to survey the area allotted to the Australian Agricultural Company at Port Stephens, and so came into contact with that company's officials. Consequently, when in 1827 Darling fell foul of him over his claim to some lands near Scone, and Dangar returned to England to protest against the governor's action, he was appointed surveyor to the company and returned to Sydney in that capacity at the end of 1829. In 1832 he settled finally at Neotsfield near Singleton, left the company's service in 1833, and sat as member for Northumberland in the old legislative council from 1845 to 1851. He died in 1861.

Of his sons, the second—Henry Carey Dangar—born at Port Stephens on 4 June 1830 and educated at the Sydney College and the university of Cambridge (M.A., 1857), was called to the bar in 1854, returned to New South Wales to take up a pastoral life, entered politics in 1874 as member for West Sydney, and was a member of parliament practically for the rest of his life (West Sydney, 1874-7; East Sydney, 1880-2; nominated to the legislative council, 1883). He died at Sydney on 25 April 1917. The third, Frederick Holkham Dangar, born at Port Stephens on 23 October 1831, preferred shipping to sheep-stations and founded the shipping firm of Dangar, Gedye & Co., which he managed until 1882. In that year he disposed of all his Australian interests and retired to London, where he died on 26 March 1921. He was especially interested in the training of officers for the British mercantile marine, and had a share in the well-known training-ships *Medway* and *Port Jackson*. Albert Augustus Dangar, the fifth of the brothers was probably the best-known of all. Born at Neotsfield on 8 June 1840 and at first inclined for sea service (he spent three of his boyhood years at sea), he was in 1858 placed on Gostwyck station near Armidale (which had been acquired by another brother, William Dangar, from E. G. Cory in 1834) to study stock-breeding, and in 1863 took charge of that and other properties as manager for the family. When the brothers divided the Dangar lands among themselves, A. A. Dangar took Mooki and another station, leased Gostwyck from a brother, and set himself to breeding merinos, long-woolled Devons, shorthorn cattle, and Suffolk Punch horses. Both as a breeder and as a business man he was uniformly successful, and, though never in politics, took a prominent part in public life; possibly he is most widely remembered (*a*) by the part he played as president of the Pastoralists' Union in the maritime strike of 1890, and (*b*) by his gift of £10,000 to a fund for providing a 'Dreadnought' battleship as a gift from Australia to Britain in 1909, which was afterwards diverted to the support of an immigration scheme for boys between 15 and 20. He also contributed largely to patriotic and other funds in connection with the South African war. He died at Baroona near Singleton on 5 April 1913.

Henry Dangar's brother Thomas settled in the twenties at Maitland, and about 1837 moved to Invermein near Scone. He was a member for the Upper Hunter from 1861 to 1864. His son, Thomas Gordon Gibbons Dangar, born at Sydney on 17 November 1829 and educated at the Sydney grammar school, settled in 1849 on the Namoi near Wee Waa, and from 1865 to 1880 sat in the assembly as member for the Gwydir, and for the Namoi (practically the same constituency under a new name) from 1880 till his death, with one slight intermission. He was a persistent advocate of a scheme for locking the Darling-Barwon river, and succeeded in having vessels brought up as far as Walgett. He died in Sydney on 4 July 1890.

Another family of Dangars, also Cornish but hailing from Bodmin and apparently quite unconnected with the family discussed above, was founded at Port Macquarie (moving later to Kempsey) by W. S. Dangar in 1834. The most notable member of this family was O. O. Dangar, born in 1842, who from 1889 to 1893 sat in the assembly for the Macleay.

Daphnandra, a genus of the family Monimiaceae, consisting of trees; the three species are endemic in Australia. *D. micrantha* (Satinwood) is a handsome tree of moderate size, extending from New South Wales to Queensland. It has a fragrant timber, used for packing-cases, but rather soft for most purposes. *D. repandula* is limited to Queensland. The bark has a transient bitter taste; infusions from it are rich in alkaloids and very poisonous, the action affecting the heart. The extract retards the development of septic germs, and will deodorize putrid meat.

Darley, Sir Frederick Matthew (1830-1910), born on 18 September 1830 in Dublin, and educated at the royal school of Dungannon and at Trinity College, Dublin (B.A., 1851),

was in January 1853 called to the Irish bar and went the Munster circuit. In 1861, when on circuit, he met Sir Alfred Stephen, who advised him to come to Australia. Leaving England in January 1862, he was admitted in June to the bar of New South Wales (Q.C., 1878). In September 1868 James Martin nominated him to the legislative council, of which he remained a member for 18 years; in November 1881 he succeeded John Robertson as vice-president of the executive council in the third Parkes ministry, and held office until the ministry was defeated in January 1883. Never a strong partisan, his most important political work was connected with the passage through the council of equity, divorce, companies, and criminal law amendment measures. In 1884 he and his brother-in-law Sir Peter Scratchley were appointed a commission to enquire into the defences of the colony. On the death of Sir James Martin in November 1886 Darley was offered the chief justiceship, but declined it; when Julian Salomons accepted and then resigned it, W. B. Dalley persuaded Darley to reconsider his refusal, and he was sworn in on 29 November. In 1891 he was made lieutenant-governor on the resignation of Sir Alfred Stephen, and in virtue of this appointment was five times acting-governor. In 1902, while on a visit to England, he was made a member of the South African war commission. He resigned his offices in 1909, went to England, and died there on 4 January 1910. (Kt. Bach., 1887; K.C.M.G., 1897; G.C.M.G., 1901; P.C., 1905.)

Darling, Sir Charles Henry (1809-1870), born in 1809 at Annapolis Royal in Nova Scotia and educated at the Royal Military College, Sandhurst, joined the army on 7 December 1826 (ensign, 1826; captain, 1839), and in 1827, coming to Australia with a detachment of his regiment (the 57th), was made assistant private secretary to his uncle Ralph Darling—then governor of New South Wales—becoming in 1830 his military secretary. When Governor Darling returned to England and the regiment was transferred to India, young Darling obtained permission to enter the senior department of the Royal Military College, and from there was appointed to the staff of Sir Lionel Smith, serving as his military secretary in the West Indies from 1833 to 1839. In 1841 he retired from the army to settle in Jamaica, and in 1843 was appointed director of immigration and adjutant-general of militia; he was also a member of the local legislative council, and in 1846-7 acted as secretary to the governor. In 1847 he was appointed lieutenant-governor of St. Lucia, and in 1851 lieutenant-governor of the Cape Colony to function during the absence of Sir George Cathcart on military duty in the eastern province. From May to December 1854, Cathcart having gone to command a division in the Crimean war, he administered the colony, and so presided at the incoming of parliamentary government. Before he actually left the Cape, he was nominated governor of Antigua and the Leeward Islands; this appointment he never took up, being sent on his return to England to administer Newfoundland, in which he inaugurated responsible government. From March 1855 to February 1857 he was governor of that colony; then he was promoted to the governorship of Jamaica, Honduras and the Bay Islands; and on 11 September 1863 he was transferred to be governor of Victoria. Here he was comparatively unsuccessful. Taught by two previous experiences that under modern conditions a governor must interfere as little as possible with the local politicians, he overdid non-interference and allowed the McCulloch ministry to tack a protectionist tariff on to the appropriation bill. The council, which under the constitution could not amend a money bill, rejected the whole bill again and again; a deadlock ensued, and to obtain funds for paying the public service and other government creditors McCulloch (q.v.) devised a scheme under which a bank lent the government money to pay its debts, then sued for the return of it, procured a judgment against the State, and was repaid under the governor's warrant. The council naturally protested, and petitions were sent to England against this autocratic procedure, but McCulloch dissolved the assembly and appealed to the electors, who sent him back with a much increased majority. Meanwhile duties under the rejected tariff had been and were collected, in spite of a supreme court judgment that they were illegal; and for allowing this and the other evasions of law Darling was sharply rebuked by the British government. His reply to the rebuke, including as it did a bitter attack on the personal character of certain councillors and a declaration that, if they were ever members of a ministry, he should receive their advice 'with doubt and distrust' compelled the British authorities to recall him. Cardwell in April 1866 made this decision, and it was confirmed by his immediate successor Lord Carnarvon. Darling's departure from Melbourne was characterized by exceptionally vivid demonstrations of popular sympathy, while the assembly in a parting address thanked him for having saved the colony from anarchy, and offered a gift of £20,000 to Lady Darling to compensate him for his enforced removal. Darling, of course, could not accept this without special permission from the colonial office. The assembly requested permission; Lord Carnarvon replied that it was impossible while Darling remained in the service; Darling thereupon resigned, and McCulloch 'tacked' the vote to an appropriation bill; the council rejected the whole bill, as before, and another election confirmed McCulloch's action. Then the British government again took a hand, directing the new governor (Sir J. H. Manners-Sutton, for whom see Canterbury, Viscount) not to allow tacking. McCulloch promptly resigned, the assembly refused to grant supply to his successor, and the governor had to recall him. Before his actual reappointment the problem had been otherwise solved. Darling, withdrawing his resignation, was granted by the British government a pension of £1000 a year from the date of his recall, and therefore intimated to the Victorians that the proposed gift was unnecessary. But when he died two years later (on 25 January 1870) the Victorian parliament unanimously voted a similar pension to his widow. (K.C.B., 1862.)

Darling, Joseph, born at Adelaide on 12 November 1870, came into prominence as a cricketer when at the age of 15 he made a score of 252 in a school match. On leaving school he took up farming, but in 1883 returned to Adelaide and in 1885 played with a South Australian fifteen that met the Australian team of 1886 (see Cricket). In 1893 he began to play for his colony, and from 1895 to 1906 was a member of every Australian team that went to England, captaining those of 1899, 1902, and

1905. He also took part in every test match played in Australia between December 1894 and January 1902, and in 1901-2 captained the Australians in the test matches at Sydney. Against Stoddart's English team of 1897-8 he scored three centuries in the five test matches. His highest score in test cricket was 178 (at Adelaide in January 1898), and his average for 55 innings 30.79. His scores in first class matches aggregate 10,723 runs, an average of 34.2. He is one of the greatest left-handed batsmen Australia has produced, and his 160 against England at Sydney in 1898 is probably one of the finest recorded exhibitions of hard hitting against great bowlers on a good wicket.

Darling, Sir Ralph (1775-1858), born in 1775 and in his early youth employed in the custom-house at Grenada in the West Indies, joined the army in 1793 (ensign, 1793; lieutenant, 1795; captain, 1796; major, 1800; lieutenant-colonel, 1801; colonel, 1810; major-general, 1813; lieutenant-general, 1825; general, 1841), and served in the West Indies—with one short interval—until 1802, taking part in the capture of Dutch Guiana and the Danish and Swedish islands. Returning to England in 1802 to take up an administrative appointment, he was sent to India with his regiment (the 69th) in 1805, but came back in 1806 and was a member of the staff at the horse guards until 1818. During these years he saw active service twice—with the 51st regiment under Sir John Moore in the expedition of 1808 that ended at Corunna (for which he received the gold medal), and in the Walcheron expedition of 1809. In 1818-23 he was in command of the British garrison in the Mauritius, and for the first 18 months of that term acted as governor, incurring much local displeasure by his success in putting down the slave-trade. This command ended his military service, which was distinguished for good staff work rather than for achievement in the field. Soon after his return to England he was invited to take over from Sir Thomas Brisbane the administration of New South Wales. With his accustomed thoroughness Darling spent the time that elapsed between his appointment and his departure from England in studying all available documents relating to New South Wales, and sent his private secretary, Henry Dumaresq (q.v.), in advance to collect local information on the conditions of the colony. Early in December 1825 Darling arrived in Hobart, proclaimed the separation of Tasmania from New South Wales, and instituted a separate administration under a lieutenant-governor. He then proceeded to Sydney. It was his intention to win respect for his administration by impartiality, and to align himself with neither of the existing political parties. Unfortunately for his purpose, he soon became involved in an acrimonious controversy with the independent press. There was considerable unrest in the colony. A group of native-born Australians led by W. C. Wentworth (q.v.), jealous of officials and 'exclusives' and eager for position and power, were demanding freer political and judicial institutions; to this end they were seeking the support of other discontented groups —emancipists, new settlers with small capital, soldiers, convicts, and any others who felt they had a grievance against the government.

The year 1826 was one of severe economic depression, following on a period of over-speculation in land and stock, and the general discontent was focussed by an untoward incident that enabled the local leaders, through the independent press, to direct a bitter attack against Darling. The troops had come to believe that a convict's life was preferable to that of a soldier, and on different occasions soldiers had deliberately committed crimes in order to be convicted. Darling, who from the beginning of his term had tightened the bonds of both military and convict discipline, considered this conduct a grave breach of military honour; when two soldiers—Sudds and Thompson by name—in 1826 committed larceny in order to be convicted and so dismissed from their regiment (which was under orders for India), he determined to make an example of them. He commuted their sentence of transportation to work with the road gangs, and ordered them to be publicly degraded and loaded with spiked iron collars. Gauged by the standards of the period, the punishment was probably not over-severe, but unfortunately Sudds died a few days after the public degradation. Immediately the disaffected politicians seized upon the incident, and Wardell (editor of the *Australian*) and Hall (of the *Monitor*) launched a bitter attack on the governor. He, resenting the personal attack, and no doubt fearful of growing disaffection among the convicts, decided to bring into force regulations for the control of the press which had been suggested to him by the colonial office before his departure from England. But his efforts to introduce a drastic licensing measure, and to impose stamp duties, were frustrated by Francis Forbes (q.v.), whose duty it was as chief justice to decide whether a proposed measure was repugnant to the laws of England. Forbes objected to both these measures as taking away the natural right of a British subject to free speech. Darling then attempted to control the independent press by a measure relating to seditious and blasphemous libels; but this, though it received Forbes's certificate, was disallowed by the colonial office. Darling was therefore thrown back upon a policy of prosecutions, and during 1829 the supreme court was principally occupied with libel actions that led to much ill-feeling between prominent individuals in the colony. Among other somewhat questionable methods intended to suppress adverse criticism, he attempted to withdraw convict servants assigned to the editors of opposition papers. The press, however, remained free, and E. S. Hall, who during the controversy had been frequently imprisoned for libel, was —with the assistance of Joseph Hume, a radical member of the British house of commons— largely instrumental in effecting Darling's recall.

Though the press controversy occupies so large a space in the history of Darling's administration, the very real political, judicial, and economic progress made in the colony during that period should not be ignored. Darling opposed the demands of Wentworth's party for a legislative assembly, as unsuited to the conditions of the colony; but he was prepared to advocate an enlarged council, initiation of legislation by its members, and election of the unofficial members. By an act of 1828 (for which see Constitutions) important advances were made towards political freedom. The unofficial membership of the council was increased; both the right of the governor (or king) in council to legislate against the wish of the council, and the virtual veto exercised by the chief justice over legislation, were greatly modified; private members were permitted to initiate mea-

sures, and the oath of secrecy was withdrawn. In addition to these constitutional changes the colonial office had already, by instructions issued in July 1827, changed the financial basis of the administration. A differentiation was in future to be made between expenditure incurred in the civil administration of the colony—which must be met out of colonial revenue—and that incurred in maintenance and control of the convicts, which would be met by the British treasury. During Darling's governorship, too, an approximation was made to modern judicial practice. The act of 1823 had provided for trial by jury in civil cases, when both parties concurred. Under the act of 1828 trial by jury could be granted by the court at its own discretion on the application of one party. Power was also given to the governor in council to extend the system of trial by jury in criminal cases. The first trial by a civil jury in the supreme court was allowed in 1830.

A radical change was also made in the system of land alienation. The activities of the Australian Agricultural Company in 1825-6 had led to a period of over-speculation that ended in a financial crisis. Darling created a land board to examine the claims of each applicant for land, to pick out *bona fide* settlers, and to allow them 640 acres for every £500 invested—a method that was strongly opposed by the poorer colonists. His proposal for a land pension scheme for loyal officials was rejected by the colonial office, but he was frequently accused of partiality in making land grants to his supporters. In 1831 the land grant system was abolished by instructions from London, and a minimum sale-price of 5s. per acre was fixed.

Darling was further responsible for many departmental reforms of material value to the colony. He facilitated inland communication by opening up good roads, substituted a department of customs for the old collection of import duties by a 'naval officer,' sanctioned the improvement of the water-supply for Sydney by Busby's bore (see BUSBY, JOHN), reorganized the post office and established an inland post, reformed the currency, and made arrangements for lighting the city streets. He deserves high praise, too, for encouraging the explorer Sturt (q.v.) in spite of the hostility of Mitchell, the surveyor-general. To his term are also credited the opening up of the Moreton Bay district by Patrick Logan, the discovery of the Darling Downs by Allan Cunningham, and the tracing of the Brisbane River to its head by Edmund Lockyer. While Darling was thus encouraging inland exploration, he was at the same time urging on the colonial office the necessity of laying claim to the whole of Australia, his commission giving him no control over the western coast; and in his time King George's Sound was occupied, and a settlement made at Swan River.

Darling's best service to the colony was his reorganization of the administrative departments, though he spoiled much of his work by too close attention to detail. But he was never popular; Forbes undermined the confidence of the British government in his capacity; charges were continually made against him by disaffected colonists; and with the fall of the Tory government in 1830 his recall was inevitable, and came in March 1831.

After his return to London his time was occupied in replying to his numerous critics, and in preparing his defence before a select committee of the house of commons which was appointed in 1835 to investigate the charges of misgovernment made against him. By this committee he was acquitted of blame in the Sudds-Thompson affair, and no evidence was given in support of other charges. William IV was thus able to confer a knighthood on him in recognition of his long service, but he was not again employed. He died at Brighton on 2 April 1858. (G.C.H., 1836.)

Darling Lily. See AMARYLLIDACEAE.

Darling Pea, popular name of several species of *Swainsona*. This is a genus of the family Leguminosae, consisting of herbs which, with the exception of one New Zealand species are endemic in Australia. The plants have fern-like leaves, showy blue or pink to reddish pea-shaped flowers, and thin, inflated pods. Sheep which habitually eat these herbs separate from the flock, wander listlessly about, eventually reach a stage of delirium and frequently injure themselves by jumping over imaginary obstacles. The most dangerous species are *S. Greyana, S. luteola, S. galegifolia,* and *S. coronillifolia.*

Darter or **Snake-bird,** a large aquatic bird (*Anhinga novae-hollandiae*) the only Australian representative of the family Anhingidae. Other members of the genus are found in the warmer parts of America, Africa, and southern

Darter.

Asia. The Australian darter frequents rivers and swamps throughout the continent, and is also found in New Guinea. In general appearance it resembles its relatives the cormorants, but has a very long, slender neck which, when the body is submerged while swimming, resembles a snake rising from the water; hence the name 'snake-bird,' often applied to it. The anatomy of the neck is remarkable, the lower vertebrae being set irregularly and the corresponding muscles specialized. When swimming beneath the water, the bird keeps its neck bent until it comes within striking distance of a fish; then the neck is suddenly straightened by the action of the specialized muscles, and the fish impaled on the sharp bill.

Darters are comparatively rare birds in southern Australia, but on some occasions considerable numbers appear in districts where they are not generally seen. They are sociable, and breed in colonies, constructing nests of sticks in trees growing in swamps. W.B A.

Darts, fishes belonging to the widely distributed genus *Trachinotus*; several occur on the tropical coasts of Australia, and some extend southwards in warm currents. They resemble their allies the trevallies (Carangidae) in general form, but are covered with distinct and brilliant silver scales. They are very swift swimmers, and their vertical fins are produced into acute lobes, on account of which they are also known as swallow-tails. One species (*Trachinotus anak*) may attain a length of four feet; it is very destructive to oyster beds, moving over them in schools of 50 to 100 individuals, and devouring large quantities of the shell-fish. It has no teeth in the jaws, but its throat is provided with powerful crushing plates. A.R.McC.

Darvall, Sir John Bayley (1814-1883), born in Yorkshire in 1814, educated at Eton and Cambridge (B.A., 1833; M.A., 1837), and called to the bar from the Middle Temple in 1838, migrated the next year to New South Wales to practise his profession in Sydney. Entering local politics, he was in 1844 nominated to the legislative council, but in 1848 resigned the nominee position and was elected to the council first by Bathurst (1848-51) and then by Cumberland (1851-6). Consistently with that resignation, he opposed Wentworth's scheme for a constitution because it included a non-elective upper house. After the introduction of responsible government he was returned to the new assembly by the North Riding of Cumberland (1856-7), the Hawkesbury (1859-60), East Maitland (1863-4), and West Sydney (1864-5) accepting nomination to the council during the interval 1861-3. He was solicitor-general in the Donaldson ministry of 1856, and held the same office and that of attorney-general in the Parker ministry of 1856-7. Sir George Reid eulogizes his 'accomplished wit, which could reach heights of graceful eloquence and depths of abusive satire with equal facility and finish.' In 1850 he was appointed a senator of the university of Sydney, and in 1851 refused the offer of a judgeship in Victoria. In 1865 he abandoned politics, returning two years later to England, where he died on 28 December 1883. (C.M.G., 1869; K.C.M.G., 1877.)

Darwinia, a genus of the family Myrtaceae, consisting of heath-like shrubs with small opposite or scattered leaves. The genus is endemic in Australia, 18 out of 23 species being confined to Western Australia. The flowers are small, white, or greenish; calyx-tube cylindrical, bell-shaped, or hemispherical, 5- (rarely 10-) ribbed; petals 5, entire; stamens 10, alternating with staminodia, and shortly united at the base in a ring. Several species contain a highly perfumed volatile oil; but there is considerable difficulty in their propagation, as they rarely produce perfect seeds.

Daucus, a widely distributed genus of the family Umbelliferae, consisting of herbs. *D. carota* is the culinary carrot. *D. brachiatus* (Native Carrot), a slender herb found in all the States, is a useful stand-by to the western pastoralist, its deep tap-root enabling it to withstand drought. Sheep are very fond of it, and thrive wonderfully on it where it is plentiful; in dry periods the hungry ones scrape the roots out of the ground with their hoofs. The bristly fruits, locally known as carrot burrs, are slightly injurious to wool.

Davenport, Sir Samuel, (1818-1906), born at Shirburn in Oxfordshire on 5 March 1818, in 1842 migrated to South Australia and, with his brother Robert, was the first to farm land in the Macclesfield district, where another brother (George Francis) had purchased a 'special survey' in 1839. The fluctuations incidental to pastoral life induced him in 1845 to cross the Murray and take up land near Beachport on Rivoli Bay, of which district also he was a pioneer. In May 1846 Colonel Robe nominated him to a seat in the legislative council, but he opposed Robe's policy both on mineral royalties and on state aid to religion, and had to resign. In 1855, however, Sir R. G. MacDonnell again nominated him, but he resigned in August 1856, and in March 1857 was elected to the new council, retaining the seat until August 1866. During 1857 he was commissioner of public works in the Finnis (March to August) and Torrens (September) ministries. Politics, however, was not his chief interest; his real value to the colony was as a developer of its resources. He pioneered settlement not only at Macclesfield and Rivoli Bay but in the north and north-east also. In 1859 he accompanied Warburton in his explorations between Streaky Bay and Lake Gairdner. At Beaumont in the hills above Adelaide he grew vines and olives, and encouraged the growth of mulberry trees for silkworm culture. He was frequently chosen to represent his colony at international exhibitions, among them the London of 1861, Philadelphia of 1876, Sydney of 1879, Melbourne of 1880, and Colonial and Indian (in London) in 1886. He was the first president of the South Australian branch of the Royal Geographical Society, as well as president for 7 years of the local agricultural society, and for 15 years of the Adelaide chamber of manufactures. He died on 3 September 1906. (Kt. Bach., 1884; K.C.M.G., 1886.)

Davey, Thomas, of whose youth nothing is known except that he was a protégé of Lord Sandwich and that his father was a personal friend of the first Lord Harrowby, obtained a commission in the marines in 1778 (2nd lieutenant, 1778; 1st lieutenant, 1780; captain-lieutenant and captain, 1795; major, 1809; lieutenant-colonel in army, 1812, colonel—local for New South Wales—1813; on half-pay, 1814), and on 30 November 1786 volunteered for service in the guard intended to accompany Phillip to Australia. No sooner, however, had he discovered the nature of the settlement than he applied for relief at the expiration of three years, as he was entitled to do under his original agreement; and in December 1792 he returned to England, reverted to the main body of the marine corps, and served at Trafalgar. In 1810, news of the death of Colonel Collins having reached London, Davey applied for the vacant lieutenant-governorship of the Derwent settlement, and brought the Harrowby influence to bear; consequently, when in 1811 it was decided to bring the whole island under a single lieutenant-governor, Davey was appointed—partly, it would appear, in order that from his much increased pay he might be able to refund to the corps the large amount by which his accounts as paymaster were short. Bathurst warned Macquarie privately that his financial honesty was doubtful—fair evidence that the appointment had been made by influence outside the colonial office; and Macquarie in 1817, when Davey was recalled, wrote openly that 'it would have saved a great deal of Money to the Crown, had Government given a Pension of Two or Three Hundred per Annum

to Colonel Davey, instead of sending him out as Lieutenant-Governor.'

Though his commission was dated 1 September 1811, he did not leave England until 4 June 1812, and stayed in Sydney for nearly four months after his arrival there on 25 October. Macquarie was unfavourably impressed by him; he seemed honest and well-meaning, but was dissipated, volatile, and easily imposed on; still for a year or two his public conduct was 'pretty correct.' In 1815, however, his profligacy and drunkenness had begun to affect the public service (among other charges is one that he had connived at the smuggling of spirits), and Macquarie urged his recall. Davey stoutly denied the charges, and bombarded Harrowby with detailed attempts at refutation and counter-charges that involved both Macquarie and his own successor Sorell. The general situation, however, was too clear to admit of condonation, whether or no any particular charge was untrue; private profligacy, wrote Bathurst, could not be overlooked in the officer commanding a reformatory, and Davey must go—though 'in the way least hurtful to his Feelings and to those of his Family.' Accordingly on 27 November 1816 Macquarie notified him of his recall and offered him an additional grant of land in Tasmania as compensation; Davey considered the offer insufficient, and after handing over the colony to Sorell on 9 April 1817 went to Sydney and for a year fought hard to get the grant increased and transferred to the mainland. He then returned to Tasmania, tried to farm his grants and failed, and on 11 May 1821 left Hobart for Sydney and England. About the same time his land-grants were finally settled at 4000 acres in Tasmania (including 200 at Newtown, close to Hobart) and 2000 in the Illawarra district of New South Wales. He died in England on 2 May 1823.

The actual value of Davey's work in Tasmania is much disputed, and the usual view is that he was an uncouth ruffian of whom the colony was well rid. This is most unjust to him. His private life is indisputably beyond excuse. His official landing in the colony—'the weather being warm, he carried his coat on his arm'—may have been undignified. But his administration of public affairs was on the whole marked by common sense; he threw open the port of Hobart and encouraged farming, thus providing the settlement with two wide avenues to prosperity; he did as much building as his limited labour supply would allow; and his proclamation of martial law throughout Tasmania on 25 April 1815, though illegal and repudiated in severe language by Macquarie, was the one measure taken against the bushranging gangs of the time that really checked them.

David, Sir Tannatt William Edgeworth, born on 28 January 1858 at St. Fagans near Cardiff in Wales, and educated at Magdalen College school and New College, Oxford (B.A., 1880; Hon. D.Sc., 1911; Hon. D.Sc., Manchester, 1919), in 1882 proceeded to New South Wales to take up an appointment as assistant geological surveyor in government employ. In 1883 he surveyed the tin-fields of the New England district, and in 1886 the coal-bearing strata of the lower Hunter valley; during this work he discovered the hitherto unsuspected existence of important coal-seams west and south of Maitland, and a large area there was reserved by the government for coal-mining and subsequently became the great Maitland field (see Coal). In May 1891 he was made professor of geology and physical geography in the university of Sydney. He at once became a leader in the scientific world of Australia, was elected in 1896 to the presidency of the Royal Society of New South Wales, in the same year joined the coral research committee of the Royal Society of London, and in 1897 led an expedition to Funafuti in the Ellice group to superintend the putting down of a bore to ascertain the actual structure of coral reefs. This bore, which was carried to a depth of 1114 feet, confirmed the theory of Charles Darwin about reef-formation. In 1899 he was awarded the Bigsby medal by the Geological Society of London. In 1900 he was elected a fellow of the Royal Society of London. In 1898-1905 Professor David devoted himself to his university duties indefatigably, employing any spare time in the investigation of evidence for a glacial period in Australia. For this and similar work the Australasian Association for the Advancement of Science in 1909 gave him the Mueller medal. In 1906 he explored for geological purposes the Deccan (India) tableland at the head of the Godaveri River, and, after attending the international geological congress in Mexico as a delegate from Australia, investigated the effects of the San Francisco earthquake. Towards the end of 1907 he joined the Shackleton expedition to the Antarctic (see Antarctica), intending merely to accompany it to South Victoria Land and return with the *Nimrod*; but on arrival at the base he decided to see the enterprise through, and became the unquestioned leader in its scientific work. He led the climbing party in the first ascent of Mount Erebus, and another to ascertain the exact site of the south magnetic pole, which he reached on 16 January 1909. In 1914 he was awarded by the Geographical Society of France the Maltebrun medal, for work done in collaboration with R. E. Priestley on the geology of Antarctica, and in 1915 received the Wollaston medal from the Geological Society of London.

About the middle of 1915 the Australian government decided to send a mining corps to the front, and David energetically aided in recruiting and organizing it, accompanying it in February 1916 as major in charge of the technical headquarters staff. When in May the corps reached Hazebrouck, it was reorganized as three separate companies, and David was absorbed into general headquarters as chief geologist to the British army, supervising the practical application of geological knowledge to tunnelling, water-supply, and the locating of deep dug-outs throughout the British sphere of operations. He held this position till the war ended, winning the D.S.O. in 1918, and returning in May 1919 to New South Wales to resume his work at the university. In 1917 the Royal Society of New South Wales awarded him the Clarke medal, and in 1924 he was elected a corresponding member of the Geological Society of the U.S.A., and in the same year resigned his professorship and retired on a pension, devoting himself thenceforth to research work. In 1925 he was elected an honorary member of the Geological Society of Belgium, and a foreign member of the Royal Bohemian Science Society of Prague. (C.M.G., 1910; K.B.E., 1920.)

Daviesia. See Leguminosae.

Davis, Henry Charles (1815-1854), born at Usk in Monmouthshire on 18 May 1815, edu-

cated at Downside and ordained priest on 8 November 1840, was for some years prefect and —since he had fine musical taste—precentor of Downside, and afterwards missioner in charge of the parochial district surrounding the college. On 24 September 1847 he was by papal brief appointed to the bishopric of East Maitland in New South Wales, the intention being that he should act as coadjutor to Archbishop Polding in Sydney—and in fact he never visited the town from which he took his title. He was consecrated in August 1848, and arrived in Sydney on 8 December, taking up at once his duties as coadjutor—which were concerned especially with the educational and business administration of the diocese—and adding to them the particular care of church music. He almost rivalled Dr. Polding himself in inspiring the admiration and love of his co-religionists. Further, his zeal for and skill in education won for him the close friendship of Dr. Woolley, the Anglican principal of the university of Sydney, of which Dr. Davis was a senator from 1850 to 1854. His health, however, never good, gradually grew worse during his life in Sydney, and he died on 17 May 1854.

E. M. O'B.

Dawes, WILLIAM, son of an admiralty official at Portsmouth, joined the royal marines as a second lieutenant in 1779, and seems to have very soon distinguished himself as a scientific observer and astronomer. When in 1786 it was decided to send an expedition to New South Wales, Dawes (then stationed at Portsmouth) volunteered for the service, and Dr. Maskelyne (the astronomer royal) recommended that he be put in charge of the observations of a comet which was expected to be first seen in southern latitudes during 1788. Ross's detachment of marines being complete, Dawes was attached to the marines in the *Sirius*, but in July 1788 was transferred by Ross to the marine force on guard duty in place of William Collins. About this time he was building on Dawes Point—which he called Point Maskelyne—the first observatory in Australia (see ASTRONOMY), and it remained in his charge until his departure; Maskelyne in 1791 gave it a transit instrument. Dawes also acted as engineer officer, designing defences for the port, a service for which he had been specially recommended by Lord Grenville, then home secretary. In December 1789 he led an exploring expedition across the Nepean (which had just been discovered by Tench) to a hill which he named Mount Twiss—probably the ridge beyond Linden; like the other Blue Mountain explorers of those days, he spent most of his time in descending precipices and climbing up the opposite cliffs, instead of keeping on the ridge, as the Blaxland party did in 1813. Another expedition in August 1790, with Tench and Hill, merely tangled him up in the rough country along the Warragamba. In 1788 he had applied for leave to remain three years in the colony, and in 1791 would have taken advantage of Grenville's recommendation and prolonged his stay, but for an unfortunate quarrel with Phillip. In December 1790 Phillip ordered out a search party to hunt down an aboriginal who had wounded his convict gamekeeper, and either capture or kill six others as a warning. Dawes at first refused to take part in such an expedition, but after a consultation with Richard Johnson, the chaplain, reconciled his conscience to the duty. On returning, however, he told Phillip he was very sorry for having gone, and would never undertake such work again. This naturally angered the governor, who regarded it as a reflection on his humanity; Dawes refused point-blank to withdraw what he had said, and it became impossible for him to serve longer in the colony. At the end of 1791, therefore, he returned to England, with the intention of revisiting New South Wales and settling there as a farmer and teacher of aborigines. William Wilberforce, however, intercepted him and procured him the governorship of Sierra Leone. Two years' hard work there (1792-4) so impaired his health that he could no longer perform his official duties, and Wilberforce tried to get him another appointment in Australia, preferably as superintendent of schools; but Dawes preferred to try West Africa again, and even sacrificed his half-pay to do so. He came back from Sierra Leone in 1796, and then disappeared into private life—so that Hunter in 1798, needing an engineer, had to suggest that 'if Mr. Dawes could be found' he would suit very well. In 1799 he was a witness before a house of lords committee on the slave trade, and in 1800 went for the third time to Sierra Leone, but was back in England by 1807. His later career is unknown in detail; he settled in the West Indies, and it was believed for many years that he died at Grenada on 14 April 1819—at which date a Lieutenant Dawes, R.N., did die there. But in the Mitchell Library at Sydney there is a memorial addressed by him to the colonial office from Antigua on 1 December 1826, recounting his services and applying for back pay that Phillip had promised him.

Dawes was an exceptional man for his time. His scientific ardour—Mrs. Macarthur notes that 'he is so much engaged with the stars that to mortal eyes he is not always visible'—and his humanitarian principles, which in New South Wales drove him to technical mutiny and in Sierra Leone undermined his health, were qualities uncommon among soldiers (or even private people) of the early settlement. His name is commemorated in Dawes Point, Port Jackson, the site of his observatory and of his first defence works.

Dawson, ANDREW (1863-1910), usually known as Anderson Dawson, was born at Rockhampton in Queensland on 16 July 1863, received but a meagre education, and was in turn grocer, mining prospector, and amalgamator. He was the organizer and first president of the miners' union of Charters Towers, and in 1893 was returned by that constituency to the Queensland legislative assembly. Being an effective debater, he soon became prominent in the parliamentary Labour party, and on 1 December 1899 formed the first Labour ministry that held office in Queensland—or in Australia; it was notable as including Andrew Fisher and William Kidston, but lasted only till the 6th of the month. In 1901 Dawson was elected to the federal parliament as one of the six senators from Queensland; he was minister of defence in the Watson ministry from April to August 1904, was defeated at the election of 1906, retired from politics, and died at Brisbane on 20 July 1910. Though his name is given as Anderson Dawson in parliamentary returns the registers of his birth and death show that his Christian name was Andrew.

Deakin, ALFRED (1856-1919), born on 3 August 1856 and educated at the Melbourne grammar school and the university of Melbourne, was called to the Victorian bar in 1877, but almost immediately abandoned his profession for journalism and politics. He joined the staff of

the *Age* and the *Leader*, establishing a firm friendship with David Syme, who in 1879 recommended him to the electors of West Bourke. In the next 18 months he fought four elections for this constituency, winning the first against Robert Harper, losing the next two, and in July 1880 heading the poll. He represented it uninterruptedly until 1889; on its subdivision in that year he was returned for Essendon, and retained that seat until, in 1900, he left State for Federal politics. Entering the Victorian parliament as a supporter of Graham Berry, his eloquence so marked him out that in 1883 Berry took him into the Service-Berry coalition of that year, and when those two leaders retired in 1886 the coalition was maintained under Gillies and Deakin for another four years. His main interest during this period was the use of irrigation to extend settlement north of the main divide. In 1884 he was made chairman of a commission on the subject, and in 1885 visited the United States and Mexico to study irrigation methods; in California he met the Chaffey brothers (q.v.), and from this meeting originated the settlement at Mildura. Soon after his alliance with Gillies his report took practical shape in an irrigation act, followed by several water-supply acts, which gave the State control over all sources of water-supply, authorized the construction of 'head works' (reservoirs, etc.) out of public funds, and permitted the formation of district irrigation trusts to which money might be advanced for the construction of channels and other agencies of distribution. Here, unfortunately, Deakin's one serious defect as a politician intervened to produce something like a disaster. He retained to the end of his life the underlying belief that all men were as highminded and scrupulous as himself, and that precautions against dishonesty or wilful negligence were unnecessary. Consequently no certain provision was made against the carelessness or maladministration of the water trusts, and in a few years the government found itself saddled with a large number of bad debts, and was compelled to write off much of the money it had advanced. Nevertheless Deakin's policy, though extremely costly, was of great benefit to Victoria, and has enabled that State to employ usefully an exceptionally large proportion of its area.

In 1887 Deakin was chosen (with Service, Berry and Lorimer) to represent the colony at the London conference of that year. His oratory and culture made a great impression on English public men, and his candid criticism of the colonial office and the British prime minister (Lord Salisbury) set a much-needed example to other Australian delegates, and for the first time asserted the position of the self-governing colonies as integral parts of the Empire rather than dependencies of the mother-country. Before returning to Australia he visited Italy and Egypt, and studied the irrigation methods of those countries. In 1890 the Gillies ministry after several reconstructions was defeated, and the *Age* commissioned Deakin to visit India and study irrigation there; this tour resulted in the publication of *Irrigated India* (London, 1893) and *Temple and Tomb in India* (Melbourne, 1893).

Meanwhile he had thrown himself heart and soul into a new movement. On 9 July 1889 Henry Parkes suggested to Duncan Gillies that the federal council—which had been created in 1885 by four colonies only—should be superseded by 'a federal parliament and executive with complete authority, upon the lines of the Dominion of Canada.' Gillies resented what seemed to him to be a slur upon the existing council, and only Deakin's tact prevented a flat refusal to consider the proposals. After much talk, however, a conference of colonial ministers met in Melbourne on 6 February 1890, Gillies and Deakin representing Victoria, and Deakin made the first of many great speeches advocating early and unfettered federation. To the convention of 1891 he went as a non-ministerial representative of his colony, took an active part in the debates, and was a member of the constitutional committee, though not of the sub-committee that actually drafted the constitution. When the convention's bill fell through, he returned to the bar, refusing all offers of office in Victoria, and confining his parliamentary work mainly to the chairmanship of the committee of accounts. In 1897 the federal movement was revived, and a convention of colonial representatives had to be popularly elected: Deakin came third on the Victorian list, and was again put on the constitutional committee; and, as before, though he took an active part in debate, his name is not connected with any important clause or section of the constitution. It was outside the convention, rather, in tactful conversations with recalcitrant members, that his work for federation was done; just as it was outside parliament, by an opportune speech during the 1898 meeting of the Australian Natives' Association, that he did most to carry federation in Victoria.

When in 1899 the constitution was adopted by majorities in five colonies, Deakin at once emerged into prominence as a statesman. The arduous campaign had won him the close friendship of Edmund Barton, and for the next four years they worked together. Their first task was to procure the acceptance of the bill by the British ministry and parliament, and in March 1900 Barton, Deakin, Kingston, Dickson, and Fysh began a series of conferences with Joseph Chamberlain, then secretary for the colonies. These are narrated under FEDERATION. The next task was to form a ministry capable of inaugurating the federal administration, and after an unpleasant interlude (caused by the governor-general's offer of the prime-ministership to Sir William Lyne, q.v.) Barton and Deakin collected round them the most prominent men of the six federating colonies. The next three years, while he was Barton's attorney-general, were probably the happiest of Deakin's life. He was a valuable adviser and a good administrator, but unhappy when he himself had to make big decisions; as long as that task was Barton's, he could go about his work unworried and in high spirits. It was during that time that he gradually formulated the principles which were to guide Australian policy at least up to 1914; the financial relations between the Commonwealth and the States, the concentration of immigration activities in federal hands, the creation of an Australian squadron, the scheme of industrial arbitration by a federal court, and many minor developments of Commonwealth activities, were devised and roughed out by him, although most of them were brought into actual being by other leaders.

In 1903 Barton, glad to leave active politics and disturbed by the resignation of Kingston and the disfavour with which his naval policy was regarded, retired to the high court bench and left to Deakin the burden of the prime-ministership. Confronted at once with the impatience of the Labour party and the sullen resistance of the official opposition, he lost ground at the elections

of December 1903, and was defeated by a combination of his opponents on a proposal to bring State business activities under the jurisdiction of the federal arbitration court (which he opposed). A few months later he aided George Reid to oust the Labour ministry that had succeeded his own, and gave Reid's ministry a passive support until May 1905. Then a speech in which he warned Reid that his support might eventually be withdrawn was taken for an immediate notice to quit, and after weeks of political turmoil he emerged again as prime minister with a small following of his own and a promise of steady support from Labour. This arrangement lasted for more than three years, during which a really protectionist tariff (with provision for preference to Britain) was established, the restrictions on alien immigration were somewhat modified, old age pensions were instituted, and a series of commercial laws (affecting copyright, trademarks, trusts, secret commissions, etc.) was passed; a beginning was also made with the military defence scheme, and negotiations were initiated with the admiralty concerning a local naval defence scheme. In 1907 Deakin visited England to take part in the colonial conference of that year, and toured the country after the conference was over in the interests of mutual fiscal preference. This exceptionally heavy strain on his physical powers brought about a collapse that was in the end to remove him altogether from public life.

Towards the end of 1908 the Labour party, which had been growing restive, withdrew its support, wrecked the ministry, and substituted one of its own under Andrew Fisher. After much hesitation Deakin decided to join the former freetraders (whose fiscal beliefs had gradually been dropped or put aside), and formed with Joseph Cook the notable 'Fusion' of 1909. In this coalition, too, Deakin's ideas were dominant, and in the year of its existence the Fusion managed to create—though in an imperfect form—the compulsory military training system, conclude with the admiralty an arrangement for the creation of the Australian squadron, and institute the high commissionership. Its existence, however, was purely a matter of parliamentary bargaining, and at the elections of 1910 it was severely defeated. The Labour ministry (Fisher's second) which then came into power set itself to carry out in full most of the measures that Deakin had for years advocated or designed, and his position as nominal leader of the opposition was much weakened by the fact that his own speeches could be quoted against him for nearly every ministerial proposal. His health, too, was failing rapidly; gradually he withdrew himself from parliament and in January 1913 left politics altogether. At the beginning of the war he served on a royal commission on foodstuffs, and at the end of 1914 was made Commonwealth commissioner to the Pan-Pacific exhibition at San Francisco; but neither rest nor travel could restore his strength, and after a long illness he died at Melbourne on 7 October 1919.

It would be difficult to exaggerate the debt which the young Commonwealth owes to Alfred Deakin; yet the bulk of Australians has probably no knowledge of it, and many prominent men (usually non-Victorians) would assert that such influence as he had was malign. The truth is that he had too telescopic a vision to see clearly what was under his feet. With his eyes fixed on the future, on the Australia that might be built up by the measures he devised, he could not see how narrow and petty were the objects of many who supported him. He had no sense of party leadership or of partisanship; he was probably the only Australian politician who ever told the electors 'Whether you vote Yes or No, provided you vote as Australians, we shall not have anything to complain of.' Thinking too far forward, he was rarely in a hurry; if opponents remained unconvinced, he would rather give them time to change their opinions than force them to yield to his majority. Consequently his political career is a succession of coalitions with men who only half understood him and had little sympathy with his aims. Possibly the best analysis of his character will be found in an anonymous article published in the *Quarterly Review* in 1911, which speaks of 'on the one hand, his personal charm, his self-forgetfulness, his high purpose, his clear distant vision; on the other, his intense dislike to compulsion, his mental remoteness, his failure to understand how arguments and acts that appeal to him will strike other people.' Apart from local politics, he was certainly the most polished orator Australia ever heard, the most widely-read and philosophic of her citizens, and the most sincere and effective advocate of her development as an important and responsible unit within the British Empire.

See Walter Murdoch's *Alfred Deakin: a Sketch.*

Deane, Henry (1847-1924), born at Clapham near London on 26 March 1847 and educated at Queen's College, Galway, and King's College, London, was employed on railway engineering works at first for the London metropolitan railways, then in Hungary, and later in the Philippine Islands. In 1880 he joined the railway service of New South Wales and rose to be engineer-in-chief; the introduction of steam tramways in Sydney and Newcastle, and the building of the Hawkesbury railway bridge (see Roads and Bridges), were undertaken during his term of office. In 1906 he retired from the New South Wales service, but in 1908 was made by the Commonwealth authorities controlling engineer of the survey for the transcontinental (Kalgoorlie to Port Augusta) railway, and in 1910 became engineer-in-chief in charge of the Commonwealth railway construction branch. For four years he organized and equipped the staff that was building the great railway, but retired in 1914, when about 200 miles had actually been constructed. He afterwards practised in Melbourne as a consulting engineer, and died there on 12 March 1924. He was an ardent botanist and a leading member of the Linnean Society of New South Wales, and was associated with J. H. Maiden (q.v.) in a good deal of work on the genus *Eucalyptus.*

Defence. See Military Defence, Naval Defence.

Demoiselles, members of the family Pomacentridae, all of small size, but so common and so brilliantly coloured that they are among the best-known fishes of the tropics. Most observers of life on coral reefs recall tiny fishes of vivid blue and orange, like living gems, that flash in and out of the maze of coral branches. These are demoiselles of the genera *Glyphisodon, Pomacentrus, Chromis,* etc., swimming either in small schools or singly. A striking black-and-white species, *Dascyllus aruanus,* is very common on the Great Barrier Reef of Queensland, where it so habitually associates with madrepores that it may be collected by the simple process of lifting the coral stock from the water with the fish

entangled among its branches. If the fish be again liberated in water where there is no coral, they become bewildered without their host, swim helplessly round one another, and can be readily recaptured by hand. Another species of *Chromis*, opalescent green in colour, also finds safety and shelter among the branches of madrepores, while various gaudily tinted species of *Amphiprion* are only found hiding among the tentacles of giant sea-anemones. These anemones are provided with myriads of stinging cells with which they capture and kill their prey, and if touched ever so lightly, cast forth innumerable poisoned darts. Yet *Amphiprion* swims freely among the tentacles without injury, even its naked eyes suffering no harm; and the anemone, ordinarily so sensitive that it retracts at the slightest touch, is unaffected by the movements of the demoiselles even when they penetrate into its open mouth.

A few representatives of the family occur in southern waters, and some, such as the White-ear (*Parma microlepis*) of Sydney fishermen and the Sailor-fish (*P. polylepis*) of Lord Howe Island, are remarkable for their extraordinary changes in colour and marking during growth.

Deniehy, DANIEL HENRY (1828-1865), born in Sydney on 16 August 1828 and educated at first at the Sydney College, was taken to England by his parents at the age of 14 and placed in charge of a tutor to be prepared for entrance into Cambridge. Wearying of study, and well supplied by his father (who had returned to Sydney) with money, young Deniehy after a few months went off to visit relatives in Ireland, met and liked the leading members of the Young Ireland party, and then made a tour of the principal picture-galleries of Europe. Returning to Sydney, he was articled to Nicol Stenhouse (q.v.) and allowed to study literature in his excellently equipped library; on 3 May 1851 he was admitted to practice as an attorney. His interests, however, were too wide to allow him much success in a profession which demands close and perpetual attention. In 1853 he delivered a course of lectures on modern literature at the Sydney school of arts; in 1854 he entered political life at a meeting of protest against Wentworth's constitutional proposals, being entrusted with a resolution condemning the proposal to institute an Australian titled nobility. In 1856, finding that his Sydney practice was not increasing, he settled in Goulburn, where he immediately made himself prominent as a politician and on 13 February 1857 was returned to the assembly for Argyle; this seat he held until 11 April 1859, and from May to November 1860 represented East Macquarie. Although his term in parliament was made notable by his co-operation with T. A. Murray and John Robertson in forcing the principle of free selection into Charles Cowper's land bill, yet he failed in politics, as in law, to make himself a permanent position. W. B. Dalley, a close friend of his youth, describes him as too uncompromising, too irritable, and too careless of the feelings of others to understand how his bitter sarcasm, indiscriminately employed, must alienate his best friends. During these years, however, he was at the height of his fame as a speaker; incapable of maintaining a continuous hold on any party or working harmoniously with any colleague, he was yet in constant request as an orator, and his brilliant invective was listened to with profound and admiring attention. But his influence on public life in the colony was exercised chiefly through the *Southern Cross*, a journal which he helped to found in 1859 and edited for the year of its existence. His contributions included both political and literary criticism, and made it the ablest Australian journal of its time. Usually dealing with matters of local and temporary interest, and couched in the half-dignified and allusive style popular among the men of his day, these articles do not produce on modern readers a tithe of the effect they had when published; but 'How I Became Attorney-General of New Barataria,' for instance, was considered at the time not only the most brilliant political satire written in Australia but one of the most brilliant in the English language. At the dissolution of 1860 he retired from politics and in 1862 settled in Melbourne as editor of the *Victorian*, a paper recently established by Charles Gavan Duffy; ill-health, and a habit of drunkenness which the sense of his own failure and the death of his eldest and best-loved son brought upon him, drove him back to Sydney, to desperate poverty, and at times to something near madness. Utterly broken down, he left Sydney for Bathurst in September 1865, and died there on 22 October.

Deniehy's reputation must always rest rather on what his contemporaries thought of him than on any lasting value in his published work. But his contemporaries were practically unanimous. Nicol Stenhouse spoke of him as 'the brightest spirit who has yet moved among us;' R. H. Horne praised his wide intellectual sympathies, his ready wit and genuine eloquence, his keen and subtle knowledge of men and things; W. B. Dalley called him 'the most brilliant of the native-born . . . an unrivalled orator by nature as well as by careful cultivation.'

Denison, SIR WILLIAM THOMAS (1804-1871), was born in London on 3 May 1804, educated privately and at Eton and in February 1819 entered the Royal Military Academy. In 1823 he passed for the royal engineers and in 1826 received his commission (lieutenant, 1826; captain, 1841; major, 1854; lieutenant-colonel, 1855; brevet-colonel, 1857; colonel, 1860; major-general, 1868; lieutenant-general, 1871). From 1827 to 1831 he was employed in Canada on the construction of the Rideau canal, and for a report on American timbers was made an associate of the Institute of Civil Engineers, and awarded the Telford medal. In February 1833 he became instructor of engineer cadets at Chatham, where he established an observatory, and in 1836 was employed as an observer at Greenwich observatory. In 1837 he was put in charge of works at Woolwich dockyard, and was employed by the admiralty until June 1846. About this time it was thought necessary to appoint an engineer officer to the governorship of Tasmania, and Sir John Burgoyne recommended Denison, who was appointed and reached Hobart on 26 January 1847. His main task was to be the reorganization of convict labour so as to provide sufficient work for all; but a large proportion of the colonists was vehemently agitating against any further importation of convicts, and six members of the council had resigned as a protest against the autocratic action of Denison's predecessor, Sir John Eardley-Wilmot (q.v.), in connection with convict expenditure. Denison's first duty was to settle this quarrel; he had power to make a selection from among the six ex-councillors and their replacers, but the matter soon became entangled in

legal technicalities, and the governor in despair dismissed the whole council until the British law officers unravelled the tangle. Thus during 1847 Tasmania was governed without a council, and only in 1848 was it announced that the Queen had reinstated the original six.

Before this puzzle was solved Denison was involved in several disputes with the supreme court. The judges had declared certain taxing acts illegal; Denison said they had not done so in time, more than 14 days having elapsed since the acts were passed. During the controversy over this point he suspended one of the judges for using his position to escape payment of a debt; this action was approved by the colonial secretary, but Denison's attempts to override the supreme court's decision about the taxing acts were disallowed. His general conduct of business, however, was commended, and he was asked to make recommendations for providing Tasmania with an elective legislature. His strong representations in favour of a two-chambered legislature, 'to check the development of the democratic spirit,' had great weight with Earl Grey when he was devising representative institutions for all the colonies in 1848-9. Hard worker as he was, and a diligent promoter of education, charity, public works, and defences, Denison was never popular in Tasmania, mainly because he disliked the proposal to abolish transportation. To reward him, therefore, for good service and at the same time to remove him from an unfriendly atmosphere, he was appointed on 20 January 1855 governor of New South Wales and (nominally) governor-general of the Australian colonies—a title which he managed to have cancelled before the end of his first year of office. In New South Wales he was far less his own master than he had been in Tasmania, but found on his hands the much more difficult task of accustoming impatient colonists to administer a 'responsible' system of government. In 1860 he complained that he had had five sets of official advisers in 3½ years, and not a single satisfactory piece of legislation from the five. His personal influence was mainly directed towards securing a sound public works system and efficient defences, and his plans for the protection of Port Jackson are commemorated in the name of an island fort in the centre of the harbour. His controversy with Charles Cowper in 1860 over the Tawell grant is narrated under Tawell, John. He was a zealous patron of music and the arts and sciences and at both Hobart and Sydney used his official residence as a meeting-place for artists and their admirers. From New South Wales (which he left on 22 January 1861) he was transferred to the governorship of Madras, where his personal ability and special skill in engineering and military affairs had fuller scope. His suggestions for reorganizing the Indian army were adopted by an army commission, though not by the British government; he encouraged irrigation works, and advocated more and cheaper railways; he strongly opposed the admission of Indians to the public service and the local councils, holding that the mass of natives did not desire to participate in the government—which is doubtless true. From 21 December 1863 to 12 January 1864 Denison acted as governor-general of India. He left Madras in March 1866, and spent the rest of his life in England, acting from 1868 onwards as chairman of a commission on river-pollution; in 1870 he published a series of reminiscences of his career under the title *Varieties of Vice-regal Life*, and died at East Sheen on 19 January 1871. (Kt. Bach., 1846; K.C.B., 1856.)

Derris, a genus of the family Leguminosae, consisting of tall woody climbers, chiefly tropical. The flowers are yellowish, white, or rarely violet, in small clusters along the flower stem; pod bordered by a narrow wing; leaves with numerous leaflets. The bark of *D. scandens*, a handsome climber, yields a coarse fibre. The pounded leaves of *D. uliginosa* are used to stupefy fish. In India its stems are used as ropes.

Devil-fishes or **Diamond-fishes,** rays of the family Mobulidae, some of which are the largest of their kind, attaining a width of over 20 feet. The disk is expanded laterally into two angular wings, producing a somewhat diamond-shaped body from which is derived the vernacular name under which these huge rays are known in Queensland. They are sometimes observed in schools of eight or ten, surrounding a shoal of small fish; they raise the ends of their pointed pectoral fins to beat the water with resounding splashes, and thereby scare their prey into a huddled mass, so that it can be readily swept into their capacious mouths by means of a pair of arm-like lobes projecting forward on each side of the head. The capture of devil-fishes with harpoons provides exciting sport and a little danger. When harpooned, a large individual will tow a small launch behind it at a great speed until it becomes tired out, but may then be hauled alongside and despatched. Sometimes, however, the fish turns upon its enemy, throws itself clear of the water, and casts its whole weight upon the boat, which is either smashed or swamped. These fish are not uncommon on the coast of Queensland, and stray individuals occasionally wander as far southward as Port Jackson.

Devil's Twine. See Cassytha.

Dewfish. See Jewfish.

Diamond-birds or **Pardalotes,** a genus (*Pardalotus*) of small perching birds, peculiar to Australia and Tasmania, generally placed in the family of flower-peckers (Dicaeidae), but sometimes regarded as constituting the separate family Pardalotidae.

Diamond-birds are brightly coloured, active little birds, generally seen in small parties searching foliage for the small insects on which they feed. Their notes are loud but rather monotonous, owing to their constant repetition and limited vocabulary. They construct beautiful domed nests of grass (or strips of bark) in a hole—either at the end of a narrow tunnel which they excavate in a bank, or in a natural hollow in a tree, the site depending on the species. It is remarkable that they can construct such elaborate nests in almost complete darkness. They lay four or five white eggs. In most species the sexes are similar.

The Spotted Diamond-bird (*P. punctatus*) is perhaps the commonest species throughout southern Australia and Tasmania. It is black and buff, with patches of red and yellow, spotted

with white and buff. Its note resembles the words 'sleep, baby.' It excavates a very long, narrow tunnel in a bank, at the end of which its

Striped Diamond-bird.

nest is placed in a chamber. The Striped Diamond-bird (*P. striatus*) is another common form, with a similar range. It has commonly been divided into three species, known as the red-tipped, orange-tipped, and yellow-tipped pardalotes—the names referring to the coloration of the tips of the small feathers on the wing at the base of the quills. The number of quill-feathers striped with white also varies. The exact status of these three forms is still not properly understood; all three have been found in south-eastern Australia, to which the orange-tipped bird appears to be restricted, the yellow-tipped extending to Tasmania and the red-tipped to Western Australia. Probably it is a case of trimorphism within a single species. In notes and habits they seem to be entirely similar, the call may be represented by the word 'wittychu,' a name by which the bird is sometimes known locally. The nest is built in a hole in a tree.

The Forty-spotted Diamond-bird (*P. quadragintus*), peculiar to Tasmania and King Island, is another of the species which nest in tree-holes. The Black-headed Pardalote (*P. melanocephalus*), of southern Queensland and northern New South Wales, excavates a tunnel in the ground. Its note resembles the words 'chip-chip,' and it is often known locally by this name. The two other species are chiefly found in the northern parts of the continent.

W.B.A.

Diamond-fishes. See DEVIL-FIHSES OR DIAMOND-FISHES.

Diamonds were first discovered in Australia by E. H. Hargraves (q.v.) near Guyong in New South Wales, late in June 1851. During the next ten years others were found in the Macquarie and several of its tributaries, but no industry was started until in 1867 a deposit of some size was discovered in the Cudgegong valley about 19 miles north-west of Mudgee. This deposit was worked for a short time, but the value of the stones recovered did not cover the heavy expenses, and a flood in 1870 destroyed practically all the plant. In 1867 diamonds were also found near Bingara, in the hills west of Inverell, and subsequent discoveries on various tributaries of the Gwydir River have produced most of the stones recorded from New South Wales. At Oakey Creek near Barraba diamonds have been found in situ in a dolerite dyke. At Mittagong diamonds were found in 1890, in clay at the bottom of a pebble drift (possibly the old channel of the Nepean River), but attempts to open a mine there were frustrated by inrushes of water. The working of the industry has been very spasmodic: during the nineties of last century, for instance, production ranged from less than 500 carats in 1892 to nearly 26,000 carats in 1899. At the present time (1925) the yield in this State is still mainly derived from the Inverell-Tingha district: it amounted in 1922 (no later figures are available) to 1000 carats valued at £1300, the total production up to that date being estimated at 201,000 carats valued at £143,000. In Victoria diamonds of small size have been found in the beds of streams running through granite country in the Beechworth district, at Kongbool in the Western district, and near Benalla. In 1912 a few small stones were found in the sluice-boxes of the Great Southern alluvial mine at Rutherglen. A few have also been found near Pilbara in Western Australia, in the Donaldson district of Tasmania, and on the Echunga goldfields in South Australia; one stone from the Echunga district was sold for £70. The yield of diamonds in the States other than New South Wales is too small to be included in the official returns. The New South Wales diamond is distinguished by its exceptional hardness.

Diamond Trevally. See PENNANT-FISHES.

Dianella, a genus of the family Liliaceae, consisting of perennial herbs—chiefly Australian, but extending to a few areas in tropical Asia, Oceania, and New Zealand. The flowers are blue, nodding, in loose sprays; fruit an ornamental blue berry; roots fibrous, often shortly creeping, the plants forming dense tufts. The fibre of *D. laevis*, which is strong and of a silky texture, was used by the aborigines for making baskets. *D. tasmanica* is mentioned in Curtis's *Botanical Magazine* as a greenhouse plant from Tasmania, whose great beauty consists of an abundance of bright blue berries; a spray is depicted in a coloured illustration. Summer visitors to Mount Kosciusko may see gorgeous masses of this lovely flower in favourable situations.

Dibbs, SIR GEORGE RICHARD (1834-1904), born in Upper Fort-street, Sydney, on 12 October 1834 and educated at St. Philip's Church of England school and the Australian College, at 22 commenced life as commission agent and wharfinger with one of his brothers, the firm being known for years as J. C. Dibbs & Co. In 1865 he settled in Valparaiso as a corn factor, and during his two years' residence there twice successfully ran the Spanish blockade with cargoes of flour and wheat. The failure of the Agra Bank drove him back to Sydney, where he resumed his old calling, extending it in 1869 to include shipowning and importing. In 1874 he entered public life as an advocate of republicanism, free-trade, and free and compulsory primary education, and on 16 December in that year was elected

to the assembly by the highly democratic constituency of West Sydney. He was not re-elected at the 1877 elections, but on 5 December 1882 was returned for St. Leonards, and on 7 January 1883 took office as treasurer in the Stuart ministry. In January 1885 he effected an improvement in public finance by withdrawing the government account from the Bank of New South Wales (which had monopolized it) and distributing it among the leading banks, which associated themselves for the purpose. During Stuart's absence in England (1884-5) Dibbs actively assisted Dalley (q.v.) in despatching the Sudan contingent to Egypt. In October 1885 Stuart resigned, and Dibbs formed his first ministry: Parkes ousted him from the St. Leonards seat, but he obtained one in the country constituency of Murrumbidgee, and for not quite three months held the premiership. After an interlude of two months during which Sir John Robertson was premier, Sir Patrick Jennings formed a ministry that lasted nearly a year (February 1886-January 1887), in which Dibbs was colonial secretary; this was a coalition ministry, and Dibbs, now more than halfway towards protection, was believed to be dragging his colleagues with him. After a stormy existence, during which customs duties were considerably increased, the Jennings ministry was displaced by Sir Henry Parkes and Dibbs went into opposition. In January 1889, owing to dissensions within the Parkes party, he formed his second ministry, and went to the country on the fiscal issue. Defeated, he gave place to Parkes, whose fifth ministry after 2½ years was ousted in October 1891 by the action of the just-formed Labour party. Dibbs thereupon returned to office at the head of an avowedly protectionist ministry, carried through a protectionist tariff, and during a visit to England in 1892 strengthened the financial position of several Australasian colonies (for he represented Victoria, South Australia, Tasmania and New Zealand as well as New South Wales) and gained the reward—he had long since abandoned republicanism—of a knighthood conferred directly by Queen Victoria. On his return he took part in a remarkable triangular parliamentary duel, three votes of censure on him being moved in a single sitting of 26 hours and 87 speeches; the first was defeated by 30 votes, the second by 62, and the third by 4. During the financial crisis of 1893, when bank after bank closed its doors, the prompt action of the Dibbs government—inspired by T. A. Dibbs (for whom see below), and R. J. Black—stemmed the panic and restored confidence by declaring notes issued by local banks to be legal tender, and in other ways giving the banks and the public breathing time. At the elections of 1894, which were fought on the fiscal question, Dibbs was severely defeated and resigned, and in the elections of the following year lost his seat and retired from politics. In 1896 he was appointed managing trustee of the government savings bank of New South Wales, and held that position until his death, which occurred on 4 August 1904.

Dibbs is chiefly remembered as the bitter opponent of Henry Parkes in his later career and as the successful champion of a protectionist policy for New South Wales. His early republicanism faded away in the course of time, as did that of many contemporaries; it was in reality the expression of a widespread opinion that in the seventies and eighties England interfered with Australia but did not help her, and died out when it became clear that the Imperial connection was essential for defence; and Dibbs, who was greatly interested in defence questions and was for 50 years a member of the volunteer forces, saw the dangers attaching to independence as soon as he began to consider world politics. His attitude towards federation was peculiar. In 1884 he moved a resolution that would have committed New South Wales to join the federal council, but was defeated by one vote. Denounced in 1880 by Henry Parkes as a pronounced opponent of the movement, he declared that he favoured it—provided that it took the shape of unification coupled with separation from the Empire. In spite of this, parliament chose him as a delegate to the preliminary conference of 1890 and to the convention of the following year. He served on the judiciary committee of the latter body, but took little part in the general proceedings, though he proposed that Sydney should be made capital of the Federation. In 1894, however, when a new federal league with proposals for the election of the next convention by the people was reviving the federal movement, Dibbs (then premier of New South Wales) put forward a scheme for the unification of New South Wales and Victoria, leaving the other colonies to come in later if they so desired—a proposal excellent in theory, but one which would have defeated its own object because no sparsely-populated colony would have allowed itself to be absorbed into one which already held 71 per cent of the people of Australia. (K.C.M.G., 1892.)

His brother, Sir Thomas Allwright Dibbs (1832-1923), born in Sydney on 31 October 1832 and educated at the Australian College, on 7 July 1847 entered the employ of the Commercial Banking Company of Sydney, in which he remained for the whole of his working life. Twenty years later he was made general manager of the bank, and for 48 years greatly influenced in that capacity the financial career of New South Wales; though less prominent in public life than his politician brother, he probably made a more permanent mark on colonial affairs. As the address presented to him on his retirement emphasized, he not only built up on sound foundations the prosperity of his bank, but 'by an enlightened policy contributed much to the rapid growth of industries and the development of the State's resources,' and was in a special manner the financial adviser of nearly every New South Wales ministry from the eighties up to 1915. In July of that year he retired from active work, but remained a director of the bank. He took a keen interest in all movements that could help soldiers, especially wounded soldiers, and gave his house and estate known as Graythwaite on the heights of North Sydney as a home for disabled men. He died on 18 March 1923. (Kt. Bach., 1917.)

Dibbs, Sir T. A. See Dibbs, G. R.

Dickinson, Sir John Nodes (1806-1882), born in the West Indian island of Grenada in 1806 and educated at Fulham and Cambridge (B.A., 1829; M.A., 1832), studied law at the Inner Temple and was called to the bar in 1840. In 1844 he was appointed a judge of the New South Wales supreme court, and for nearly 14 years worked as a colleague of Sir A. Stephen and Sir R. Therry; in 1860-1 he acted as chief justice during Sir A. Stephen's absence on leave. From May 1856 to April 1858 he was a member of the legislative council, but resigned his seat on the ground that judicial and legislative functions did not harmonize. Retiring on a pension

in February 1861, he lived quietly in England, and died while on a visit to Rome on 22 March 1882. (Kt. Bach., 1860.)

Dickson, Sir James Robert (1832-1901), born at Plymouth on 30 November 1832 and educated at the Glasgow high school, became clerk in a Glasgow bank and in 1854 migrated to Victoria and joined the Bank of Australasia. After five years in this institution and three spent with relatives in business he in 1862 moved to Brisbane to become an auctioneer, was in this business until 1899, and incidentally found opportunity to promote the Royal Bank of Queensland. In 1872 he entered politics as member for Enoggera, and pinned his faith to S. W. Griffith: consequently he was brought into the Macalister ministry of 1874-6 as minister for mines during its last days, and became colonial treasurer in the Thorn-Douglas ministries (1876-9) that succeeded it. In the first Griffith ministry (1883-8) he was again treasurer from the end of December 1883 to the middle of August 1887; but then quarrelled with his colleagues over a projected land tax, resigned, was defeated at the elections of 1888, and from 1889 to 1892 travelled in Europe. On his return to Queensland he was elected to the assembly by Bulimba, and retained the seat till the end of the century. By this time the Griffith-McIlwraith coalition had been effected, and the treasurership was in the McIlwraith section, passing from that leader himself to Nelson in 1893 and to Philp in 1898; Dickson, however, was in 1897 brought into the Nelson ministry of 1893-8, and the next year became home secretary in the Byrnes ministry, succeeding to the premiership when Byrnes died in October. A capable if verbose minister, he was not a leader; his ministry passed through many vicissitudes and collapsed in December 1899, to be followed by a seven-days' Labour ministry (the first in Australia) and by the Philp ministry of 1899-1903, in which Dickson became chief secretary. He had been for some years a strong advocate of federation, and represented his colony at the federal council meetings of 1886 and 1896; he was also a delegate from Queensland in 1900 to discuss the Commonwealth bill with the imperial government. When Edmund Barton formed the first federal ministry, Dickson was therefore the obvious Queensland candidate for inclusion, and was offered the department of defence. Sworn in on 1 January 1901, he was suddenly taken ill during the Commonwealth celebrations, and died in Sydney on the 10th. (C.M.G., 1897; K.C.M.G., 1901.)

Dilleniaceae, a family of plants consisting of 4 genera and 122 species of trees, shrubs, herbs, or climbers. The flowers are yellow or white; sepals 5, persistent; petals 5, deciduous. The family is divided into 2 groups according to the veining of the leaves; the larger group (which is entirely tropical) has feather-veined leaves; the veins of the smaller group are netted. The former group is represented in Australia by one species only, *Wormia alata,* endemic in Queensland. The most important genus is *Hibbertia* with 116 species; 114 are endemic in Australia, the remaining two being natives of Madagascar. They are mostly shrubs or undershrubs, occasionally climbers, usually much branched and with small leaves. The sections are differentiated chiefly by the arrangement of the stamens, which may be free, united in clusters on one side of the ovary only, or surrounding it, and either interspersed with infertile examples (staminodia) or with all the stamens perfect. *H. volubilis,* a herbaceous climber frequenting the coastal sand-dunes, is a useful sand-binder. The genus *Adrastaea* has one species only, *A. salicifolia,* a somewhat rare plant found sparsely on the margins of peat bogs in New South Wales and Queensland. The genus *Pachynema* has 4 endemic species. They are perennial herbs or undershrubs with small flowers, having flattened or rush-like stems and small scales representing leaves.

Dillon, Peter (1785?-1847), born in Ireland—it is not certain when—was from 1809 onwards engaged in the sandalwood trade between China and the islands (including New Zealand) of the western Pacific. In 1813 he was third officer of the *Hunter,* a vessel trading between Sydney and China via Fiji, where she was to load with sandalwood and trepang; at Fiji he was given charge of the cutter *Elizabeth,* and after a collision with the natives rescued a Prussian settler, Martin Bushart, his Fijian wife and a girl companion, and took them to the island of Tucopia, between the New Hebrides and the Santa Cruz group. It is sometimes stated that this was the first European visit to that island, but Quiros had seen it in 1606 and Barwell in 1798; Dillon mentions it as 'the island of Topie' as though it were already well enough known. His conduct in taking native women away from Fiji was sharply questioned by Macquarie, but his explanation seems to have been accepted.

From 1814 to 1823 Dillon is only heard of occasionally, but on each occasion in connection with South Seas trading. In 1824, when master of the brig *Calder,* he rediscovered an island south of the Fiji group which Cook had seen in 1774 and named Turtle Island, but which had never been put on the chart; Dillon called it Barretto Island, after a patron of his in India, and it is now known as Vatoa. In 1826 he was taking his own vessel, the *St. Patrick,* from Valparaiso to Pondicherry when it occurred to him to look in again at Tucopia. Bushart was still there, and from him Dillon obtained a silver sword-guard that had been picked up on Vanikoro: he identified it provisionally as a relic of the lost La Pérouse (q.v.) expedition, made an unsuccessful attempt to land on Vanikoro himself, and then made for Calcutta, where he gave his news to the governor-general. An expedition to search the Santa Cruz group, and if possible rescue any survivors of the French party, was at once fitted out, and on 23 January 1827 Dillon sailed from the Hooghly in the E.I.C. ship *Research.* On the way he quarrelled with his medical officer Dr. Tytler, who sued him for assault and had him imprisoned at Hobart; Arthur, however, as lieutenant-governor cancelled the imprisonment—he said Dillon justly deserved the punishment, but the relief of possible survivors must not be delayed by his wrongdoing—and on 20 May the *Research* sailed again for Tucopia, which she reached via New Zealand, Tonga, and Rotumah on 5 September. On the 8th she was at Vanikoro, and Dillon discovered that one of La Pérouse's two vessels had been wrecked on the south-western reef and the other sunk just outside it; most of the crews had re-embarked in an open boat built by themselves, and were never seen again. This information was early in 1828 confirmed by the enquiries of Dumont D'Urville in the *Astrolabe,* who saw (and had sketches made of) anchors and other objects lying on the reef where the wreck had taken place.

Dillon returned to Calcutta with his relics in

April 1828, took them to France, and presented them to Charles X, then king; his reward was the title of chevalier of the legion of honour and a pension of 4000 francs a year. In 1829 he published a *Narrative* of his voyages, mainly taken up with personal matters. His subsequent history is obscure; in 1831 he was in Paris, hoping to visit Sydney soon; in 1835 Roger Therry met him in Sydney—'a large man, weighing eighteen stone'—and found him amusing. In 1836-8 he owned the schooner *Jess* and traded in her among the Pacific islands. In 1838 he returned to Europe, settled in Ireland, and died there on 9 February 1847.

Students of history may learn to appreciate the value of second-hand evidence by looking at Therry's account of Dillon and his discoveries (*Reminiscences*, pp. 128-9). In 1½ pages of narrative there is hardly one correct statement; La Pérouse becomes a ship, Vanikoro is confused with Pitcairn Island, and every date given is wrong; yet the writer, who was a man of high character and a judge of the supreme court, had met Dillon and heard the whole story from him.

Dillwynia, a genus of the family Leguminosae, consisting of shrubs with narrow cylindrical leaves channelled above, endemic in Australia. The flowers are in numerous small clusters, yellow to orange-red. *D. ericifolia* is a heath-like bush, exceptionally variable in habit, of which the numerous varieties maintain a long succession of bloom. In *D. floribunda* the flower-clusters are crowded into a spike at the tips of the flowering stem. *D. brunioides* is a low, spreading shrub, confined to a limited area on the Blue Mountains.

Dingo or **Warrigal** (*Canis dingo*), the only indigenous land mammal of the Carnivora found in the Australian fauna. It has all the structural characters of the genus *Canis*, and is about the size of an average collie—standing about two feet high and measuring about five feet from the end of snout to tip of tail; the muzzle is pointed, the ears rather short, erect, and broad at the roots, and the tail bushy and of moderate length. The jaws are remarkable for their terrific power, which enables the animal to tear away completely the flesh gripped in its bite, and so to kill its prey by mere shock. The colour of the back varies between the limits of light reddish-brown and black; the lower surface is always lighter; the feet and tip of the tail are often white. In many parts of Australia, but especially in the districts bordering on the Gulf of Carpentaria, the aborigines catch dingo pups and train them to hunt in packs; Carstensz, the first white man to describe Australian aborigines from personal observation, records that on several occasions he found tracks of men accompanied by numerous dogs. Aboriginal women often suckle the pups, which acquire a great affection for and loyalty to their foster-mothers. In the wild state the dingo usually hunts alone or with his lifelong mate, though big game are occasionally hunted by packs. He is monogamous, and probably the most intelligent of all wild dogs, though he rarely displays the docility of domestic varieties. In unoccupied country dingoes prey on marsupials—chiefly the smaller kinds, or the young of the larger—and on such birds as they can surprise on the ground. In partly settled districts they frequently destroy sheep, calves, and poultry, and an incessant warfare is waged against them by shooting and the use of dogs, traps, and poisoned baits. West of the Darling River their depredations have sometimes been so great as to make landowners substitute cattle for sheep on their runs. In 1891 there were 15,000,000 sheep on the Western Division of New South Wales, in 1911 7,000,000, and in 1923 4,765,000; and at least half this loss is attributed by the local Pastoralists' Association to the ravages of the dingo. On the other hand, within the last five years the number of dingoes seems to be decreasing, since in 1924 only 568 were killed in the West Darling areas, against 4290 killed in 1919. South Australia has a dog-proof fence along this part of her border, and deals with the pest internally by a vermin group-fencing act.

Though extinct in the thoroughly settled areas, dingoes occur all over the Australian mainland wherever conditions are favourable. From Tasmania they are entirely absent.

Bones of the dingo have been found along with those of various extinct marsupials (such as *Diprotodon* and *Nototherium*), and, as far as present evidence goes, its arrival in Australia considerably antedated that of aboriginal man himself.

See Etheridge in the *Memoirs* of the Geological Survey of New South Wales (Ethnology No. 25, 1916); and Wood Jones in the *Transactions* of the Royal Society of South Australia, vol. xlv (1921).

Diplopoda. See MILLIPEDES.

Diprotodonts. See MARSUPIALS.

Diptera, a large order of insects whose name—two-winged—describes their essential characteristic. They are very numerous in Australia; but only a few of them—about 2000—have been described. The order is characterized by the reduction of the hind-wings to a pair of minute club-like organs, called balancers or halteres. The venation of the fore-wing is open, with scarcely any cross-veins. In the more archaic types the venation is not unlike that of caddisflies; but the first cubital vein (Cu_1) is always simple, and the full number of branches of the radial sector (Rs) is found only in a very few archaic forms. The mouth-parts are highly specialized, being adapted for piercing or sucking; the mandibles are either elongated spears, or absent; the maxillae are elongated, and in the higher types have reduced palpi; the labium has a bilobed terminal labellum, carrying more or less numerous pseudo-tracheae. The larva is very variable in form, but never possesses thoracic legs, and rarely abdominal pro-legs. In the higher forms, the larva becomes a maggot, with no visible head. The pupa is a *pupa obtecta;* but in the higher groups (Cyclorrhapha) it is developed within the dried larval skin, which forms a hard, oval puparium, and is then called a *pupa coarctata.*

The classification of this order is difficult. The usual division—which is followed here—is into two sub-orders, Orthorrhapha and Cyclorrhapha; the first sub-order has two divisions, the second three. The larva in Orthorrhapha has definite jaws set in a small head; the pupa is usually free (if it is enclosed in the larval skin, this does not assume the form of a true puparium); the head of the imago has no frontal lunule or ptilinum. In Cyclorrhapha the larva has neither definite jaws nor visible head; the pupa is enclosed in a hard, oval puparium, from which the imago escapes by making a hole at the anterior end; the imago has three-jointed an-

tennae with an arista, and in its wings neither R_{2+3} nor R_{4+5} is ever forked.

Nine species are figured on plate xi.

ORTHORRHAPHA, division Nematocera. In this division the antennae are composed of 6-40 joints, all closely similar. In the wings R_{4+5} is always a single vein (a few archaic genera excepted), and R_{2+3} either forked or single. Most species are slender and delicate. About 700 Australian species have been described, of which the dominant family Tipulidae accounts for more than a third. Flies of this family, known as crane-flies or 'Daddy-long-legs,' swarm in moist situations, their larvae living in mud, wet soil, and rotten logs. Among the large and handsomely-marked forms found in Australia species of *Plusiomyia* and *Macromastix* are notable, the latter abounding in springtime. Of the smaller species, the pretty *Gynoplistia bella* (fig. 34), is common about small streams in all parts of Australia.

The Blepharoceridae (net-veined midges) are a remarkable family of waterfall-dwelling insects, only recently discovered in Australia, though long known from New Zealand. The larvae cling to rocks, under swiftly rushing water, by means of six pairs of ventral suckers, and the pupae are also attached to rocks in similar situations. The adults sit or fly in the dense spray of the waterfalls, and are exceedingly slender and delicate insects, with long hind-legs. *Edwardsina australiensis* occurs on Mount Kosciusko, while species of *Neocurupira* and *Apistomyia* are also found on high mountain streams.

The Mycetophilidae (fungus gnats) are represented by nearly 100 species in Australia. The larva of an undetermined species is the glow-worm of mountain streams and caves; in some localities (e.g. at Bundanoon in New South Wales) the myriads of lights produced by these larvae as they hang in their webs upon the faces of moist rocks, form one of the sights of the district.

Of the Culicidae (mosquitoes, q.v.), Australia has a hundred described species, among which representatives of the maleficent genera *Anopheles* and *Aëdes* (*Stegomyia*) are included. One of the most feared of these insects, on account of its severe bite, is the Hexham Grey (*Mucidus alternans*), so named because it breeds in myriads on swampy flats at Hexham near Newcastle, N.S.W. The ordinary mosquitoes that are so annoying at night belong to several species of *Culex*, one of which (*C. fatigans*) has been introduced from ships.

Of the family Chironomidae (midges) nearly 80 species are known; about a quarter belong to the genus *Ceratopogon*, commonly called sand-flies. Although so minute, they have a very vicious bite. See BLOOD-SUCKING FLIES.

The Cecidomyidae (gall-gnats) are numerous in Australia, about 120 species having been described; most belong to the genus *Diplosis*. The spherical red galls formed on the mid-rib of eucalyptus leaves are caused by the larva of *Hormomyia omalanthi*.

Of other families, less than 20 Bibionidae are known, and a small number of Simuliidae (buffalo-gnats and Psychodidae (moth-midges). The two last-mentioned families are further discussed under BLOOD-SUCKING FLIES.

ORTHORRHAPHA, division Brachycera. In this division the antennae are nearly always composed of less than six joints, and mostly of three only (scape, pedicel, and flagellum). In the wings R_{2+3} is always a single vein, R_{4+5} forked in all but reduced forms. They are mostly stout, strongly-built flies. The number of Australian species is about 650, the dominant families being the Tabanidae (175 species), Asilidae (160) and Bombyliidae (130). The Tabanidae (March-flies) are met with everywhere; many species inflict severe bites on horses, cattle and human beings. (See BLOOD-SUCKING FLIES.) The family also contains some striking and beautiful harmless forms, especially on the highlands; note the handsome *Osca guttata* (fig. 35) and the rare *Pelecorrhynchus nigripennis* (fig. 36).

The Asilidae (robber-flies) are also met with everywhere, even in the driest parts. Australia possesses many large species, some as large as any known Diptera—e.g. the magnificent *Blepharotes coriarius* (fig. 37). Some species, e.g. *Chrysopogon crabroniformis* (fig. 38), mimic wasps. Robber-flies are useful in decreasing, by their incessant attacks, numbers of harmful insects; but some species have recently taken to attacking bees, and promise to become a serious pest to apiarists.

The Bombyliidae (bee-flies) are familiar objects in the bush, where species of the handsome genus *Comptosia*, such as *C. sylvana* (fig. 39), may be seen hovering or settling on the ground. Not unlike these are the Nemestrinidae, of which *Trichophtha'ma punctata* (fig. 40) is a well-known example.

The archaic Therevidae have their headquarters in Australia, being represented by about 60 species, none of very striking appearance. They are like small robber-flies, but without the hard, sharp beak of the latter.

The Leptidae, and the allied Stratiomyiidae (soldier-flies), are fairly well distributed in Australia, about 30 species of each being known. Of the former the biting leptids (*Spaniopsis*) are an annoyance in the bush in the autumn. Amongst soldier-flies the metallic black *Neoexaireta spiniger* is common in gardens and on window-panes, while the handsome flies of the genus *Odontomyia* may be seen on sunny days, at high altitudes, hovering motionless in the air over damp places.

Of the other families, about a dozen species of Cyrtidae (bladder-flies) are known, a few only of Apioceridae and of the large and handsome Mydaidae, and some 30 or more Empididae. Of the long-legged, metallic-green Dolichopodidae about a dozen are named; some are found resting upon citrus trees.

CYCLORRHAPHA, division Syrphoidea. This division, also called Aschiza by Brauer, includes only three families, Platypezidae, Pipunculidae, and Syrphidae. The head of the imago has neither a well-marked frontal lunule nor a ptilinum. The number of known Australian species is little over 100, of which two-thirds belong to the Syrphidae and nearly one-third to the Pipunculidae. The Syrphidae (hover-flies) are a family of handsome and beneficial insects, abundant in all parts of the world. They may be recognized by possessing a unique vein, the 'spurious vein,' developed longitudinally between Rs and M. Australia has several fine species of the widely-spread genus *Eristalis*; fig. 41 shows *E. Pulchellus*. The introduced Drone-fly (*E. tenax*) is very common in gardens. The larvae of *Syrphus* and its allies feed on aphides, and are of considerable value in checking these pests.

The large-headed parasitic flies of the Pipunculidae are not uncommon. Their larvae are para-

sitic upon various Homoptera. Perkins described 26 species of *Pipunculus* from Queensland.

CYCLORRHAPHA, division Muscoidea or Myiodaria. This division (called Schizophora by Brauer) contains a large number of families, all recognizable by the presence of the frontal lunule and ptilinum, and by a simplified venational scheme in which neither the branches of Rs nor those of M are forked. It is usually divided into the Acalyptrata—in which the squame is small, and does not fully cover the halter—and the Calyptrata, in which the squame is large, quite hiding the halter from sight.

The Acalyptrata consist of 20 or more families, very difficult to classify. Little work has been done upon the Australian species. Several handsome species of the Conopidae (wasp-flies) are to be found, but none appear to be common. The Phycodromidae (kelp-flies) are found infesting seaweed on the beaches; the Sepsidae are small black flies that breed in decaying vegetables, skins, cheese, etc.; the Ortalidae are handsome flies with metallic bodies and coloured wings, of which *Lamprogaster lacta* is one of our commonest and most beautiful species; the Trypetidae (fruit-flies), include one of our worst pests, *Chaetodacus tryoni*, the Queensland Fruit-fly (see FLIES); some striking species with stalked eyes, belonging to the genera *Achias* and *Zygotricha*, are found in Queensland.

The Calyptrata include only six families—five of which, however, are very large. The Anthomyiidae are distinguished by having the first posterior cell wide open; they include a number of species resembling the house-fly in many respects. The Sarcophagidae (scavenger-flies) are usually marked with pale longitudinal stripes; one of our commonest species is the handsome *Sarcophagus aurifrons*. To the Oestridae belong the Sheep-fly (*Oestrus ovis*), and the Bot-fly (*Gastrophilus equi*), an introduced pest. The very large family Muscidae includes the house-fly and the numerous species of blow-flies, the latter belonging to the genera *Calliphora* and *Lucilia*. These are amongst the worst of all insect pests, several species making life almost unbearable inland in the summer, while others attack sheep by blowing the wool.

The large families Tachinidae and Dexiidae are closely allied, and by some authors not separated. They contain many large and handsome species, whose larvae are for the most part parasites on caterpillars, and are therefore distinctly beneficial. One of our prettiest species, a Dexiid, is *Amenia leonina* (fig. 42). The genus *Rutilia* includes a number of very fine species, which may be seen in summer hovering high in the air, or resting upon the trunks of forest trees; of these *R. formosa* is one of the largest and commonest. The Long-legged Fly (*Myocera longipes*) is another common species, of very graceful build, often seen resting upon tree-trunks, especially in evening sunshine.

Much work remains to be done upon the Australian Muscoidea, less than 500 species having so far been described, out of probably more than 1000 existing.

CYCLORRHAPHA, division Pupipara. This division consists of parasitic and often wingless flies, living upon warm-blooded vertebrates; the larva is born just before pupation. These extraordinary insects are clearly a recent, highly-specialized offshoot of the Muscoidea. Only two families are recorded from Australia. In the Hippoboscidae (louse-flies) we have a number of species of the genus *Ortholfersia*, of which the Wallaby-fly (*O. macleayi*) is probably the best-known. The Sheep-tick (*Melophagus ovinus*) is an introduced pest.

The Nycteribiidae are wingless, spider-like insects, parasitic upon bats. A large species, *Cyclopodia pteropus*, is not uncommon on flying-foxes, while a number of smaller species have been found upon our insectivorous bats. For the economic importance of Diptera, see FLIES.

R.J.T.

Dixon, JAMES (1758-1840), born at Wexford in Ireland in 1758, educated at Salamanca and Louvain, and ordained priest in 1784, was in 1798 sentenced to death for participation in the Irish rebellion of that year. The sentence having been commuted to transportation for life, he was sent to Sydney, arriving on 16 January 1800. His excellent conduct led Governor King to regard him as worthy of emancipation, and the British government authorized this on condition he did not leave the colony; before, however, their permission was received, King on 19 April 1803 granted him a conditional emancipation in order to let him exercise his clerical functions, celebrating Sunday Mass at Sydney, Parramatta, and the Hawkesbury in rotation. This was the first recognition of the Roman Catholic Church in Australia. When the news reached Europe the Pope made Father Dixon prefect apostolic of New Holland; and King allotted to him an official salary of £60 per annum. On 1 March 1804 King reported that this measure 'had the most salutary effects' and that there was not 'the most distant cause for complaint;' and Johnston, when he rode out to suppress the Irish outbreak at Castle Hill on the 4th, took Father Dixon with him; but in the following August King withdrew the salary and cancelled the permission to officiate as priest, seemingly because he believed that the Sunday services had been turned into seditious meetings. It is probable, however, that he continued his ministrations surreptitiously until in 1808 leave was given him to return to Ireland; there he was stationed at Crossabeg in county Wexford, taking charge of the district in 1819 and dying there on 4 January 1840.

E.M.O'B.

Dobson, SIR WILLIAM LAMBERT (1833-1898), the eldest of three brothers who played a great part in the responsible government period of Tasmanian history, was the eldest son of John Dobson, a solicitor who migrated to Tasmania in 1834. W. L. Dobson was born at Gateshead in Durham on 24 April 1833, educated at the Hutchins school in Hobart, trained for the law in London, called to the bar at the Middle Temple on 6 June 1856, and admitted to the Tasmanian bar in January 1857. In 1859 he was appointed crown solicitor, and two years later entered the assembly and became attorney-general in the Weston ministry (5 February 1861), retaining the post under T. D. Chapman until 20 January 1863 and resuming it under Dry and Wilson from 24 November 1866 to 5 February 1870, when he took his seat on the supreme court bench. On 7 February 1885 he succeeded Sir F. Smith as chief justice, and held that position till his death on 17 March 1898. From 1890 he was chancellor of the university of Tasmania. (Kt. Bach., 1886; K.C.M.G., 1897.)

His younger brother HENRY (1841-1918), born at Hobart on 24 December 1841 and educated

at the Hutchins school, was called to the Tasmanian bar in 1864 and practised his profession until 1891, when he entered the assembly as member for Brighton; on 17 August 1892 he displaced the Braddon-Fysh ministry, and became premier with Adye Douglas and N. E. Lewis (q.v.) as colleagues. Ousted by Braddon on 14 April 1894, he began to interest himself in the federation movement, represented his colony on the federal council, and was elected one of its representatives to the convention of 1897-8, in which he was a member of the judiciary committee. In the campaign which followed he was a leading supporter of the bill, and in March 1901 was elected a senator. This position he held until 1910, when he was defeated. He died at Hobart on 10 October 1918. Outside politics he was a zealous and hard-working citizen, especially interested in the development of the Tasmanian tourist traffic, which, thanks to his energy, attained a great volume.

Another brother ALFRED (1848-1908), born at Hobart on 18 August 1848 and educated at the Hutchins school, was trained for the law in England, called to the bar at the Inner Temple on 25 January 1875, and admitted to the Tasmanian bar on 10 September in the same year. He entered politics almost immediately, being elected for Glenorchy to the assembly in June 1877, and on 13 August became attorney-general under Philip Fysh. In 1882-4 he was leader of the opposition; in July 1885 he was elected speaker of the house, but on 29 May 1887 resigned to take the non-political post of solicitor-general. In April 1901 he was made agent-general for the State in London. He was accidentally drowned in the English Channel on 5 December 1908. (C.M.G., 1904.)

Dock. See NOXIOUS PLANTS.

Docks. See HARBOURS and MORT'S DOCK.

Dodder. See CONVOLVULACEAE.

Dodds, SIR JOHN STOKELL (1848-1914), was born at Durham in England in 1848 and brought to Tasmania as a boy. His father died when he was 16, and thenceforward he supported his mother in addition to educating himself. According to tradition, he became an office boy when so small that his head could hardly be seen over the counter. He read for the law, and was called to the Tasmanian bar in 1872; he also found time for a very successful career in rowing, a sport in which he retained a life-long interest. Entering politics in 1878 as member for East Hobart, he took office in December as attorney-general in the Crowther ministry, and retained that office for two years in the Giblin ministry that followed it; on 1 December 1881 he exchanged offices with Giblin, and became treasurer; when Giblin went to the supreme court in 1884, he reverted to his old position under Adye Douglas, and retained it under J. W. Agnew until 15 February 1887, when on Giblin's death he took the vacant judgeship. He was thus in office continuously for more than eight years under four premiers. He represented Tasmania on the federal council in 1886, and at the colonial conference of 1887.

In 1894 he acted as chief justice during the absence of Sir W. L. Dobson, and succeeded to that post on Dobson's death in 1898, becoming also lieutenant-governor in 1903. Apart from politics and the law, he interested himself in literature, education, and sport, and was from 1907 to 1914 chancellor of the university of Tasmania. He died on 23 June 1914. (C.M.G., 1889; K.C.M.G., 1901.)

Dodonaea, a genus of the family Sapindaceae, consisting of shrubs (often tall) and, rarely, trees; 50 species are endemic in Australia. The flowers are unisexual, the sexes often on distinct plants; fruit usually a membranous capsule; leaves simple or divided into leaflets. These plants are generally known as 'hop-bushes,' since the inflated fruits, both in taste and in appearance, resemble the common hop. Many species are ornamental shrubs, worthy of cultivation, and are easily propagated from seeds. The leaves of several species growing in arid districts are eaten by stock in times of drought. *D. viscosa* extends to India, where its timber is used for turnery, inlaying, etc. The wood is dense and of a flinty nature, and will often turn or notch the edges of a well-tempered axe.

Dog-fishes, small sharks of the family Squalidae which have a stout spine before each dorsal fin; they are often called 'piked dog-fish' to distinguish them from the species of another family (Scylliorhinidae) which are known to English fishermen as 'hounds.' Piked dog-fish or skittle-dogs are abundant in all cool seas, and as many as 20,000 have occasionally been taken in a single haul of a net. In some countries they are largely sought by fishermen for the oil contained in their livers, while their flesh is of such good quality that a considerable quantity is imported into Australia and sold under various fictitious names, e.g. 'smoked haddock.' Several species are plentiful in Australian waters, and are taken by trawlers. They attain a length of nearly three feet; but a species occurring in the Philippine Islands bears the distinction of being the smallest shark known, adults being only six inches long.

Allied to the dog-fishes are a number of little-known genera and species that occur in deeper waters. The extraordinary Prickle Shark (*Oxynotus*) is entirely covered with short spines; its curious angular body is compressed, and sharply demarcated from the perfectly flat belly. Others, of the genera *Spinax* and *Etmopterus*, which are restricted to deep waters where no daylight penetrates, are black in colour and have luminous organs on the lower surface.

A. R. McC.

Dogwood, vernacular name of *Myoporum platycarpum* (see MYOPORUM); but the Tasmanian dogwood is a *Bedfordia*.

Dolichos, a genus of the family Leguminosae, consisting of twining or trailing herbs, rarely erect; largely South African, with a few tropical and South American species. The only species indigenous to Australia is *D. biflorus*, the 'horse gram' or 'kulthi' of India. The beans are usually fed to horses, but the whole plant is useful as fodder. The poorer class of natives in the Punjab use the beans as an article of diet. Several exotic species are grown as ornamental vines.

Dollar-bird, the only representative in Australia of the family of birds known as rollers (Coraciidae), bright-plumaged birds found throughout the warmer parts of the eastern hemisphere. The Dollar-bird (*Eurystomus orientalis*) has greenish-blue plumage with a large round white patch in the centre of each wing, very conspicuous when it is flying. These patches

are said to be the origin of its name, as they look like silver coins. The beak is very wide, and bright red in colour.

Dollar-bird.

The dollar-bird occurs throughout northern and eastern Australia during the summer, retreating northwards to the Malay Archipelago for the winter. It is very noisy, with a peculiar, chattering note; its flight is remarkable, as it rarely flies straight for any distance, but tumbles and twists in the air. This peculiarity, which it shares with the rest of the family, accounts for the name 'rollers.' The white eggs are laid in a hole in a tree, generally near the extremity of a dead branch, and the bird is clever enough to mislead searchers for its nest by flying into other holes. W.B.A.

Dolphins, vernacular name of the family Delphinidae and especially of the genus *Delphinus*, the typical species of which—*D. delphis*, the Common Dolphin—ranges over all seas except the Arctic and Antarctic areas. In Australia, however, where the Porpoise (*Phocaena communis*) of European seas is not known, *D. delphis* is usually but wrongly called 'porpoise;' porpoises, however, have a rounded muzzle, while dolphins have a sharply-defined, narrow beak. Skeletons of the common dolphin are to be seen in the Australian (Sydney), National (Melbourne), and Queensland (Brisbane) museums. Besides the common dolphin two or three other species of dolphin occur in Australian seas.

The Southern Bottle-nosed Dolphin or Cowfish (*Tursiops catalania* or *truncatus*), which inhabits Australasian seas, is distinguished from the true dolphins (*Delphinus*) by its shorter and more tapering beak, and the smaller number and larger size of the teeth. A skeleton and a coloured cast of this dolphin are in the Australian Museum, and a skull in the Queensland Museum.

Long-beaked dolphins of the genus *Sotalia*—which are estuarine, and ascend rivers in other parts of the world (e.g. Brazil and China)—are known to occur on the Australian coast; but nothing seems to be known of their mode of life. A skeleton of *S. gadamu* and a skull and mounted specimen of *S. lentiginosa* are in the Queensland Museum. W.A.H.

Domatia are peculiar structures found on the leaves of certain plants, of which *Pennantia Cunninghamii* (see OLACINACEAE) is a good example. On the under-side of the leaf they form small round openings, with a thickening round the orifices, occurring at the axils of the primary and secondary veins and again in the secondary and tertiary axils. These open into an almost spherical cavity, which on the upper surface of the leaf, shows as a little hump. Lundstrom's theory of their structure is that they are 'hereditary galls' caused in the remote past by minute acari, but now produced without these mites—a good instance, if true, of the transmission of acquired characters. Continued observation of these structures does not, however, favour this theory; but no other satisfactory explanation has been given. It is remarkable that the majority of domatia-bearing plants grow in the southern hemisphere, whereas in Australia none occur on plants in sandstone country.

Donaldson, SIR STUART ALEXANDER (1812-1867), son of a London merchant with Australian trade connections, was born in London on 10 December 1812, educated privately, and in 1832 sent by his father to the silver-mines of Guanajuato in Mexico for business training. Returning to England in 1834, he migrated to Sydney to enter the employ of Dawes, Gore & Co., rising later to be head of the firm and transforming it into Donaldson & Co. In 1848 he entered the legislative council as member for Durham, retaining the seat until February 1853; he was a marked man from the start, and in 1849 was an unsuccessful candidate for the speakership. Associating himself with Wentworth, Martin and Lowe, he took a prominent part in the long campaign for responsible government; he was also an active supporter of Caroline Chisholm's (q.v.) colonization scheme, and an ardent advocate of steam communication with Britain. In 1853 he left the council to visit England, but rejoined it two years later as member for Sydney Hamlets, and was for a time vice-president. When responsible government was given the colony in 1856, Donaldson and Charles Cowper (q.v.) were the two most prominent men in local politics; neither would serve under the other, and Denison asked Donaldson to form the first ministry. Parties being still inchoate and party discipline non-existent, the ministry lasted less than three months, and was succeeded by a Cowper ministry that lasted barely five weeks; then Donaldson took office again as treasurer in a ministry headed by Henry Watson Parker (q.v.) which stayed in for 11 months; on leaving office in 1857 he was made commissioner for railways. During these years he was member of the new assembly for Sydney Hamlets (March-October 1856) and the south riding of Cumberland (November 1856 to April 1859). By this time he had wearied of colonial life, and at the elections of 1859 abandoned politics and returned to England. There he re-entered business (from which he had retired when made premier), made several unsuccessful attempts to gain a footing in British politics, and died at Carleton Hall in Cumberland on 11 January 1867.

His public services were remarkably varied. He was from the first a believer in establishing local industries, and in the late forties had a

cloth factory at Stockton near Newcastle, N.S.W. He helped to found the university of Sydney—although he opposed Wentworth's bill of 1849 on points of detail—and was a member of its senate from 1850 to 1861. As first premier he had to formulate a scheme of departmental administration, and devised one with four main departments—each represented in parliament by a minister—a chief (or 'colonial') secretary's, an attorney-general's, a treasurer's, and one of lands and works; he also abolished the custom by which the auditor-general had been a political officer. His tenure of office under H. W. Parker was responsible for several valuable acts, but particularly for his insistence on sound finance: confronted with the British government's determination to make a separate colony in the north, he led the assembly in protesting both against the suggested revival of transportation to Moreton Bay and the districts north of it and against including New England and the Clarence River valley in the new colony. Among the minor events of his life his duel with Sir T. L. Mitchell (who had, he considered, offended his honour by a speech) is best remembered; but it was taken seriously by no one except (possibly) the duellists themselves, and they were neither injured nor reconciled. This was the last duel fought in Australia. (Kt. Bach., 1860.)—His younger brother, JOHN WILLIAM DONALDSON (1811-1861) was the author of the *New Cratylus, Varronianus* and other famous works of classical scholarship.

Stuart's son, ST. CLAIR GEORGE ALFRED DONALDSON, born in London on 11 February 1863 and educated at Eton and Trinity College, Cambridge, was ordained in 1888, made head of the Eton mission at Hackney Wick in 1891, was rector of Hornsey in 1901-4, and was installed Anglican bishop of Brisbane on 21 December 1904. His see was raised to an archbishopric in the following year, when the dioceses of Brisbane, Rockhampton, North Queensland, Carpentaria, and New Guinea were formed into a province with him as metropolitan. His energy so hurried forward the building of St. John's cathedral at Brisbane—the foundation-stone of which had been laid in his predecessor's time—that an important part of it was in use before he left the diocese. His chief work, however, was educational: he founded St. Francis College at Nundah for training young ministers, St. John's College within the university of Queensland, and seven important secondary schools attached to the Church of England in southern Queensland, and was active in procuring the admission of the clergy of all denominations to give religious teaching in state schools. In 1921 he resigned the archbishopric, and returned to England to become bishop of Salisbury.

Donohoe, ANDREW (1842-1897), born in Sydney in 1842, obtained a certain amount of theatrical experience from amateur performances and work with travelling companies in Australia—his first public appearance was made in a hall attached to the Red Cow inn at Parramatta. He was unknown to fame until, after much provincial work in England, he appeared with Dion Boucicault in 1870 under the *nom de théâtre* of Shiel Barry. Several years of stock work followed: but in February 1878 he appeared as Gaspard in *Les Cloches de Corneville*, a performance which was largely responsible for the play's three-year run and frequent revivals, and which was described by a competent critic as belonging 'to the very highest order of eccentric comedy.' Securing the rights of the play, he toured England and the United States with it; occasionally he appeared in other parts, but they seem to have been of the same type, written up to his reputation as Gaspard. He died on 13 March 1897.

Dorcas Kangaroo, a genus (*Dorcopsis*) of the Macropodidae (see KANGAROOS) supposed to connect the tree kangaroos (q.v.) with the more normal members of the group. The three species are all confined to Papua; in them the disproportion between the fore- and hind-limbs is less strongly marked than in the ordinary kangaroos, though more strongly than in the tree kangaroos. The name *Dorcopsis* (from *dorcas*, an antelope) is meant to signalize this feature, and the general proportions of head and body. One of the species, the Brown Dorcopsis (*D. mulleri*), is an inhabitant of north-western Papua and some of the adjacent islands. Another, the Grey Dorcopsis (*D. luctuosa*), is found in the east and south-east, and the third, Macleay's Dorcopsis (*D. macleayi*), has been found on the south coast. On Mysol Island is found a small distinct insular species (*D. mysoliae*) allied to *D. mulleri*. See MARSUPIALS. W.A.H.

Dories, fishes of the family Zeidae. The well-known John Dory (*Zeus faber*) of European seas also occurs in Australian waters, and is not infrequently captured by trawlers. It is of rather hideous appearance, having a greatly compressed body with long trailing fins, huge saucer-like eyes, and a remarkably extensible and capacious mouth. On each side of the body is a circular spot, which tradition says was left by the thumb and finger of St. Peter upon

John Dory.

the ancestors of this species when he captured specimens to obtain tribute money. From the times of the Romans onward, the John Dory has been ranked as one of the finest of table-fishes, and, since it sometimes reaches a length of two feet, and is firm and fleshy, it commands a ready sale. Another rarer but equally palatable species is the Mirror Dory (*Zenopsis nebulosus*) of deep water, whose smooth, scaleless, and circular body is brilliantly silvered like a looking-glass. The Silver Dory (*Cyttus australis*) is another deep-water representative, as is the Big-eyed Dory (*Cyttosoma boöps*), found at depths of 300 fathoms in the Great Australian Bight; in this species the eyes reach their maximum development, and occupy more than half the entire bulk of the head. A.R.McC.

Dormouse Opossum, a genus (*Dromicia*) of pigmy Australian phalangers (see OPOSSUMS). In the Pigmy Dormouse Opossum (*D. nana*) the head and body together are about four inches long, the tail a little more than four inches. The fur is soft and thick, of a uniform dull fawn colour above, lighter below. The ears are relatively large and thin. The tail is slender and cylindrical, furry at the base, scaly in the rest of its extent. *D. nana* is common in Tasmania, and has quite recently, after careful search, been found to be numerous in some parts of New South Wales and Victoria. It forms nests of leaves in hollow limbs of eucalyptus trees.

Still smaller is the Lesser Dormouse Opossum (*D. lepida*), which is confined to Tasmania. The Long-tailed Dormouse Opossum (*D. caudata*), whose tail is nearly half as long again as its head and body together, inhabits north-western Papua, and the Western Dormouse Opossum (*D. concinna*) occurs in South and Western Australia. The closely allied genus *Endromicia* is represented by *E. macrura*, found on the Atherton-Herberton tableland in northern Queensland; it resembles *D. caudata*, but the body is longer and the tail shorter. Its coloration is light chocolate-brown above, grayish white below.

The vernacular name of the genus *Dromicia* refers to its habit of curling up like a dormouse when it hibernates. See MARSUPIALS.

Douglas, JOHN (1828-1904), born in London on 6 March 1828 and educated at Rugby school and the university of Durham, migrated to New South Wales in 1851 and was appointed a goldfields commissioner. Dropping this to take up squatting—in which he had little success—he entered New South Wales politics in 1859, represented Darling Downs for five months (until Queensland became a separate colony) and Camden for seven; then, making his home in Queensland, he left the New South Wales assembly and was elected to the Queensland house on 21 July 1863 for Port Curtis. Being an able and well-educated man and a good speaker, he soon became a recognized candidate for office. He served in the Macalister ministries of 1866-7 as postmaster-general, colonial treasurer and secretary for public works, and in the Lilley ministry of 1868-70 as postmaster-general, but resigned in November 1869 to become agent-general for the colony. In 1871 he returned to Queensland, in 1875 was elected for Maryborough, and was secretary for lands in the Thorn ministry of 1876-7. Out of the remnants of the Thorn ministry (see THORN, GEORGE) he formed a ministry of his own, with S. W. Griffith as his attorney-general and chief colleague, which lasted from 8 March 1877 to 21 January 1879. He was then defeated by Thomas McIlwraith, but continued to take an active interest in politics, and on 4 February 1881 publicly advocated the construction of railways by means of land grants—some enterprising company being formed to build the line, taking its pay in grants of land along the route, and handing over the completed line to the government to work. This policy was afterwards taken up by McIlwraith. In 1885 Douglas was made government resident at Thursday Island, and held the post till his death on 23 July 1904. From December 1885, when Sir Peter Scratchley died, to September 1888, when British New Guinea was proclaimed a British possession, he was also special commissioner for that protectorate.

Douglas, SIR JOHN ADYE (1815-1906), born near Norwich in England on 30 May 1815, and at first intended for the navy, was diverted to the law, became a solicitor in 1838, and next year migrated to Hobart and was admitted to the local bar. After an interlude of squatting in Victoria, he settled at Launceston in 1842 and there became a leading lawyer. In the early fifties he was active among the anti-transportationists (see TRANSPORTATION), and in 1855 entered the legislative council as member for Launceston. His activities as a citizen were manifold; he vigorously advocated the building of railways, was a member of the council of the university of Tasmania, and consistently urged the closer union of the Australian colonies. He represented his colony (*a*) in 1863 at a conference on intercolonial tariffs, (*b*) in 1887 at the colonial conference in London, (*c*) in 1891 at the federal convention in Sydney. His career in local politics was uneventful. In the assembly he represented successively Westbury, Norfolk Plains, and Fingal; became premier in 1884; resigned in 1886 to become the first agent-general of the colony; returned to Tasmania at the end of the following year, and re-entered the council as member for Launceston in 1890; was chief secretary in the Dobson ministry from 1892-4, and then became president of the council. In 1904 he retired from public life, and died at Hobart on 10 April 1906. (Kt. Bach., 1902.)

Dove. See PIGEONS.

Dowling, SIR JAMES (1787-1844), born in London on 25 November 1787 and educated at St. Paul's School, while studying for the bar earned his living as a reporter of parliamentary debates, was called to the bar at the Middle Temple on 5 May 1815, and for many years practised on the home circuit and at the Middlesex sessions, being also joint-editor of Dowling's and Ryland's *King's Bench Reports*, 1822-31, and of *Reports of Cases Relating to the Duty and Office of Magistrates*, 1823-31. Early in June 1827 he approached Lord Goderich with an offer of his services whenever a colonial judgeship should be vacant, obtained the backing of Henry (afterwards Lord) Brougham, declined the chief justiceship of Dominica and the chief justiceship of Sierra Leone on account of the climate, and on 6 August of that year was made a puisne judge of the New South Wales supreme court, entering on his duties on 3 March 1828. Eight years later he became acting chief justice during the absence of Sir F. Forbes, and on 30 August 1837 was confirmed in that office; he thus became an ex-officio member of the legislative council, but took no active part in the angry debates of the time. By 1844 he was worn out; 'during the whole period of his career' says Sir R. Therry, 'he was daily engaged in some one or other of the multifarious duties of the supreme court . . . In New South Wales a judge has no respite from work, no Long Vacation; the court may literally be said to be sitting the whole year round.' He obtained leave of absence, and was on the point of sailing for England when he died on 27 September 1844.

An excellent case-lawyer, a fluent speaker, and a kindly and considerate man, he enjoyed great and constant popularity in his lifetime, and

died a victim to scrupulous anxiety and excessive toil. Several of the Sydney streets record his memory. Receiving, as was usual in those days, a grant of land within the precincts of Sydney, he chose a block on the far side of what was afterwards known as Woolloomooloo; when streets were made through this land, he gave them the names Victoria (his Queen), Brougham (his patron), Forbes (his colleague) and Dowling. (Kt. Bach., 1838.)

His son, JAMES SHEEN DOWLING (1819-1902), born in London on 2 December 1819 and educated under Dr. Lang and W. T. Cape and at the Sydney College, was sent to England in 1836 to study law, graduated LL.B. at King's College, London, in 1841, and was called to the bar at the Middle Temple in 1843. Hearing of his father's death, he returned to Sydney in 1845, was admitted to the New South Wales bar on 20 October, and in 1846 made judge advocate for the new colony of North Australia (see GLADSTONE COLONY). This appointment, however, was extremely brief: he left Sydney with Colonel Barney on 8 January 1847, and was back again by 4 May, Earl Grey having suddenly countermanded the orders of W. E. Gladstone for the foundation of the colony. Resuming his practice in Sydney, he became successively police magistrate (1851), crown prosecutor for the colony (1857), and district court judge (1858). In August 1889 he retired on a pension, and died on 4 May 1902.

Downer, SIR JOHN WILLIAM (1844-1915), was born at Adelaide on 5 July 1844, educated at St. Peter's College, trained for the law, admitted to the local bar in 1867, and made a Q.C. in 1878. In that year he was elected to the legislative assembly from Barossa, which constituency he represented continuously until 1901. From 1881 to 1884 he was attorney-general in the Bray ministry and responsible for important legal reforms; from 1885 to 1887, and again in 1892-3, he was premier. Interesting himself in the movement towards federation, he represented his colony at the Sydney convention of 1883, the colonial conference in London in 1887, and the federal conventions of 1891 and 1897-8; he was also a South Australian member of the federal council of 1889. He was elected to the first senate of the Commonwealth (1901-3), but at the end of the term returned to State politics and in 1905 entered the State legislative council; of this body he was a member till his death at Adelaide on 2 August 1915. (K.C.M.G., 1887.)

Dracophyllum, a genus of the family Epacridaceae, consisting of four species (shrubs or small trees) distributed over Australia, New Zealand, and the Antarctic islands. The flowers (white, pink, or purplish) are in spikes; corolla-tube cylindrical to bell-shaped with 5 spreading lobes; stamens enclosed in the tube. The closely packed leaves, whose bases sheath the stems as in *Dracaena* (from which the generic name is derived), give a monocotyledonous aspect to the plant. *D. secundum* grows in the crevices of dripping rocks. Its pendulous branches, tipped with spikes of creamy white or pink flowers, are very attractive.

Dragonflies, insects belonging to the order Odonata, of which nearly 200 species are known in Australia. Though frequently miscalled 'horse-stingers,' they are quite harmless and even beneficial, as they destroy mosquitoes and other small insect pests.

The order is one of the oldest and most isolated of winged insects. The imagines are recognizable by their extraordinary facies, resembling miniature aeroplanes; some of the more important ordinal characters are the minute antennae, huge eyes, tiny neck pivoting the head, reduced prothorax, and immensely strong synthorax placed obliquely to the rest of the body —so that the legs are brought forward, close up to the mouth, while the wings are placed far backward above the base of the abdomen. The abdomen is long and slender, with the unique copulatory apparatus of the male on its second segment; the scheme of venation also is unique and complicated, with its triangle or quadrilateral, nodus and pterostigma. The larvae are aquatic, and are characterized by the possession of a unique prehensile mask formed from the lower lip. There are two well-marked sub-orders.

In the sub-order Anisoptera the hind-wings are somewhat shorter and broader than the fore-wings; an oblique vein and a true triangle are always present. When at rest the wings are held extended. The larva breathes by means of very highly-developed rectal gills.

The large family Aeschnidae, which contains some of the most archaic of all dragonflies, is well represented in Australia. Huge species of *Petalura* occur on mountain swamps in eastern Australia; *P. ingentissima*, which expands 6½ inches, is one of the largest dragonflies known. The very beautiful Petaliinae are represented by two genera, their nearest allies being found in Chile; these dragonflies—of which *Austropetalis patricia* (plate xix, fig. 17), from the Blue Mountains in New South Wales, is the best-known—are marked with brown or ruby spots along the wing-border; their larvae live on the faces of waterfalls, clinging to moss, debris, etc. The Gomphinae are well represented by numerous species of *Austrogomphus* and *Hemigomphus;* the beautiful, large, spotted Aeschninae, whose headquarters are the sub-alpine highlands, by many magnificent forms, of which the grand *Austrophlebia costalis* is probably one of the swiftest insects in the world, its speed being estimated at nearly 60 miles an hour. The dominant genus in this sub-family is *Austroaeschna,* with more than a dozen species.

The Libellulidae are especially well represented by their older sub-family Corduliinae, which has its headquarters here. The dominant genera are *Synthemis* and *Hemicordulia,* the former containing graceful, slow-flying insects with bodies beautifully marked with creamy or yellow spots, the latter swift-flying green and orange species with brilliant green eyes. The small orange-and-black species of the genus *Cordulephya* sit with their wings closed, like damsel-flies. Numerous genera of the sub-family Libellulinae are also to be found, especially in Queensland, where a large number of offshoots from the Oriental fauna have taken possession of the coast-line. The most striking of these are the brilliant red-bodied species of *Lathrecista, Orthetrum, Rhodothemis,* and *Diplacodes,* and the glorious butterfly-like *Rhyothemis,* which floats airily about displaying the gorgeous colours of its wings.

The sub-order Zygoptera comprises the smaller species known as damsel-flies, distinguished by their slender build, the equal size of the fore- and hind-wings (which are nearly always held folded over the body in repose), the absence of a true triangle (a simpler formation of a narrow quad-

rilateral cell being present), and the absence of the oblique vein. The larvae possess three elongated caudal gills; but respiration is shared between these and the rectum. The beautiful Calopterygidae, with their gorgeously coloured wings, are mostly a tropical group, the only Australian genus being *Diphlebia*, containing some lovely blue-bodied species found resting on rocks, twigs, etc., with outspread wings. The most striking of these is the black-winged *D. euphoeoïdes*, from northern Queensland (plate xix, fig. 18).

As regards the family Lestidae, Australia is the home of the archaic genus *Synlestes*, of which the best-known species is *S. weyersi*, with a very long and slender body, brilliant metallic-green in colour. The bronze and blue species of *Austrolestes* are abundant in most localities.

The dominant family Agrionidae contains many interesting forms. Chief among these is *Argiolestes*, a genus which rests with outspread wings and contains some beautiful species; though *A. icteromelas*, by far the commonest, is a very dull creature. The large *Podopteryx roseonotata* (rich black with pink spots on the thorax) is a rare insect found only in the scrubs of northern Queensland, where it is called 'wongera-wongera' by the aborigines. A number of species of the highly reduced Protoneurinae, the slenderest of all known insects, are found in eastern Australia, the best-known being the lovely orange-and-black *Nososcticta so'ida* (plate xix, fig. 19). In the sub-family Agrioninae are many small species, of which we can only mention the red-and-bronze *Xanthagrion erythroneurum*, common on all inland waters, and the equally common, but smaller and more brilliant, *Ischnura aurora*, one of the loveliest little creatures imaginable. Equally interesting is the metallic green *Hemiphlebia mirabilis* which indulges in a remarkable courtship before pairing, the male and female waving signals to one another from the reeds, and then flying out and indulging in a miniature *pas de deux*.

See Tillyard's *Biology of Dragonflies* (1917), and his papers in the *Proceedings* of the Linnean Society of New South Wales, 1905-18, and in the *Journal* of the Linnean Society of London, 1916.

R.J.T.

Drake, James George, born in London on 26 April 1850 and educated at King's College school, in 1874 migrated to Queensland and took up journalism, eventually joining the Hansard staff in Brisbane and studying law in his spare time. In 1882 he was admitted to the local bar; in 1888 he was sent to the assembly by the Enoggera electorate, and retained the seat until 1899, when he was nominated to the council. Entering federal politics in 1901, he was elected senator from Queensland, but retired altogether in 1906 and resumed the practice of his profession. On 7 December 1899 he joined the Philp ministry as postmaster-general and secretary for public instruction, and on 1 February 1901 left this position to become postmaster-general in the first (Barton) federal ministry. In the 'general post' which followed Kingston's resignation in August 1903 Drake became minister for defence for six weeks, in the succeeding (Deakin) ministry was attorney-general, and in the Reid-McLean ministry vice-president of the council. His name is not connected with any special legislation. On 13 January 1910 he was appointed crown prosecutor in the district courts of Queensland, and retired on 30 December 1920.

Drama. The first play connected with Australia was performed neither in Australia nor in London, but in Paris, where on 24 November 1792 'Les Emigrés aux Terres Australes' was produced at the Théatre des Amis de la Patrie. Suggested by the travels of La Pérouse (q.v.), who had been last heard of at Botany Bay, it depicted the adventures of exiled French aristocrats—a prince, a marquise, a baron. a judge, an abbé, and a banker—when confronted with the 'noble' savages of the Australian wilds, and held them all up to scorn as compared with a common labourer; it might be described as the 'Admirable Crichton' of the French revolution. Its supposedly Australian background bears, of course, no relation to fact.

Theatres and Productions.—The first dramatic performance in Australia was given on 4 June 1789 by a party of convicts, who staged 'The Recruiting Officer' in honour of the King's birthday. Their example was followed by soldiers and convicts both in Sydney and on Norfolk Island, and on 16 January 1796 the first Sydney theatre (erected by Robert Sidaway, an emancipist) was opened under the management of J. Sparrow with Young's tragedy 'The Revenge,' followed by an afterpiece 'The Hotel.' (The alleged 'Barrington' prologue, which is dealt with under that name, was not spoken on this occasion, being a mere *jeu d'esprit* written in England some years later.) The style and capacity of the theatre may be gauged by the price-list—boxes, 5s.; front boxes, 4s.; pit, 2s. 6d.; gallery, 1s., payment being made in money, flour, meat, or spirits. To procure these commodities and so obtain admission to the performances many petty thefts were committed, and Governor Hunter in 1798 closed the theatre and ordered the building to be pulled down. A second, established in 1800, had but a brief existence. For the next 30 years the settlement was dependent for its theatrical amusements on amateur performances, given sometimes by convicts, sometimes by regiments of the garrison, occasionally by visiting men-of-war; thus on 8 January 1830 the officers of H.M.Ss. *Crocodile* and *Zebra* performed 'Agnes, or the Bleeding Nun' and 'The Miller and his Men' in a marquee at Fort Macquarie. Sydney's first regular playhouse dates from 1832. In December of that year Barnet Levey, having obtained from Governor Bourke a licence 'for the production of pieces sanctioned by the Lord Chamberlain,' adapted for play-production a saloon at his George-street hotel, and performances were given there until the Theatre Royal, which was being erected at the rear of the hotel, was opened on 5 October 1833 with 'The Miller and his Men' and 'The Irishman.' This date marks the beginning of the continuous history of the Australian stage.

The company at the Royal during its early years was quite reputable. It included Conrad Knowles, a scholarly Shakespearian who later took over the management of the Melbourne Royal Theatre; Joseph Simmons, who after a brief managerial experience at the Royal became lessee of the Victoria Theatre, opened in 1838; Spencer, for some years regarded as the only tragedian in the country; Mrs. Taylor, the most gifted and versatile member of the company; and Eliza Winstanley (see O'Flaherty, Eliza), a native of Sydney, who afterwards joined Charles Kean's company at the Princess Theatre in London. Mrs. Chester of Drury Lane visited the Royal for a season in 1836. This house was closed on 22 March 1838; four days later the Victoria Theatre, a larger building erected in Pitt-street between

King- and Market-streets, was opened by Joseph Wyatt, who took over most of the company from the Royal, and in addition engaged some artists from Hobart. This theatre, long and affectionately known as 'the Old Vic.,' stood on the site since occupied by McCathie's drapery shop; just across Pitt-street was the Clown inn, kept for a time by George Coppin. The Victoria opened with 'Othello,' Arabin from Hobart playing the Moor, Spencer Iago, and Eliza Winstanley Desdemona. The usual round of tragedy, three-act drama, and burlesque was produced until March 1839, when a small French company gave a season of vaudeville, opera-bouffe, and French drama. In 1841 Dalle Casse, an acrobat who appeared for a short time at the Victoria, ran a circus under canvas in Hunter-street: this venture proving a failure, he converted it in 1842 into the Olympic Theatre, engaging as its manager Knowles, from the rival 'Old Vic.' Luckily for the older theatre the arrival of Francis Nesbitt McCron (who dropped his surname for theatrical purposes), and his success in a series of tragic and Shakespearian characters, warded off disaster. For Nesbitt was written the first play by a colonial author—'The Hibernian Father,' by Geoghegan, produced on 23 May 1844. The first star actor from the old country to appear on the boards of the 'Old Vic.' was, by his own account, George Selth Coppin (q.v.). In 1845 the theatre was occupied by a company that played grand opera three times a week, tragedy twice, and burlesque once; its prima donna was Theodosia Yates (playing as Yates Stirling), a descendant of the great Mrs. Yates of Garrick's days and the mother of Nellie Stewart (q.v.).

The only other town which at this time had a comparatively long theatrical tradition was Hobart. Before the opening of 'The Theatre'—later known as the Theatre Royal—in 1834 by a Mr. Cameron (who at the same time opened a makeshift theatre at Launceston), a Mrs. Clarke ran a company that played in a large room over a hotel at the corner of David- and Harrington-streets. In 1834 she occupied Cameron's theatre, and in 1840 brought from London an operatic company that performed grand opera there steadily for four years—a remarkable record. It included at one time or another Theodosia Yates (already mentioned), the singer Walter Sherwin, and the dancer Signor Carandini, for whom see CARANDINI, MARIE.

When this company went to Sydney, George Coppin had a successful season in Hobart before taking over the Olympic Theatre in Launceston on 3 March 1845; this was the first regular Launceston playhouse, Cameron's theatre being an upper room of the British Hotel. While in Launceston Coppin organized the company he took to Melbourne the same year—a good company including G. H. Rogers, a genial comedian who later proved himself versatile and accomplished, his wife, who was a sister of Charles Young, and Young and his wife. Rogers came to Hobart as sergeant in a line regiment, and displayed so much talent in amateur theatricals that Mrs. Clarke, the manageress and lessee of the Hobart theatre, bought him out of the service.

At Melbourne in 1841 a wooden pavilion was erected in Bourke-street in connection with the Eagle Tavern, but the magistrate refused a theatrical licence, so only musical entertainments could be given. The place, becoming disorderly, was closed by the police, but was re-opened in 1842 as the Theatre Royal. The first dramatic performance in Melbourne, given as a hospital benefit on 1 February 1842, under the management of George Buckingham, was 'The Widow's Victim' with an afterpiece 'The Lottery Ticket.' The Melbourne Royal was leased by Knowles of the Sydney 'Old Vic.' until 1844; it was then taken over by Cameron of Launceston, whose work gave it a recognized place amongst Australian playhouses. It was closed on 24 April 1845, three days after the opening of the Queen's Theatre, built by J. T. Smith in Queen-street, close to Little Bourke-street. For some months Coppin's company and the Melbourne company played at the Queen's on alternate nights.

In Adelaide Coppin built the first successful playhouse—Coppin's Theatre at Port Adelaide—in 1846 and, later, the Victoria in Currie-street. In Queensland and Western Australia the dramatic tradition is of later origin. The Brisbane school of arts hall, opened on 7 October 1851, was used occasionally for musical and dramatic productions—especially after it was moved to Adelaide-street, where it was successively known as the Bijou Theatre, the Albert Hall and the Gaiety Theatre. In 1856 an attempt was made by W. H. Ford from Astley's Amphitheatre, London, to run a theatre, but it was left to G. B. Mason to establish the theatrical business on a commercial basis by opening Mason's Theatre on 13 December 1865, despite considerable opposition. Soon afterwards the Royal Alexandra Theatre was opened by James Dinsdale, who arranged for the appearance of a 'dramatic and Shakespearean' company, starring J. L. Byers and Julia Hudson. On 21 April 1874 the Queensland Theatre (now the Theatre Royal) was opened, and on 2 April 1888 the Opera House, which is now His Majesty's Theatre. In Western Australia the Perth town hall was used for dramatic entertainments until the opening of the Cremorne Theatre in 1896, and of the Royal in 1897.

The impetus of the gold discoveries was felt in the dramatic as in other spheres of Australian life. The modern history of the drama on an Australian basis may be said to date from the fifties, when the chief Australian towns were visited by a distinguished group of English artists—the Starks, G. V. Brooke (q.v.), Fanny Cathcart, Waller and his wife, Laura Keene, Edwin Booth and William Hoskins. Hoskins, a comedian, during the next 30 years was continually before the Australian public as an actor-manager. The most notable of the group was Brooke; he first appeared in Melbourne at the Queen's Theatre under the management of Coppin. When, however, a portable iron theatre which had been constructed to his order in England (it was 88 feet long and 40 feet wide, and an interesting description of it will be found in the *Year Book of Facts* for 1855) reached Melbourne, Coppin erected it in Lonsdale-street, called it 'The Olympic,' and transferred Brooke to it. In 1856 he shifted the company again, to the Theatre Royal, whose owner had gone bankrupt. When the partnership between Brooke and Coppin was dissolved, Brooke stayed at the Theatre Royal, and Coppin went back to the Olympic, which had been used in the interim as a casino. In 1862 he opened the Haymarket Theatre, with Joseph Jefferson, the American comedian, as the 'star,' and it was to this theatre that he brought Charles Kean and his wife in the following year. The Keans (who were accompanied by James Cathcart, Fanny's

brother) were given a warm welcome by Shakespeare-lovers in Australia, though their best productions were equalled by those of Barry Sullivan (q.v.) who appeared at the Royal under the management of J. Hall Wilton. The sixties were rich in Shakespeare. The Keans were followed in 1866 by William Anderson, and by his contemporary Walter Montgomery, whose interpretation of Hamlet gave rise to a vigorous controversy in the Melbourne press on the subject 'Was Hamlet mad?' When in 1869 Montgomery appeared at the 'Old Vic.' in Sydney, he was supported by George Darrell, whose play 'The Sunny South' had a long run both in Sydney and London, and was the best of his many melodramas. By creating the character part of Babs Berkeley in 'The Sunny South' Essie Jenyns first attracted public notice.

Towards the end of 1874 J. C. Williamson and his wife, always affectionately known as Maggie Moore, visited Australia under the management of Harwood, Stewart, Hennings, and Coppin, and opened in Melbourne with 'Struck Oil,' which was an immediate success. In due course they departed, but in 1879 Williamson returned to Australia and undertook management on his own account. After another successful run of 'Struck Oil,' he introduced to Australia Robert Brough and Florence Trevelyan for his first season of Gilbert and Sullivan opera; his later productions during the eighties had Nellie Stewart as leading artist. Meanwhile Williamson had negotiated a partnership with Arthur Garner, a member of the London Comedy Company which opened in Melbourne on 15 March 1880, and with George Musgrove, a formidable rival who had produced with great success 'La Fille du Tambour Major.' So was formed the 'triumvirate'—one of the most powerful business partnerships in the history of the Australian stage. But the J. C. Williamson company did not dominate the Australian stage during the eighties and nineties as it does to-day. Musgrove after seven years terminated his connection with Williamson, and played his own company with Nellie Stewart as star. George Rignold (q.v.) and Alfred Dampier (q.v.) alternated Shakespeare with melodrama. On his second visit to Australia Rignold negotiated for the building of Her Majesty's Theatre at Sydney, which was opened on 10 September 1880 with a spectacular production of 'Henry V.' With Rignold was associated for a time Kate Bishop (mother of Marie Lohr), whose name is best remembered in connection with his stirring melodramas of the eighties. Rignold's chief melodramatic successes were 'In the Ranks' and 'Lights o' London.' For a long period Dampier staged a Shakespearian play every Friday evening in Sydney—his losses on Shakespeare being made up by his profits on melodrama. His most successful melodramatic production was 'Robbery Under Arms,' dramatized by himself and Garnet Walch from Rolf Boldrewood's novel. But the most brilliantly staged melodramas Australia enjoyed during this period were those of Bland Holt, son of the English actor Clarence Holt; for more than 20 years he produced melodrama on the Drury Lane scale, his work being continued on a less elaborate scale by William Anderson, a prominent figure since the sixties.

Of a higher quality were the productions of the Brough-Boucicault company. Robert Brough and Florence Trevelyan had won immediate popularity under J. C. Williamson's management; when they joined forces with the veteran dramatist Dion Boucicault and his son and daughter, who had been producing Irish plays for the Australian public, their success was assured. In 1887 the company took over the Bijou Theatre at Melbourne and the Criterion at Sydney, keeping the two houses open continuously until 1893. Their earlier productions were of burlesque but in 1888 they turned to good comedy, and for a number of years produced the many high-class plays that were being poured out by Arthur Wing Pinero, Henry Arthur Jones, and their fellows. Under the management of these various companies there appeared in Australia during the latter part of last century a long procession of distinguished actors, beginning with Ristori, the Italian tragedienne, in 1875 and Mrs. Scott Siddons in 1876, and culminating with the appearance of Sara Bernhardt as 'Camille' on 8 July 1891. Among other notable visitors from overseas may be mentioned Wilson Barrett (in 1898 and 1902), Julius Knight (who headed Williamson companies for several years), Cuyler Hastings and Nat Goodwin.

During the period under review the modern variety stage was developed in Australia by Harry Rickards (Henry Benjamin Leete). In 1872 Rickards—vocalist, comedian, and manager—first visited Australia; a second and third visit followed, and in 1893 he took over the Garrick, a theatre erected on the site of the old Tivoli which had been opened in 1868 as the Scandinavian Music Hall, and was for a long time the home of Hancock's Federal Minstrels. Rickards then proceeded to ally himself with managers in all the capital cities, this being a necessary preliminary to the introduction of stars from abroad. He practically controlled the variety stage in Australia until his death in 1911.

Early in the present century the Australian theatre (with the exception of the variety stage) passed under the domination of J. C. Williamson and Company. The period lacked dramatic incident until the organization of a rival company by Meynell and Gunn (later Meynell and Clarke), under whose management Oscar Asche and Lily Brayton opened their Australian tour in 1909. This competition led the older company to introduce H. B. Irving (whose Shakespearean productions were not very successful) and two grand opera companies. Meanwhile Meynell and Gunn secured Ethel Irving (who gave fine productions of 'Lady Frederick' and 'Dame Nature'), and arranged for a second visit from Oscar Asche and Lily Brayton. In 1911 the two firms joined forces. Another revival followed the formation of the theatrical firm of J. and N. Tait (previously concert directors) who introduced Sara Allgood, Emilie Polini, and Guy Bates Post to Australia during the war period; but after a few years of independence this firm in its turn joined the Williamson combination, and another opposition company—Hugh Ward leaving the Williamson firm to join Benjamin and John Fuller, who had previously been engaged in variety work—provided competition and so stimulated the production of popular entertainments. For the most part, however, this stimulus has resulted in an inrush of musical comedies and similar entertainments, though among visitors from England since the war have been Irene Vanbrugh (who first visited Australia with John L. Toole), the younger Boucicault (who had been the kingpin of the old Brough-Boucicault combination), Asche on a return visit, and Seymour Hicks.

Nor must the enterprise of Allan Wilkie be forgotten. For five years continuously he has presented Shakespeare to Australian audiences both in the cities and the smaller towns, recording his thousandth consecutive performance towards the end of 1924; in 1925 his work was rewarded with the grant of a C.B.E.

The Repertory stage.—The first Australian repertory theatre, established in Adelaide in 1908 by Bryceson Treharne as the 'Adelaide Literary Theatre,' grew out of a class formed for the study of dramatic literature in 1907. The name was changed to the 'Adelaide Repertory Theatre' in 1913. In spite of the vicissitudes of the war the society has paid its way from the start and during the 16 years of its existence about 150 plays have been produced. In 1911 Gregan McMahon, one of the ablest of Australian-born actors and probably the best of Australian producers, organized a repertory theatre in Melbourne which so flourished under the patronage of Lord Denman when governor-general that a building was specially erected for it. The war destroyed it, not by removing its audience but by depriving the producer of his best players; but during its seven years' career (1911-17) it was responsible for the production of 57 good plays, 13 of which were written by Australians. Post-war efforts to revive it under the name of the Mermaid Society have been successful, and the old name was resuscitated in 1924. Meanwhile McMahon, who had joined the Taits and moved to Sydney, at the end of 1920 organized a repertory theatre there, and in four seasons (1921-4) produced 24 good plays which would otherwise not have been seen in Australia, three of them being of Australian authorship.

Australian actors and plays.—Until the establishment of repertory theatres in Australia there was no training-school for local histrionic talent —apart from the commercial theatre, where success is hard-won. Nevertheless a number of native-born actors have achieved a local, and a few an international, reputation. Among the latter may be mentioned *Shiel Barry* (see DONOHOE, ANDREW), who after a brief theatrical experience with travelling companies in Australia went to England, where he played with great success. *Howard Vernon* (1845-1921), after making his debut on the Melbourne stage in light Italian opera, toured India and China with G. B. Allen, formed a company of his own which played the same circuit for 4½ years, and then sang in French and English comic opera in England and the United States. During his eastern tour he visited Tokyo in 1877, and was the first European actor to appear on a Japanese stage. In 1880 he returned to Australia to sing in comic opera rôles, and built up an enduring reputation as an interpreter of Gilbert and Sullivan opera, appearing in every play of the series from 'Pinafore' to 'Utopia Limited.' *Oscar Asche*, born at Geelong in Victoria in 1872, was trained for the stage in Norway, went to England in 1893, spent eight years with the Bensons, became manager of the Adelphi Theatre in 1904, and of Her Majesty's in 1907, and then toured the United States, South Africa and Australia (here under the management of Meynell and Gunn, producing Shakespearian plays only). In 1912 he toured Australia again under J. C. Williamson Ltd., producing Shakespeare and the Oriental play 'Kismet,' which he had already played with great success in England. After a tour of South Africa he returned to England in 1915 and the next year produced 'Chu-chin-chow,' famous for its uninterrupted run of nearly five years in London. In 1922 he again visited Australia, bringing a new Oriental drama, 'Cairo,' and reviving earlier successes in Shakespeare and Pinero. *Otto Peter Heggie*, born in 1880 at Angaston in South Australia, after a period of study at the Adelaide Conservatorium of Music, played in melodrama with Julius Knight and in comedy-drama with William Hawtrey; in 1907 he went to England, toured the United States with Ellen Terry, had parts in Shaw's 'Misalliance' and Galsworthy's 'Justice,' and in Shaw's 'Androcles' established his reputation firmly. Since 1913 he has been recognized as one of the six best English actors on the stage.

Of Australian actresses the best-known is *Nellie Stewart* (q.v.), who for many years played with Howard Vernon in Gilbert and Sullivan opera, and afterwards achieved equal success in melodrama of the 'Sweet Nell of Old Drury' type. Towards the end of last century *Essie Jenyns*, a step-daughter of Charles Holloway, began to build up a reputation in Mary Anderson parts, but married and left the stage. *Florence Young* of Melbourne succeeded Nellie Stewart as a comic opera favourite, and *Marie Lohr* and *Madge Titheradge*, though their training and their careers have been mainly English, are Australian by right of birth.

The first written plays published in Australia were three historical dramas and a farce which David Burn published in Hobart and dedicated to Lady Franklin in 1842. Of their production on the stage there is no record. Australian playwrights have so far received little local encouragement except from the repertory theatres, as managers find it more profitable to produce only such plays as have had a successful run in London or New York. A few Australian plays have been produced in London, among them George Darrell's 'The Sunny South' (1884), Alfred Dampier's adaptation of 'Robbery Under Arms' (1894), and Bert Bailey's 'On Our Selection' (1920). Two of these are melodramas, the third a farce. Haddon Chambers (q.v.), though technically an Australian dramatist, spent his adult life in England and never used an Australian setting for his plays. The first Australian-born dramatist to achieve London production was Norman McKeown, whose 'Travellers' was put on by the Stage Society in 1912. Arthur Adams, a New Zealander whose life has been mainly spent in Australia and England, has to his credit the production in 1917 of 'Mrs. Pretty and the Premier' by Arthur Bourchier at His Majesty's Theatre; this play was first staged at the Melbourne repertory theatre. Among plays published but not yet commercially produced may be mentioned those of Montague Grover, Louis Esson, Helen de Guerry Simpson, and George S. Beeby.

J. F.

Draper, DANIEL JAMES (1810-1866), born at Wickham in Hampshire on 28 August 1810 and trained for his father's trade of carpentering. In 1830 he joined the Methodist Church, in 1834 was appointed a minister, and in October was sent to Australia as a missionary. Reaching Sydney on 3 April 1835, he worked for 10 years in New South Wales, in 1846 was made first superintendent of the Adelaide circuit, and in 1855 was transferred to Victoria. In all three colonies his activity was remarkable, and he was responsible for the erection of very many churches and school-houses. Having visited England in 1865 for his health's sake, he em-

barked in the s.s. *London* on 5 January 1866, and was drowned—together with Dr. Woolley, G. V. Brooke, and nearly 250 other passengers—when the vessel went down in the Bay of Biscay on the 11th. A 'Draper Memorial Church' was erected in his honour at Adelaide.

Drongo, Spangled (*Chibia bracteata*), the sole representative in Australia of the drongo family (Dicruridae), members of which are numerous in southern Asia, and occur also in Africa. The spangled drongo is a glossy black bird, with deep metallic green wings and tail, and

Spangled Drongo.

green spots on the feathers of the head and breast; the tail is long, somewhat forked, with the outer pair of feathers recurved. It is common in the north of Australia and New Guinea, and occasionally extends southwards in summer along the east coast to Victoria—even to Tasmania. It is active and noisy; its usual note is a loud harsh cackle, but it also mimics other species. Its food consists mainly of insects. When nesting, it is extremely bold and pugnacious, driving away hawks and crows from the vicinity. The nest, composed of the dry, wiry stems of climbing plants, is an open cup-shaped structure placed at the extremity of the branch of a large tree. The three or four eggs are white, with dark spots.

Drummer, fishes of the genus *Kyphosus*. The Silver Drummer (*K. sydneyanus*) is common round rocky reefs in the neighbourhood of Sydney during the warmer parts of the year, when the rocks between tide-levels are covered with a brown seaweed (*Wildemania*) upon which it feeds. When this dies off during the winter months, most of the drummer likewise disappear, perhaps migrating into deeper water, though young examples are occasionally taken throughout the year. They also feed upon shell-fish and crabs, but are so fond of the weed that, if handfuls of it be thrown into the water, they will rise to it with avidity and partly expose themselves above the surface. They are captured by line-fishermen with hooks baited with the seaweed, but most of those marketed are caught in nets. The silver drummer attains a length of over 30 inches; small specimens are tasty table-fish, but the larger examples are almost worthless as food unless specially treated. It ranges from New South Wales to south-western Australia and New Zealand.

Other species of *Kyphosus* occur in our tropical waters, and one (*K. cinerascens*) is known as 'bream.' All have the head, body, and much of the fins covered with stout scales, and, in conformity with their weed-eating habits, the outer row of incisors in each jaw is modified to form cutting teeth. The Rock Blackfish (*Girel'a*) also is known as 'black drummer' round Sydney.

A.R.McC.

Drummond, JAMES (1787-1863), born in Perthshire, brother of the botanist Thomas Drummond who discovered the well-known *Phlox Drummondi*, is first heard of as curator of the botanical gardens at Cork, Ireland, in 1809. In 1829 he accompanied Captain James Stirling (q.v.) to Western Australia as botanist, naturalist and 'superintendent'—probably of agricultural operations. He took up land on the Swan and Helena rivers near Guildford, devoting part of his time to the curatorship of a botanical garden on what is now Stirling Square in Perth. He also took up a large area of land near Toodyay (on the Swan about 60 miles NE. of Perth) and devoted much attention to fruit-growing there. His interests, however, were concerned with discovering new plants rather than fostering gardens, and he occupied himself mainly with long journeys across country, as far as King George's Sound in one direction and the Murchison River in the other. His discoveries were naturally many and of great value, and his name is attached to over 100 species of plants endemic in Australia. In 1839 he commenced to prepare sets of Western Australian plants for sale to European collectors and gardens; six series in all were issued, and one set of each series placed in Kew Gardens near London. He died at Hawthornden near Toodyay on 27 March 1863. The date of his birth is uncertain. In Stirling's muster-book of 1829 he is entered as 42 years old, which makes his birth-year 1787; but at his death he was reputed to be 79, which would imply his birth in 1783-4. His fourth son, Johnston Drummond, born in 1820, collected birds for John Gould (q.v.) and while doing so was killed by aborigines in 1846.

Dry, SIR RICHARD (1815-1869), born near Launceston in Tasmania on 15 June 1815, was the son of Richard Dry, one of the Irish Exiles (q.v.), who from 1805 to 1818 was so excellent a storekeeper at Port Dalrymple that when he retired in 1819 Macquarie gave him 500 acres and a year's victualling from the government stores. At this time he had 7000 sheep and nearly 400 cattle—'a very large fortune' said Macquarie approvingly—for the maintenance of which the grant was made. The son, educated at Campbelltown in Tasmania, managed his father's estates until in 1844 Eardley-Wilmot nominated him to a seat in the old council; here he fought the governor strenuously on the question of loading the colony with the cost of the convict system, and led the 'patriotic six' non-official councillors who, resigning in 1846, brought about Eardley-Wilmot's downfall. Reinstated

in 1848, he next attacked the whole system of transportation; and, when in 1851 Tasmania acquired a representative form of government, he was elected for Launceston amid great popular enthusiasm. On 30 December of that year he was chosen speaker of the new council, retiring in 1855 on account of ill-health; after a visit to England, from which he returned in 1860, he was in 1862 elected to the council as member for Tamar, and on 24 November 1866 formed a ministry which he led until his death on 1 August 1869. A man of great tolerance and tact, he was probably the most popular politician ever known in Tasmania. (Kt. Bach., 1858.)

Dryandra, a genus of the family Proteaceae, consisting of shrubs, often prostrate or flowering near the base, endemic in Western Australia. The flowers, usually yellow, are in pairs in dense heads within a series of bracts, and usually surrounded by a ring of leaves similar to the stem-leaves; corolla usually straight, with a slender tube, the lobes separating as the tube opens or (rarely) remaining coherent; fruit a compressed capsule, opening at the dilated margin in two leathery, or almost woody, valves; seeds compressed, with a terminal membranous wing, broad and rounded like the valves.

Duboisia, a genus of the family Solanaceae, consisting of shrubs or trees with small flowers and succulent fruits. *D. myoporoides* (Corkwood) ranges from New South Wales into Queensland, and extends to New Caledonia. According to Dr. Woolls (quoted by Maiden in *Useful Native Plants*), this tree 'has an intoxicating property. The aborigines make holes in the trunk and put some fluid in them, which, when drunk on the following morning, produces stupor. Branches of this shrub are thrown into pools for the purpose of intoxicating the eels and bringing them to the surface.' The timber is white to yellowish, close-grained and firm, though soft when green; it is used for carving and wood engraving. The bark resembles that of the Cork Oak (*Quercus suber*) of commerce. *D. Hopwoodi*, the *pituri* plant, an inland species, is endemic in Australia. The aborigines of central Australia masticate its leaves when more or less powdered and mixed with finely broken twigs. So fine is the powder, and so irritating, that even the most careful handling is accompanied by sneezing. The trees are patchy in distribution, but the blacks travel enormous distances to procure it, and it has become a valuable commodity in tribal barter. The tops and leaves are gathered in August, when the plant is in blossom, and hung up to dry, then packed in netted bags or skins for transport. Sometimes *pituri* is chewed in company, a quid being passed from one to another. It is also smoked; for this the leaves are damped, mixed with potash prepared from the ashes of plants, and rolled up in the shape of a cigar. In small quantities it has a powerful stimulating effect, assuaging hunger, and enabling long journeys to be made without fatigue and with little food. The blacks use it to excite them before fighting, and to poison emus. *D. Leichhardti* is also endemic and limited to the eastern States, chiefly Queensland. Recent investigations show that all three species contain atropine, hyoscyamine and other mydriatic alkaloids. See BANCROFT, JOSEPH.

Du Cane, SIR CHARLES (1825-1889), born in 1825 at Ryde in the Isle of Wight, was educated at Charterhouse and Exeter College, Oxford (B.A., 1847; M.A., 1864). Entering politics as conservative member for Maldon (Essex) in 1852-3, he represented North Essex in the house of commons from 1857 to 1868, during the last two years of his term being a civil lord of the admiralty. In December 1868 he was appointed governor of Tasmania, reached the island on 12 January 1869, and served until 28 November 1874. During this time the colony prospered greatly; gold and other metals were discovered, railways were built, and the submarine cable across Bass Strait linked Tasmania up with the mainland. Returning to England at the end of 1874, Du Cane was in 1875 placed on a royal commission to investigate the working of the factory acts. In 1878 he became chairman of the board of customs, and retained the post until his death on 25 February 1889. (K.C.M.G., 1875.)—A cousin, SIR EDMUND FREDERICK DU CANE (1830-1903), a notable reformer of prison conditions in Great Britain, was from 1851 to 1856 employed in Western Australia to organize convict labour on public buildings. He was recalled for service in the Crimean war, but did not reach England till it was over. From 1856 to 1863 he designed harbour defences at Dover and Plymouth, and from 1863 onwards was director of convict prisons, inspector of military prisons, and (from 1873) chairman of the prison commissioners. Born at Colchester on 23 March 1830, he died in London on 7 June 1903. T.D.

Duckett, SIR GEORGE (1725-1822), son of George Jackson of Richmond in Yorkshire, born on 24 October 1725, entered the navy office about 1743, was made secretary to the navy board in 1758, and second secretary to the admiralty on 11 November 1766. From 1766 to 1768 he was member for Weymouth in the British parliament. In 1782, having been implicitly censured by the house of lords for irregular procedure in connection with a court martial, he left the admiralty (becoming simply judge-advocate of the fleet), and in 1788 and 1791-6 was member for Colchester. In 1797 he assumed the name of Duckett by royal licence to conform with the conditions of a bequest from his second wife's uncle. He died in London on 15 December 1822.

His connection with Australia results from his long-continued patronage of James Cook, who began life as a stable-boy on the estate of Jackson's sister at Ayton in Yorkshire; it was probably his influence with Lord Sandwich that gave Cook command of the *Endeavour*, and Cook recognized his help by naming after him Port Jackson in New South Wales and Point Jackson in New Zealand. The fact that Jackson afterwards changed his name allowed his eponymity to drop out of sight, and a legend arose (and was believed by Dr. Lang) that Port Jackson had been named after a seaman who sighted it from the *Endeavour's* masthead. As there was no one of the name of Jackson in the *Endeavour's* crew, this explanation is obviously impossible. Duckett's claim to be the godfather of Sydney harbour rests on (*a*) a specific statement to that effect on his tombstone in the church at Bishops Stortford, England, (*b*) the indirect evidence that Points Jackson and Stephens in Admiralty Bay, New Zealand, were according to Cook's own journal named after the then joint secretaries of the admiralty, and that shortly after naming Port Jackson in New South Wales Cook named Port Stephens, thus a second time associating the two men. (Bart., 1791.)

Ducks and Geese, aquatic birds belonging to the order Anseriformes, found throughout the world and represented in Australia by 18 species. Though most of the members of the order may be readily classed as geese or ducks, certain forms are so nearly intermediate that it is usual to regard them all as members of the single family Anatidae, which also includes the swan (q.v.).

Australian geese are of peculiar types. The Cape Barren Goose (*Cereopsis novaehollandiae*), a gray bird with a wax-yellow shield above the

Cape Barren Goose.

beak, was first discovered in 1792, when the French naturalists of d'Entrecasteaux's expedition in search of La Pérouse found it on the islands of the Recherche Archipelago in Western Australia. It derives its popular name from Cape Barren Island, one of the Furneaux group in Bass Strait, where—as in many other islands off the southern coast of Australia—it is found in numbers; although webfooted, it is never seen on the water, but feeds on the island grasses and herbage. When these dry up, it migrates to the mainland of Australia or Tasmania to feed, but always returns to the islands to breed.

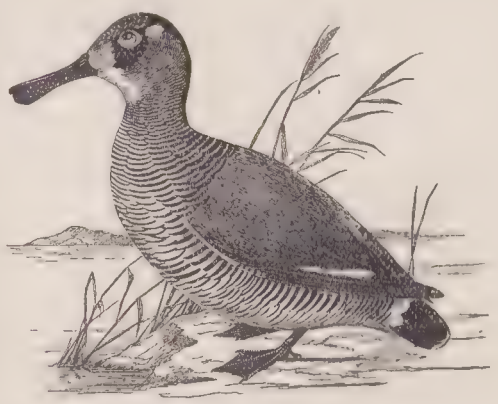
The Magpie Goose (*Anseranas semipalmata*) was formerly found throughout northern and eastern Australia, but is now almost extinct in the settled districts of the south-east. The webs of the feet only extend a short distance along the toes, leaving the extremities of the latter free.

Two species of Pygmy Geese or Goose-teals (*Cheniscus*) occur in Australia, one in the north and the other in the east. Though true geese in form, they are smaller than teal.

Maned Goose.

The Maned Goose or Wood Duck (*Chenonetta jubata*)—which is, as its alternative names imply, intermediate between geese and ducks—is widely distributed throughout Australia and Tasmania, and must be regarded as another of our peculiar endemic Anatidae.

Of the Australian ducks the commonest—and most sought after by sportsmen—is the Black Duck (*Anas superciliosa*), which occurs also in New Guinea and New Zealand; it is nearly allied to the wild duck of the northern hemisphere (*A. boschas*), from which our domestic ducks are derived, and with which it readily interbreeds in confinement. It is, however, remarkable that in the black duck the sexes are alike, both resembling the female of the northern species, whilst in *A. boschas* the drake assumes brilliant colours in the breeding season. Other well-known Australian ducks are the two species of Teal (*Virago*), the Blue-wing or Shoveller (*Spatula rhynchotis*), the Mountain-duck or Sheldrake (*Casarca tadornoides*), and the Hardhead or White-eyed Duck (*Nyroca australis*), all members of genera widely spread throughout the world. But three Australian ducks are sufficiently peculiar to be regarded as generically distinct from anything found elsewhere. These are the Freckled Duck (*Stictonetta naevosa*), a rare species generally found sparingly in flocks of other ducks; the Pink-eared Duck (*Malacorhynchus membranaceus*), a species the size of a teal, with a very wide shovel-shaped bill; and



Pink-eared Duck.

the Musk Duck (*Biziura lobata*). The last was first met with by Vancouver in 1791, in King George's Sound in Western Australia. He notes in his journal that 'though ducks were in great numbers, we were very unsuccessful in taking them. A very peculiar one was shot, of a darkish-grey plumage, with a bag like that of a lizard hanging under its throat, which smelt so intolerably of musk that it scented nearly the whole ship.' The 'bag' mentioned by Vancouver is a membranous flap projecting from the chin, which in old males attains a large size; its use has not been ascertained. The musk duck is plentiful on swamps, rivers and inlets of the sea throughout southern Australia and Tasmania. When pursued it takes refuge in diving—very few persons have ever seen a musk duck flying. It can, however, fly strongly, but rarely does so except at night, when travelling from one swamp to another.

Dudley, Earl of. William Humble Ward, 2nd Earl of Dudley, born on 25 May 1867 and educated at Eton, succeeded his father in the earldom in 1885 and from 1895 to 1902 was parliamentary secretary to the board of trade, serving during that period with the yeomanry in South Africa (1899-1900). From 1902 to 1906 he was lord-lieutenant of Ireland; in 1906-8 chairman of a royal commission on congestion in Ireland; from 1908 to 1911 governor-general of Australia—and took great interest in the discussions that determined Australia's contribution to Imperial defence. In 1915 he commanded the Worcester yeomanry on the Gallipoli peninsula, and later on was commandant at Mudros, while in 1916 he was attached to the headquarters staff of the 40th division. (G.C.V.O., 1903; G.C.M.G., 1908; G.C.B., 1911.)

Duelling. For fifty years after Australia was first settled the duel was still in Great Britain a recognized mode of settling a quarrel, and the leading men of the distant colony conformed to the custom. Indeed, it survived in Australia after it was extinct in Britain, for the last duel fought in England took place in 1845, the last in Ireland in February 1851, and the last in Australia in September 1851.

Three Australian duels are of some historical importance. On 10 September 1801 William Paterson, then in command of the New South Wales Corps, challenged his junior officer John Macarthur for having divulged and misinterpreted Paterson's private communications to him. On the 14th they met near Parramatta, and Macarthur, obtaining first fire, wounded Paterson in the right shoulder so severely that the colonel was rendered unable to fire in his turn. Governor King promptly had Macarthur arrested, together with the seconds, Captains Piper and McKellar; Macarthur demanded a court martial, and King—knowing that feeling ran so high among officers of the corps that an impartial trial by them was impossible—sent him to England to be tried there. The full story of the duel will be found in vol. iv of the *Historical Records of New South Wales.* Only King's intervention prevented a duel between Piper (Macarthur's second) and McKellar.

Between 1801 and 1826 public feeling about duelling had begun to change, and the duel between Saxe Bannister and Robert Wardell was an extremely inconspicuous affair. Wardell, as editor of *The Australian* (a newspaper opposed to Darling and his officials), on 18 October 1826 made a bitter attack on Bannister, who had just resigned the attorney-generalship. The attacked man asked Darling to prosecute the offender; Darling refused, since Bannister was no longer an official; and Bannister promptly challenged Wardell. They met at Pyrmont on 21 October, exchanged shots that hurt only their clothing, and were then persuaded off the field by their seconds. It is noteworthy that, whereas King had filled many pages of foolscap with the details of the Macarthur duel, Darling does not appear to have mentioned the later one. Writing on 1 November, he merely says:—'I might add that the rancour of the Editor and Mr. Bannister against each other appears unparalleled.'

The third duel, 25 years later, created a much bigger sensation. In September 1851 Stuart Donaldson—who had been for three years an elected member of the legislative council of New South Wales, but was at the moment a candidate for election—attacked the government of the day for extravagance and cited as an example over-expenditure in the surveyor-general's department. Sir Thomas Mitchell, who was head of the department, attacked Donaldson in the *Sydney Morning Herald,* and after much bickering the offender declared that he was blaming the whole system of land administration, not the surveyor-general's department in particular. This failed to appease Mitchell, who sent a friend to him to arrange a duel. On the 27th the two met in the bush near what is now Centennial Park, Sydney; each fired three shots, Mitchell's last going through Donaldson's high hat; and the seconds then put an end to the fight.

Two duels that did not take place may be recorded. In 1844 Robert Lowe (see Sherbrooke, Lord) was challenged by Henry McDermott, an alderman of Sydney, but merely brought the challenger into court and had him bound over to keep the peace. In 1849 Lowe was in trouble again—his bitter tongue, indeed, would in earlier days have brought him into many duels. Wentworth's first (1849) bill for the incorporation of a university at Sydney included a clause appointing William Bland, among others, to the university senate. In committee of the council on 5 October the bill was 'counted out;' when on the 10th Wentworth moved to recommit it, Lowe attacked it for allowing an ex-convict to become a senator. On the 11th Bland wrote to Lowe a letter which is now in the Mitchell library, not challenging him in set terms ('I am recommended not to call upon you for the satisfaction of a gentleman, because you have on more occasions than one . . . . in a manner the most cowardly evaded it'), but merely calling him a coward and a scoundrel if he did not fight. Lowe attempted to prosecute Bland for 'inciting deponent to commit a breach of the peace,' but the judges decided that there was not sufficient evidence of incitement—apparently thinking that no insults could incite Lowe to a breach of the peace—and the affair ended.

Duelling in India provided Australia with at least two good colonists—George Bridges Bellasis and William Bland. Bellasis in May 1801 killed the man who had jilted his sister-in-law and slandered the Bellasis family; on 18 July he was sentenced at Bombay to 14 years' transportation; on 2 January 1802 he reached Sydney in the E.I.C. cruiser *Fly,* and was at once conditionally pardoned by King and appointed on 14 October lieutenant of artillery with charge of the fixed defences of the colony, succeeding Francis Barrallier. In November 1803 he received a full pardon, and returned to India. For Bland's duel see Bland, William.

Duff, Sir Robert William (1835-1895), born at Fetteresso in Kincardineshire on 8 May 1835 and educated at Blackheath, entered the navy in 1848 (sub-lieutenant, 1854; lieutenant, 1856; commander, 1865), but took up politics in 1861, and from that year to 1893 was liberal member for Banffshire. From 1882 to 1885 he was liberal whip, and in the short Gladstone ministry of 1886 was a junior lord of the admiralty. In 1892 he was made a privy councillor for long-continued and unostentatious services both to his party and to the country. On 23 February 1893 he was appointed to the governorship of New South Wales, and used his wide knowledge of parliamentary practice to solve several difficult situations due to the impetuosity of his premier, Sir George Dibbs. His

term of office was troubled in several ways, and on 15 March 1895 he died at Sydney. His surname at birth was Duff-Abercromby; but he discontinued the use of the latter portion in 1870 on succeeding to the ownership of the Fetteresso estate. (G.C.M.G., 1893.)

Duffy, Sir Charles Gavan (1816-1903), born in county Monaghan, Ireland, in 1816 and educated at Belfast, in his 20th year became subeditor of the Dublin *Morning Register*, three years later owned and edited the Belfast *Vindicator*, and in 1842 returned to Dublin to join John Dillon and Thomas Davis in starting the *Nation* as the organ of Young Ireland. Working with O'Connell 'the Liberator,' he was convicted of sedition in 1844 (but escaped on a technical point), founded the Irish Federation in 1846, was arraigned four times for treason-felony in 1848-9 (the juries always disagreed), and in 1852 revived the *Nation* (which had been suppressed), helped to found the Tenants' League (an organization in which Ulster Protestants and Catholics from the south of Ireland worked side by side), and was elected to the British parliament as a member of the Independent Irish party. When that party broke up in 1855, Duffy left parliament in disgust and migrated to Victoria, reaching Melbourne in January 1856.

By this time he enjoyed a great reputation in politics. Latrobe, Robert Lowe, and the Howitts had combined to praise Australia to him and him to Australia. He was hailed by the large body of Irish colonists as their destined leader; O'Shanassy at the head of a eulogistic deputation boarded the vessel that brought him out, and Henry Parkes and Dr. Lang tried to secure him for Sydney. But Duffy preferred Victoria, where his admirers bought him an estate and had him elected to the legislature by a far western constituency. This was the first legislature under responsible government, and Duffy, in close alliance with O'Shanassy, soon made himself prominent; within four months of the opening the two took office for a turbulent six weeks (March-April 1857), were ejected, fought their successors bitterly for another ten months, and on 10 March 1858 resumed office under the nominal leadership of H. S. Chapman. The burning questions at this time were connected with (*a*) extension of the franchise and (*b*) the disposal of crown lands; on both questions Duffy and his colleagues were for radical reform—adult franchise, breaking up the big estates leased to squatters. But before the end of 1859 O'Shanassy and Duffy had parted company, probably because the latter was vain and inclined as a former member of the British parliament to patronize colonial legislators; and the ministry, though it carried its franchise proposals, failed to pass any land legislation and was rejected by the new parliament that met in October. For two years Duffy was in opposition, but on 14 November 1861 again took office as minister for lands under O'Shanassy, with whom a reconciliation had been patched up. During the next 19 months he succeeded in passing a land act that was a genuine but ill-considered attempt to place farmers on soil suitable for farming; but the consequent revaluation of squatters' runs proved disappointing, and caused the downfall of the ministry. During the term of the McCulloch ministry which followed—and which held office with one slight intermission for over six years—Duffy visited Britain, but in 1867 returned, became member for Dalhousie, and by persistent attacks drove McCulloch from office in September 1869, though refusing to replace him. The treasurer of the next ministry was Graham Berry (q.v.), whose protectionist views were gaining great popularity; and, when in June 1871 Duffy at last saw his way to the premiership, he at once took in Berry as treasurer and identified himself with the supporters of a high tariff, adding of his own accord a proposal for progressive land taxation. Carrying the first proposal and losing the second, he was ejected from office in the following June on a charge of favouring his fellow-countrymen and co-religionists when making official appointments. By now he was ageing after a strenuous career, and never held office again; when the protectionists again came into office it was Berry who led them, and Duffy went off to England once more. Returning in 1877, he declined to serve under the now repentant Berry, but was made speaker of the assembly. In 1878 he refused (after dallying with it) Berry's offer to take him on the famous 'embassy;' at the end of 1879 he resigned his position and retired from politics, returning to Europe next year and for the rest of his life residing in the south of France. From this retreat he poured out a succession of volumes on Irish history and articles on colonial and Irish politics, followed in 1898 by an autobiography, *My Life in Two Hemispheres*. He died at Nice on 9 February 1903. (Kt.Bach., 1873; K.C.M.G., 1877.)

His eldest son, John Gavan Duffy (1844-1917), born at Dublin on 15 October 1844 and educated at Stonyhurst and the university of Melbourne, was for many years prominent in Victorian politics, being minister for lands under Service (March to August 1880), postmaster-general under Munro (November 1890 to February 1892), attorney-general for two months under Shiels (February to April 1892) and postmaster-general again under Turner (September 1894 to December 1899). He represented Victoria on the federal council of 1893 and at the premiers' conference of 1896. He died on 8 March 1917. The second son, Frank Gavan Duffy, born in Dublin on 29 February 1852, is a justice of the federal high court; and the third, Charles Gavan Duffy, born in Dublin on 27 August 1855, entered the Victorian public service in 1871 as private secretary to his father, then premier, was made clerk assistant of the Victorian assembly in 1891, clerk assistant in the federal senate in 1901, transferred to the clerkship of the house of representatives in July of the same year, and in February 1917 returned as clerk to the senate. He retired from the public service in August 1920. (C.M.G., 1904.)

Dugong, vernacular name of a genus (*Halicore*) of marine mammals of the order Sirenia, inhabiting certain areas in the Indian and Pacific oceans and waters connected with them. The separation of the Australian dugongs, as a species distinct from those which inhabit the Indian Ocean and Red Sea on the one hand and the coast of East Africa on the other, has never been justified by the production of any constant differences, either in external features or anatomical structure. In the absence of any evidence of such differences, all existing dugongs must be regarded (at least provisionally) as members of one species. For this Gmelin's specific name, *H. dugong*—given in 1788—is to be preferred by virtue of priority over the other names (*H. australis, H. tabernaculi*) that have been proposed. On Australian

coasts the dugong is at the present day almost confined to the tropics, though ranging from Moreton Bay on the east to the neighbourhood of Broome on the west. On the evidence of an incomplete skeleton, found at a depth of a few feet during the excavation of the canal at Shea's Creek near Botany Bay, it is concluded that the dugong's southward range was more extensive in the past; further evidence in the same direction has been supplied by the discovery of isolated bones at the Macleay River. About 1894, too, a complete specimen is said to have been obtained at Broken Bay. But a much earlier record is the statement of Collins (*Account of the English Colony in New South Wales*, p. 409) that in March 1795 'some of the head bones of a marine animal,' which Paterson said were those of a manatee, were found 'to the southward of Botany Bay.' As the manatee occurs only in the Atlantic, these must have been bones of the allied mammal, the dugong.

The food of the dugong consists, not of algae, as is sometimes stated, but of the roots of certain monocotyledonous plants (*Posidonia, Zostera*) with blade-like leaves ('sea-grass') that give rise to marine 'meadows' on sheltered flats covered with a mixture of sand and mud, and extending from about low water to a depth of several fathoms.

The dugong is a gregarious animal, herds of from 6 to 40 being common; it is recorded that in July 1893 a herd seen in Moreton Bay extended over a length of nearly three miles by a width of 300 yards. The females in any herd always outnumber the males. Aborigines hunt the animal for food, Europeans (who in northern waters employ aborigines, farther south do their own hunting) for the sake of (*a*) the oil contained in the internal fat, which has medicinal value, especially for lung complaints, (*b*) the hide, which when well-tanned makes excellent leather, and (*c*) the bones, which are said to make the best charcoal for sugar-refining. In Moreton Bay and Wide Bay capture is effected by means of strong coir nets of at least 3-ft. mesh (measured diagonally), usually 360 feet long and about 26 feet deep: these are set at low tide at a sharp angle across gutters on the feeding-grounds. The winter months (June, July, and August) form the netting season. Farther north the aborigines follow the dugong in bark canoes, and spear it with heavy harpoons: in the far north—Torres Straits and the waters east of the Cape York peninsula—a light wooden staging set up in places where the animal has been seen to feed is often used instead of a canoe. Among the northern tribes females are strictly forbidden to look at a dugong until it has been cut up, but in southern Queensland this *tabu* no longer exists.

The dugong, as far as is yet known, bears one baby a year. The baby is about three feet long when born, and is suckled through a nipple two inches long situated just beneath the flapper on each side. The mature animal is from 1000 to 1200 lb. in weight, and a specimen caught in Moreton Bay measured 11ft. 8in. from snout to tail; eight to ten feet, however, is a more usual length. A well-grown dugong yields four to five gallons of oil; its hide when green weighs nearly 200 lb.; and the flesh, if treated like pork or bacon, is extremely savoury and digestible.

See A. W. Scott's *Mammalia, Recent and Extinct*, and W. Saville Kent's *Great Barrier Reef of Australia*.

W.A.H.

Dumaresq, HENRY (1792-1838), the eldest of three brothers—descendants of an old Jersey family (the name is pronounced 'Dumarrick' or 'Dumerrick')—who migrated to Australia when their brother-in-law General Darling was made governor. Henry was educated at the royal military college, entered the army at the age of 16 (lieutenant, 1808; captain, 1813; brevet-major, 1815; lieutenant-colonel, 1817) took part in six battles of the Peninsular war, and served on Wellington's staff at Waterloo. He was Darling's military secretary during his administration of the Mauritius (1819-24) and was sent ahead of him to Australia. Reaching Sydney on 13 October 1825, he first busied himself in making the Sydney government house fit to live in (Brisbane had lived at Parramatta), and on 21 December became Darling's private secretary, a post which he held with one intermission until 1831. In 1826-7 he was clerk to the executive council, but in June of the latter year was sent to England with despatches, met the directors of the Australian Agricultural Company (in which he had become interested through the Macarthurs), and impressed them so favourably that at a later date they chose him to succeed Sir E. Parry as commissioner in Australia. He took over the position on 19 March 1834, and proved so efficient that the directors raised his salary and proposed to extend his term of office; but on 5 March 1838 he died at Port Stephens of an apoplectic stroke. From 1831 to 1834 he seems to have lived on his estate at St. Helier's near Muswellbrook on the Hunter River.

WILLIAM JOHN DUMARESQ, the second brother, was educated at the military college, joined the army in 1808, fought through the Peninsular war and the Waterloo campaign, and rose to be a captain in the Royal Staff Corps. Coming to Australia with Darling in 1825, he was made provisionally civil engineer for the colony and (a little later) inspector of roads and bridges, and was recommended for appointment as deputy-surveyor-general; but the British authorities had another man in view for that post, and Dumaresq refused a permanent appointment as civil engineer, though he continued for some time to discharge the duties of that post, and was instrumental in procuring the adoption of the Sydney water-supply scheme devised by John Busby (q.v.). In 1829 he was for a short time acting colonial treasurer and in 1829-31 a member of the land board, but retired into private life in 1831 and settled at Invermein near Scone. He also leased 65,000 acres at Tilbuster, which with Henry Dumaresq's 100,000 at Saumarez completely enclosed Armidale. When elected members were admitted to the legislative council, he represented his district as long as that council lasted (sitting for the counties of Hunter, Brisbane and Bligh in 1843-8, and for Phillip, Brisbane and Bligh in 1851-6), and was nominated to the non-elective council of 1856, but resigned almost immediately. He died at Cleveland in Queensland on 9 November 1868.

EDWARD DUMARESQ (1802-1906), the third brother, was also educated at the military college, and obtained a commission in the engineers; afterwards he served for five years in the survey department, East Indies. By virtue of this experience he was put in charge of the Tasmanian surveyor-general's department by Darling when he called at Hobart on his outward voyage in December 1825. Arthur,

who formed a high opinion of him, confirmed Darling's choice, and further made him a member of the land board and chief commissioner for the survey and valuation of lands. One of his reports stated that New Norfolk should have been the capital of the colony, since it was far more conveniently situated than Hobart for communication with the rest of the island, but admitted that the transfer was at that late date impossible. In 1829 he left the survey office, the British government having never confirmed the appointment and having made a new choice; in 1830 he was made police magistrate at New Norfolk, but in 1833 moved to Longford, and died there on 23 April 1906 at the age of 104. The Dumaresq river in northern New South Wales was so named by its discoverer Allan Cunningham, not after any particular member of the family, but 'in honour of the family to which His Excellency the Governor is so intimately connected.'

Dumaresq, JOHN SAUMAREZ (1873-1922), grandson of W. J. Dumaresq (see DUMARESQ, HENRY), was born at Sydney on 26 October 1873 and named Saumarez either from the old family estate in Jersey or after Sir James Saumarez, under whom a great-uncle served during the Napoleonic wars. Following the example of several ancestors, and an uncle (A. F. C. Dumaresq, son of Henry), he in 1886 entered the navy (lieutenant, 1894; commander, 1904; captain, 1910; commodore, 1919; rear-admiral, 1921). Specializing at first in torpedo work, he later on invented instruments for improving gun-fire control and for determining the rate of movement of enemy ships which proved invaluable in war. At Jutland he commanded H.M.S. *Shannon,* but in 1917 transferred to H.M.A.S. *Sydney,* then cruising in the North Sea, and for a considerable time acted as senior officer of the 2nd light cruiser squadron; he was largely responsible for the carrying of aeroplanes in light cruisers, the first revolving platform being made to his design and fitted in the *Sydney* in October 1917. On 21 March 1919 he was appointed to the command of the Australian fleet, and devoted himself energetically to building up again the efficiency and esprit de corps of a squadron which had during the war been scattered all over the world; and to the last day of his command he protested vigorously against the severe reductions in strength which for political reasons were thought necessary. At the end of his three years' term he hauled down his flag, intending to return to England. On the way, however, he became seriously ill, and died at Manila on 22 July 1922. (M.V.O., 1908; C.B., 1916; C.V.O., 1820; Naval A.D.C. to the King, 1921.)

Dunbar, Wreck of the. On 31 May 1857, the ship *Dunbar,* 1321 tons register, 1980 tons burthen, left England under command of James Green, with 63 passengers and a crew of 59, all told, carrying a full general cargo for Sydney.

Between 7 and 8 p.m. on 20 August she very slowly passed Botany Bay, in an ESE. gale with heavy squalls, showers of rain and rough easterly sea. The land was in sight at an estimated distance of about eight miles, actually, it is probable, not more than six, for in such weather an error of a few miles might easily be made. She stood on, heading about NNE. close-hauled on the starboard tack, under fore-sail and close-reefed fore and main topsails. The revolving light on the south head of Port Jackson was frequently seen between the showers; but the night was very dark, the land was no longer visible, weather conditions grew worse and the ship made several points of leeway, so that her true course would be about NNW. and her speed only three miles per hour.

Shortly after 11.30 p.m., when South Head light was a point or two abaft the beam, the *Dunbar* was probably reckoned to be about six miles outside the entrance to the port (actually she was within two miles). All hands were called on deck and the ship was kept away to the westward for the entrance, running before the wind with her yards almost square and the South Head light slightly on her port bow. The foresail was hauled up and a very sharp look-out kept for North Head, which was not seen; a few minutes later, however, breakers were seen right ahead. At once the master knew he was close in to Outer South Head, ordered the helm to be put hard a-port and the yards braced sharp up on the starboard tack, in hopes of clawing off the land again to the north-eastward, and his orders were promptly carried out. But, with wind and sea setting her strongly to leeward, the ship was too close in and carried too little sail, and, though she started to turn to the northwards, about two minutes later (shortly after midnight) her port bow struck the rocks and she was hurled almost broadside on to the cliffs just north of the signal station, midway between the lighthouse and the Gap.

With the first shock the topmasts went overboard. Directly afterwards the sea broke over her starboard side, carrying away people, boats, bulwarks, and masts, and in a very short time she had crashed to pieces. There was only one survivor, a young able seaman named James Johnson, who had been on deck since 8 p.m.; and it is from his clear and intelligent evidence, given at the inquest held four days later, that the above account has been obtained.

Next day floating wreckage showed that a vessel had been wrecked. Her position was soon found, and many bodies were seen being dashed about by heavy seas, the sprays from which drenched men on top of the cliffs. On the following day Johnson was seen and rescued, having spent some 36 hours on a ledge of the cliffs; and during the succeeding days wreckage of all description, with numbers of mutilated bodies, was found scattered along the beaches of Middle and North harbours. At the inquest, held on 24 August, the jury's verdict was that 'there may have been an error in judgment in the vessel being so close to the shore at night in such bad weather, but they do not attach any blame to Captain Green or his officers for the loss of the *Dunbar.*'

In 1910 a number of relics—anchors, cable, chainplates, copper bolts, coins, etc.—were obtained from the wreck, and are now preserved in the adjacent suburb of Watson's Bay.

In the popular idea that the *Dunbar* was lost because her captain had somehow mistaken the small indentation called the Gap for the mile-wide entrance to Port Jackson there is neither a vestige of truth nor the remotest probability. Green may have attempted to run into the port on such a night because he knew, from the leeway the ship was making, that she could not possibly weather the land but must inevitably be blown ashore and wrecked within a few hours; hence his only chance for

safety was to run into port and anchor. Had he continued only one mile farther to the northward before rounding for the entrance, he would have taken his ship safely in, and this slight error in reckoning was most probably due to the current setting to SSW. F.J.B.

Dunlop, JAMES (1793-1848), born at Dalry in Ayrshire, Scotland, on 31 October 1793, at the age of 14 was employed in a thread factory at Beith, and while there attended a night school where he made a lasting friendship with John Dunmore Lang (q.v.). About 1810 he began experimenting with lathes, telescopes, and reflector-casting; and in 1820, on his return to Beith from Dalry (where he spent two years as a handloom weaver), he met Sir Thomas Brisbane (q.v.), who had a private observatory in the neighbourhood. When Brisbane was appointed to the governorship of New South Wales he selected Carl Rümker (q.v.) and James Dunlop to accompany him as assistants for the observatory he proposed to establish in the colony. The party arrived in Sydney on 7 November 1821; an observatory was at once erected at Parramatta, and the two assistants worked together until 1823, when Rümker left the observatory. Dunlop then carried on the work alone until March 1826, when, Brisbane having left the colony, the observatory was abandoned. An account of the work done in it is given under ASTRONOMY. Dunlop continued his astronomical survey at his home in Parramatta until 4 February 1827, when he returned to Scotland to Brisbane's new observatory at Makerstoun on the River Tweed. He accompanied Brisbane on several continental tours in connection with astronomy, and from 1827-9 contributed papers to the *Edinburgh Journal of Science*. On 6 February 1828 he was awarded the gold medal of the Royal Astronomical Society of London, and subsequently received various European honours. Having in 1830 been appointed by the colonial office to be superintendent of the government observatory at Parramatta, he returned to the colony on 6 November 1831, and until 1839 made regular observations, most of his work being recorded in eight manuscript books preserved at the Sydney observatory. In September 1833 he discovered a comet, and was awarded a gold medal therefor by the King of Denmark, but the British astronomer-royal of the time (Francis Baily) apparently forgot to send the medal out; it was found in 1845 among Baily's effects after his death, and Dunlop received it in November of that year. From Sydney he sent many papers to the Royal Astronomical Society of London, and in 1835 became a corresponding member of the Institut de France. After 1839 he suffered frequently from ill-health, and in November 1847 resigned his position and retired to his farm at Boora Boora on Brisbane Water; there he died on 22 September 1848.

See his biography in Service's *Thir Notandums, being the Literary Recreations of Laird Canticarl of Mongrynen*, published in 1890.

Dunne, ROBERT (1830-1917), born at Lismore in Ireland, and educated at the Irish College in Rome, was professor for a short time at St. Laurence's school, Dublin, and in 1863 came to Brisbane; there he worked as a missionary priest under Bishop O'Quinn, becoming successively secretary and administrator of the cathedral, pastor of Toowoomba, and vicar-general of the diocese. On 18 June 1882 he succeeded Dr. O'Quinn as bishop of Brisbane. He acted as secretary to the plenary council of Australasia held at Sydney in 1885. At the petition of this council Queensland was erected into an independent ecclesiastical province, with Brisbane as the archiepiscopal see, and on 10 May 1887 Dr. Dunne was constituted its first archbishop. During his episcopate schools, convents, and churches were erected with great rapidity; after ten years' administration he had erected or completed 41 churches. On 26 February 1912 the aged archbishop was given the assistance of a coadjutor, Dr. Duhig. He died at Brisbane on 13 January 1917, and was succeeded by his coadjutor. E.M.O'B.

Dutton, FRANCIS STACKER (1816-1877), born at Cuxhaven in Germany in 1816, and educated in Switzerland, adopted at first a mercantile life and spent five years (1833-8) in the employ of a firm in Rio de Janeiro, Brazil. In 1839 he migrated to New South Wales to join two brothers who had taken up land beyond Bowning on the Murrumbidgee and Tumut rivers. Bush life, however, did not for the moment appeal to him, and he crossed to Melbourne and resumed commercial work there for two years. In 1841 he went to South Australia, where his brother Frederick (who had left New South Wales for South Australia in 1839) procured him a post as overseer on Charles Bagot's Kapunda run. Here in 1843 he discovered a copper lode, and he and Bagot were at first joint owners of the Kapunda mine; but in 1845 Dutton sold his interest in it to an East Indies firm, and went back to pastoral life. In 1851-7 he was a member of the South Australian legislative council, and with John Baker and G. S. Kingston (q.v.) led the opposition to the governor's general policy, especially in connection with the new constitution; his special contribution to the constitutional debates was a strong advocacy of vote by ballot. In the legislative assembly of 1857 he was one of the six members for Adelaide city, and held the seat until 1865. In September 1857 he joined the Hanson ministry as commissioner of crown lands, but resigned in 1859; he held the same office in his own short-lived ministry of 1863, but in his second ministry (1865) was commissioner of public works (this was that remarkable period of South Australian history when there were six ministries in 27 months, Henry Ayers being a member of all of them and John Hart and Richard Andrews of four). In September 1865 Dutton left politics to take the agent-generalship for his colony in London, and held the position till his death on 25 January 1877. He was the author of a useful book on the early days of the colony, *South Australia and its Mines*, published in London in 1846. (C.M.G., 1872.)

Dutton, WILLIAM (1809?-1878)—by some authorities confused with William Hampden Dutton, brother of the Francis Dutton just dealt with—was born in Sydney, probably in 1809, taken while still an infant to Tasmania by his parents, and at the age of 18 entered aboard a whaler. In 1828-33 he was serving in various vessels engaged in sealing at Portland Bay, and according to his own account built a house there in 1829 and lived in it for nearly two years in all; on this ground he in 1873 claimed to be the first permanent settler on Victorian soil, antedating the Hentys (q.v.) by five years. In 1833, returning to Portland Bay as master of the whaler *Henry*, he enlarged his establishment to include a vegetable garden, and

his claim to priority as against the Hentys (who first settled there in November 1834) really depends on the question whether this amount of cultivation can be considered a *bona fide* settlement. From 1834 onwards Dutton's connection with the Bay was tenuous; he was commanding vessels owned by a Tasmanian firm in which James Henty was a partner, and was sent to other fisheries, paying only five visits to Portland Bay between 1833 and 1845. By 1851, however, he had abandoned the sea and settled at Narrawong near the head of the Bay, and there he died in July 1878.

Dysoxylon, a large genus of the family Meliaceae, consisting of trees, spread over tropical Asia and Malaysia and extending to New Zealand. Thirteen species are indigenous to Australia. *D. Muelleri* (Red-bean), is a large tree, with a bark emitting a strong odour like that of a swede turnip; the timber is fit for the same purposes as Spanish mahogany. *D. Fraserianum* (Rosewood, so called because of the sweet and persistent perfume of the timber) is a large tree, 70-100 feet high and 4-5 feet in diameter. Its timber is used for indoor work of all descriptions in the building trade, especially for flooring ball-rooms, for which purpose it is said to equal tallow-wood. *D. rufum* (Bastard Pencil Cedar) is a large tree, whose flowers and fruits have an onion-like, almost fetid smell. The timber is soft and fissile, belonging to the cedar class. All three are coastal brush trees, extending from the northern rivers of New South Wales into Queensland.

E

Eagar, GEOFFREY (1818-1891), born in Sydney in 1818 and educated at W. T. Cape's school, was up to his fortieth year engaged in commerce and banking, diversified by writing for the *Monitor* and the *Empire*. On 13 September 1859 he was nominated to the legislative council, and was secretary for public works in the brief Forster ministry of 1859-60. He left the council in November 1860, but on 8 January 1863 was returned to the legislative assembly by West Sydney, and in October joined the first Martin ministry (1863-5) as colonial treasurer, resuming the same post in the second (1866-8). During his third ministry (1870-2) Martin made Eagar—whose financial knowledge had been of great use to him—under-secretary of finance and trade; this position he held until February 1891, when he retired, dying on 12 September of that year. During his second treasurership he advocated the establishment of a national bank with a State note circulation, and aided his leader Martin to negotiate with the Victorian government an amicable arrangement of border tariffs.

Eagle-rays, members of the family Myliobatidae, having sharp, angular, wing-like expansions of the body-disk, which, together with their somewhat bird-like heads, are responsible for their vernacular name. They resemble sting-rays in having barbed spines on the tail, but are characterized by their remarkable teeth, which form tessellated structures well adapted for crushing the shell-fish, etc. upon which they feed. A common southern species, *Myliobatis australis*, is yellowish in colour with large blue spots; it is often secured by trawlers, and its 'wings,' together with those of sting-rays, are sold in the markets as 'skate.' Another species, *Aetobatis narinari*, a denizen of tropical waters, is remarkable for its long whip-like tail, which may be four times as long as the body. It is dark in colour, with large white spots, and attains a width of six feet. A.R.McC.

Eagles. See HAWKS.

Eardley-Wilmot, SIR JOHN EARDLEY (1783-1847), born in London on 21 February 1783 and educated at Harrow, was called to the bar at Lincoln's Inn in 1806 and for a time practised on the Midland circuit. In 1808 he settled down on his Warwickshire estate, farming and performing the usual magisterial functions of an English landowner. In 1821 he was made a baronet in recognition of the services of his grandfather, who had been chief justice of the common pleas from 1766 to 1771. In 1822 he published an abridgement of Blackstone's Commentaries, and from 1832 to 1843 represented northern Warwickshire in parliament. During these years he wrote a good deal on prison discipline, and in 1843 Lord Stanley, then colonial secretary under Sir Robert Peel, offered him the governorship of Tasmania, where it was proposed to institute a new system of penal reform for which see CONVICTS. On 21 August 1843 Eardley-Wilmot took office as lieutenant-governor of Tasmania, the first civilian to occupy that position; in 1844 his authority was extended to include the administration of Norfolk Island.

He was confronted from the outset by very great difficulties. Thousands of convicts were being poured into the colony during a period of financial depression, when industry was at a standstill. By the beginning of 1847 the population numbered 66,000, of whom 29,000 were convicts. The labour of convicts employed on public works was valued by the British government at 6d. per head per day, the amount being charged against the colonial revenue, which also had to meet a large part of the cost of maintenance and gaols. The free settlers, already suffering from the economic depression, insisted that the only solution of the problem was a reduction in the number of convicts transported, and an increase in the British grant to meet indirect expenses of the penal system; but no financial relief was granted, and the country became involved in an accumulating debt. Eardley-Wilmot, after suggesting several expedients which were ignored or rejected either by the colonial office or the settlers, summoned the legislative council on 21 October 1845 to consider an appropriation bill which provided *inter alia* for an increase in *ad valorem* duties from 5 to 15 per cent. The bill was strenuously opposed by the six unofficial nominees; when the governor showed his determination to force it through, they left the council in a body, thus reducing the number of members present below a legal quorum. In explaining the reasons for their subsequent resignation they declared that they had been asked to 'vote an expenditure the colony could not bear and anticipate a revenue higher than the customs department calculated on receiving.'

This action of the 'patriotic six' was stigmatized as disloyal by Eardley-Wilmot, who maintained that they had exceeded their constitutional rights as nominees and assumed those properly belonging to elected representatives of the people—a distinction which was not supported by the colonial office. The deadlock continued until Britain agreed to contribute £24,000 per annum towards the maintenance of police and gaols; meanwhile Eardley-Wilmot was recalled, and Charles Latrobe (q.v.) appointed on 13 October 1846 to take over the administration of the colony. The recall was alleged by the colonial office to be due not to any political or economic action taken by him—though his accusations of disloyalty against the 'patriotic six' were considered extreme—but to his failure to give due attention to 'the pressing

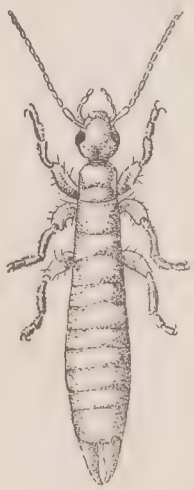
exigencies of convict discipline.' His chief task should have been to impress a 'moral and reformatory character' upon the convict system, and in this the office considered that he had failed. In a private letter Eardley-Wilmot was further informed that he would not be offered another official position, on account of rumours derogatory to his private character which had reached the colonial office. These vague accusations were indignantly repelled not only by Eardley-Wilmot himself but by the chief justice and other leading citizens of the colony, but it is probable that they were never seriously urged. It was the advent of the Whig ministry under Russell, committed to new theories of colonization and bitterly opposed to Stanley (whom they regarded as a renegade Whig), that ensured Eardley-Wilmot's dismissal on almost any excuse. Hoping, however, that justice would be done him when refutation of the attacks on his private character reached England, he remained in Tasmania, and died there on 3 February 1847.

Earthworms, members of the sub-class Oligochaeta of the division Chaetopoda (bristle-worms, q.v.), in which the bristles are comparatively few. The typical European genus is *Lumbricus*, a form which, with its nearest allies, seems to thrive wherever it is introduced and to oust the native genera. The most ancient genera, however, seem to have originated in some now sunken area in the South Pacific, and the most primitive form now extant is the New Zealand *Notiodrilus*. W. B. Benham (*Report* of the Australasian Association for the Advancement of Science, ix. 319-343) founds on the distribution of earthworms in the southern hemisphere a strong argument for the former existence of a great southern continent.

Among species endemic in Australia those belonging to the characteristic family Cryptodrilidae deserve special notice. One of them, *Megascolides australis*, found in Gippsland, attains a length of six feet with a diameter of about three-quarters of an inch. This extraordinary worm lives in burrows near the surface of the ground, and travels in them very rapidly when disturbed. Unlike perichaetous worms, which move by means of their setae, the Gippsland worm has a method entirely its own. It expands its hinder end (i.e. whichever end is hindmost at the moment) so as to wedge it tightly in the burrow, then stretches to full length, anchors its forward end by a similar expansion, loosens the hinder end, and contracts the rest of the body; the hinder end is now wedged in its new position, the body stretched again, and so on. These movements are accompanied by a distinctly audible sound—a sort of gurgle—due to the fact that the worm is slipping through a fluid secretion with which the burrow is partially filled.

Other large and notable species are *M. grandis* and *Didymogaster sylvaticus* of New South Wales. Otherwise the Australian earthworms (so far as they have yet been examined, for the western genera have not been dealt with systematically) do not greatly differ from those of other regions. It is, however, notable that they have considerable affinity with the forms found in Ceylon, and very little with those of New Zealand. T.S.

Earwigs, insects of the family Forficulidae, belonging to the sub-order Dermaptera of the order Orthoptera. They may be recognized at once by their long, slender shape, their forceps-like terminal cerci, and the high specialization of their wings. The tegmina are reduced to flaps, serving to cover the exceedingly beautiful hind-wings, which consist of an elaborately constructed fan formed from the anal area, and capable of being folded up (both lengthwise and crosswise) in a complicated manner. Only about 30 Australian species have been described, so that they do not form a very noticeable part of our fauna. Perhaps the most striking forms are the wingless species of the genus *Anisolabis* and its allies, of which the large *Titanolabis colossea* reaches a length of 2½ inches. Only the introduced species (*Forficula auricularia*) has become a pest—especially in Tasmania, where it is omnivorous; it devours plants (delighting especially in seedlings and the buds of carnations, dahlias, and chrysanthemums) the paste in the bindings of books, bread, jam, and even other insects, including the earlier stages of the codlin moth. It is also a fruit and vegetable pest, making holes in ripening apples, pears, peaches, and other stone-fruit, and destroying young potato-plants and beans. The forceps of the earwig, though capable of inflicting a painful nip, are not poisonous. One of their uses is to fold the wings after flight. The creamy-white eggs are elliptic, and are laid in clusters of a dozen or more, the mother watching over them and the young, when hatched, like a hen over her chickens. See ORTHOPTERA. R.J.T.



Titanolabis colossea.

Ebden, CHARLES HOTSON (1811-1867), son of J. B. Ebden, a politician of the Cape Colony, was born in London in 1811, and about 1832 migrated via Tasmania to New South Wales, where he commenced pastoralist. In 1835 he took up Bonegilla, the first run formed south of the Murray, and in 1837 sent overland to the Goulburn River the first mob of sheep that ever crossed the Murray; he was also active in procuring the opening of the road from the Murray to Melbourne, and bought land at the first Melbourne land-sale. When the Port Phillip district obtained representation on the New South Wales legislature in 1843, Ebden headed the poll, but resigned next year on the ground that the representation was a sham, and that a new colony should be created; in 1847 he refused re-election but returned to the New South Wales council in 1850 and took an active part in the arrangements preparatory to the separation of Victoria. After separation he became auditor-general of the new colony, but resigned after a year's service, visited England, and on his return in 1856 was elected to the legislative council. He was treasurer in the Haines-McCulloch ministry of 1857-8, and became chairman of the St. Kilda and Brighton railway; but in 1860 he returned to England, and lived there for six years, dying at Melbourne while on a visit to Australia on 28 October 1867.

Ebenaceae, a small tropical or subtropical family of trees or shrubs; 2 genera and 15 species are indigenous to Australia. The leaves are entire; flowers unisexual, the sexes on distinct plants; fruit a berry. *Cargillea* is a genus of 3 species endemic in the eastern States; *C. australis* (Black Plum, the 'boor-eera' of the aborigines) is a small tree with dark purple fruits as large as a plum, eaten by the natives. Its wood is tough, and makes excellent whip-handles. The timber of *C. pentamera* is used for flooring-boards. Of the tropical genus *Maba* 9 species are indigenous to Australia. *M. laurina* has a green, palm-like, edible fruit; *M. fasciculosa* has a strong, elastic wood, of a light colour with black streaks, suitable for carving. The timber of *M. geminata* is hard and heavy, bright near the bark, and black towards the centre; this portion is regarded as a good substitute for ebony.

Echidna, vernacular name of *Tachyglossus aculeatus,* also called 'native hedgehog,' 'native porcupine,' and 'spiny anteater,' one of the three known representatives of the sub-class Monotremata, the most primitive mammals on earth. The physical characteristics which it shares with the platypus are discussed under MONOTREMATA. The head and trunk of the echidna are together about 18 inches long, but the tail is a mere vestige. The back and sides are covered with strong pointed spines, yellowish in colour, with black tips; these are greatly developed hairs, and between them there is a covering of coarse black or brown hairs, like those which form the sole covering of the lower surface. The narrow black snout is almost cylindrical, and the mouth very small. The short and powerful limbs are specially modified to act as digging organs, and the five toes of each, which are not united by a web, are armed with very strong claws. The male, like the male platypus, has a spur—represented in the female by a mere rudiment— on the inner side of the hind foot.

The echidna does not construct elaborate burrows like those of the platypus. During the day it usually hides in crevices about the roots of trees, or among rocks, or in shallow holes which it digs for itself. At night it sallies forth in search of its food—insects of various kinds, grubs, and worms, but mainly ants and termites. These, which form the bulk of its food, it captures by means of its long, narrow and protrusible tongue, which is coated with a viscid saliva. Very rarely is the echidna encountered, even by day. When disturbed, it quickly burrows directly downwards, sinking with remarkable rapidity below the surface, even in hard soil.

In the breeding-season (winter or early spring) the female usually produces a single egg, which is deposited in a temporary pouch, formed for its reception on the lower surface of the mother's body, in an area which encloses the openings of the ducts of the milk-glands. There the young animal, escaped from the shell, and nourished by the secretion of the milk-glands—which it licks from the concave surface on which the ducts open—grows to a considerable size (about six inches in length) before it permanently leaves the pouch. When it reaches a certain size, it is no longer carried about by the mother on her nightly excursions for food.

Three varieties of *T. aculeatus* have been described. The name 'var. *typicus*' has been proposed to distinguish the common form occurring in continental Australia; var. *lawesii,* which inhabits south-eastern New Guinea, is rather smaller and has shorter spines. *T. aculeatus* var. *setosus,* the Tasmanian form, is the largest (about 20 inches in length) and has hair longer than the others. A Papuan genus *Proechidna* (with two species), is distinguished by the exceptional length of its narrow snout or beak; this is about twice as long as the rest of the head, and is bent downwards. It has usually only three claws on each foot, though specimens have been found with four and five. W.A.H.

Semon's *In the Australian Bush* (p. 162) expresses the belief that the mother echidna places her egg in the pouch by means of her long muzzle, and Wood Jones, in *Mammals of South Australia,* accepts this view. From personal observation the hypothesis appears unnecessary and probably incorrect. In three cases the present writer has found fresh excreta in the fully developed pouches of adult females; this suggests that the egg may be similarly deposited directly in the pouch, without the assistance of either limbs or snout. After transmission the pouched egg is carried about by the mother until the fetus uses its projecting snout to burst through the soft, capsule-like eggshell. Although development of the embryo is comparatively rapid, it is questionable whether it requires mother's milk for some considerable period after hatching; its relative the young platypus (q.v.) does not. But a pouched echidna, measuring 2¾ inches from tip of snout to tip of tail, convinced me by the occasional protrusion and wriggling of its long narrow tongue, combined with the continuous motion of its well-developed fore-paws, that it had become expert in the art of inducing milk to flow from the mother's teatless glands.

The young echidna is sometimes carried in the pouch until the tiny quills become troublesome to the mother; at that stage the youngster is planted in a small burrow, excavated by the parent, until it can fend for itself. Some naturalists surmise (usually on the evidence of aborigines) that the mother occasionally visits her imprisoned offspring to supply it with food. But theories based on aboriginal information can hardly be accepted as final. C. H. H. Jerrard, of Blackdown near Gayndah in Queensland, rescued a young echidna nine inches long, that had just been unearthed from a burrow by a goanna; the podgy, flabby youngster was naked, save for a sparse crop of stubbly black hairs and (here and there) rudimentary quills measuring ⅛ inch in length. At first, attempts to feed it met with very limited success, but by holding its snout forcibly in a saucer of milk it could be sometimes induced to protrude its long, slender tongue and lap a little; one such meal sufficed it for several days. After a month it would crawl a few inches to the saucer of bread and milk that always stood in its box, and help itself. It lost weight, and the only growth observable was in the length and number of its spine-points. After 10 weeks it began to nuzzle round in search of food. This and other observations suggest that the young echidna's term in its lonely burrow is a kind of hibernation, and that there is no necessity whatever for the mother to return to her offspring after depositing it therein.

H.B.

Echinodermata, invertebrate animals of which starfish, brittle-stars, sea-urchins, sea-

lilies and bêche-de-mer or trepang are familiar examples. The name, meaning 'spiny-skinned,' does not literally suit all the forms; but all have an underlying skeleton of calcareous plates (ossicles) which in most cases push the skin outwards, thus giving it a spiny appearance. Echinoderms, except one sea-cucumber which occurs in brackish water in the tropics, are marine animals. Starfish and sea-urchins are common objects in rock pools; the corona of the sea-urchin, left as such by the loss of the spines after death, is often found on beaches, and is popularly known as a sea-egg. Brittle-stars and sea-lilies live below low-water mark, and bêche-de-mer is found among the coral reefs of northern Australia. The echinoderm organization is characterized by a radial symmetry, in which the vital organs of the body are repeated, and are arranged like the spokes of a wheel round a central axis. The water vascular system is in the form of a ring surrounding the mouth. From it a number of canals (usually eight) radiate to different parts of the body; each canal bears a double series of lateral branches which push the skin out in little projections known as tube-feet; and these, besides assisting in locomotion, have a respiratory and sensory function. A stone canal is also given off from the ring; this is vertical, and communicates with the exterior by a sieve-like plate (madreporite), which is more or less conspicuous in the starfish and sea-egg. All these canals are lined with cilia, which by constant vibration produce a strong inward current that keeps the water vascular system tensely filled with water.

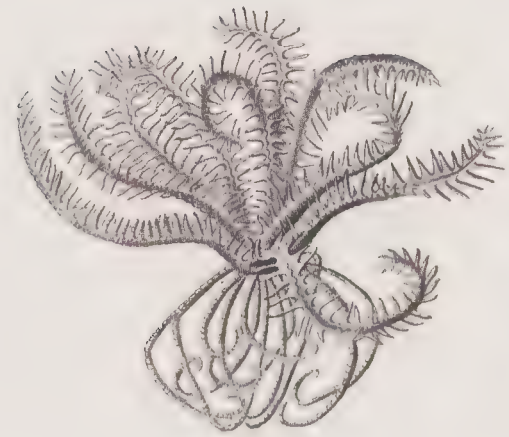
Echinoderms fall naturally into two sub-phyla, one (Eleutherozoa) comprising the freely moving members, such as the starfish and sea-urchin, the second (Pelmatozoa) including the sea-lilies and allied forms capable of becoming fixed or anchored. Of Eleutherozoa there are four classes, Asteroidea (starfish), Ophiuroidea (brittle-stars), Echinoidea (sea-urchins, heart- and cake-urchins) and Holothuroidea (sea-cucumbers, bêche-de-mer). The known echinoderm fauna of Australia includes about 670 valid species, of which 320 belong to the Holothuroidea. Two hundred species are endemic, and 65 are found only on the eastern coast.

The body of a starfish is represented by five or more arms radiating from a central disk; the living animal is usually conspicuous through its varied and beautiful colouring. The upper surface is rough or prickly; in the centre is the small anal opening, and close to it the madreporite. The spines continue down the arms, and among them a lens will reveal the pedicellariae—little stalked pincers that assist in locomotion and adhesion. The lower surface has in its centre the mouth, from which a groove runs along the centre of each arm; this is known as the ambulacral groove, and along its edges the tube-feet are constantly moving and feeling for some object to which the sucker-like tips may cling. The tube-feet allow the starfish to move in a leisurely manner, and, aided by the pedicellariae, to right itself when thrown off its balance. Having no head, the animal moves in any desired direction by the movement of the tube-feet in parallel planes; its sense of direction is probably guided by the primitive eye placed at the tip of each arm.

Like some other members of the phylum, the starfish possesses the curious powers of self-mutilation and of regenerating lost parts. It will promptly discard an arm if attacked, and eventually grow another; this accounts for the finding of starfish with one or more arms in disproportion to the others. Its food consists almost entirely of bivalved molluscs, whose shell is gripped by the closing of the arms, and the valves forced apart with the assistance of the tube-feet; the stomach is everted through the mouth, closing over the mollusc and retaining it until the food is assimilated. *Asterina calcar*, a common starfish in and near Port Jackson, has a cake-shaped body and eight short, blunt arms; the disk is mottled with various shades of black, chocolate, orange, green and purple. *A. exigua* with five rays, and *A. gunnii* with six, are equally common. Contrasted with these we have *Coscinasterias calamaria*, brightly coloured in patches of sepia and sage-green with a margin of vivid red; its long, finger-shaped arms are usually irregular in shape and size.

Brittle-stars are so called because of their habit of throwing off their arms when molested. The disk of a brittle-star is more or less circular, and the arms are not a continuation of it, but are inserted into grooves on the underside, coalescing with the frame-work that surrounds the mouth. The ambulacral grooves are represented by closed canals, and the functions of the tube-feet are purely respiratory and sensory. The arms are made up of a series of disk-like ossicles or vertebrae, each vertebra connecting with its neighbours by cup-and-ball joints. The vertebrae are also connected by powerful longitudinal muscles which enable the arms to wriggle and lash if active motion is required, or by curling to hold strongly on to weed or rocks. Brittle-stars are commonly found on the coast, tangled among weed or under stones; like starfish, they are often quaintly and conspicuously coloured. *Ophiothrix fumaria*, a pretty brittle-star found in Port Jackson and along the coast, has conspicuously banded arms. It lives under stones in the shallow water; if the stone is lifted, the timid creature promptly throws off all its arms even before it is actually molested.

Sea-urchins seem at first sight to be widely separated from the two preceding classes, but the plan on which they are constructed agrees in essence with that of the starfish and the brittle-star. The corona of the sea-urchin consists of ten bands of plates, each differing from its nearest neighbours, so that five bands of ambulacral and five bands of interambulacral plates are formed. A circle of plates on the upper surface shows further differences in formation. Each row of plates is studded with bosses and tiny elevations; the larger and smaller bosses are for the attachment of the primary and secondary spines respectively, the little elevations (miliary tubercles) are for the pedicellariae. The ambulacral bands have rows of pores round their edges, through which the tube-feet protrude. The ring of plates round the upper surface consists of five larger (genital) plates and five smaller (ocular) plates, each of the latter bearing in life a rudimentary eye; a madreporite is amalgamated with one of the genital plates. The under-surface of the corona has a large opening, through which mouth and jaws may protrude. The mouth is surrounded by an external membrane, and five chisel-edged teeth together form a structure known as 'Aristotle's lantern;' this lantern is often found in the sea-egg. The whole body is covered with skin, bearing numerous pedicellariae; these, owing to the presence of the long spines, cannot subserve locomotion or adhesion,



1

5

1. Feather-star, *Amphimetra discoidea*
2. Sea-urchin, *Toxocidaris erythrogrammus*
3. Bêche-de-mer, *Holothuria colubra*
4. Starfish, *Anthenea acuta*
5. Brittle-star, *Pectinura marmorata*

and are probably used to clean the skin. Echinoids are of various shapes and sizes, as the names 'cake' and 'heart' urchin would imply. The spines of a large sea-urchin (*Heterocentrotus mammillatus*) are used as slate-pencils by children at Cooktown in Queensland. *Toxocidaris erythrogrammus*, a dark purple urchin with dense, short, fluted spines, is very common along the coast-line. It excavates for itself a deep cup-like depression in the sandstone, and leaves this retreat in search of food when the tide suits, but returns as soon as the tide changes. It is apparently nervous and, while in its cup, further protects itself from observation by holding pieces of shell and stone over its body by means of the pedicellariae; these pieces must have been gathered by the elongated tube-feet that protrude from the dorsal surface. *Amblypneustes ovum*, a pretty urchin inhabiting Port Jackson, makes its home in dwarf kelp, and uses its tube-feet to draw a leafy curtain round itself.

The species of *Holothuria* (sea-cucumbers, trepang, bêche-de-mer) have no arms or spines. The skeleton consists of little nodules of calcium carbonate embedded in the skin. A system of longitudinal muscles enables the animal to move with slow, worm-like contractions of the body; while moving, it sweeps its tentacles (which are in a mop-like tuft) over the sand and thrusts them into its mouth with the sand they have caught up. The food matter consists of foraminifera, which are swallowed along with a big percentage of sand and fragments of coral. Bêche-de-mer is of economic importance. On the Great Barrier Reef (q.v.) the creatures are collected into sacks, taken to the curing stations, and boiled in cauldrons for 20 minutes; they are then taken out, slit open and gutted, and exposed to the sun until the greater part of the moisture has evaporated, and smoked in a 'smoke-house.' Smoking takes about 24 hours, the wood most in favour being that of the red mangrove; it greatly reduces the size, so that the finished article looks very much like a charred sausage. Luggers of five to six tons burthen are used for fishing, and often carry their own smoke-house. Aborigines and Malays are largely employed in the work. The average annual value of bêche-de-mer obtained in Australia for 1919-22 was £57,875.

Sea-lilies and feather-stars belong to the Pelmatozoa. Of the five classes into which this sub-phylum is divided only one—the Crinoidea—includes living forms, and these are few in number compared to the fossil forms contained in the other four. There are 66 known species in Australian waters, excluding those that live at depths of over 300 fathoms. From the main part of the body (calyx) long delicate arms radiate, each bearing a series of shorter branches (pinnules). The calyx is in most cases built up of several whorls of plates; the anatomy in the main corresponds with that of the Eleutherozoa. Pelmatozoa are fixed or anchored (at least in the younger stages) by the centre of the ab-oral surface; this is produced into a stem covered with small outgrowths (cirri) by means of which the animal anchors itself. Many forms have become free, and swim with graceful movements by muscular contractions of the arms. Sea-lilies grow in fields in deep water; the decks of cable-repairing ships are often strewn with them after a cable has been lifted from the ocean bed.

R.W.B.

Education, Public. Throughout Australia education is made a matter of the first public concern. Primary (elementary) education is everywhere compulsory and, partly as a consequence, partly from enlightened policy, is everywhere free to those who receive their teaching in the state schools. Meanwhile, subject to precautions which will be stated later, both private tuition and attendance at non-state schools are accepted as substitutes. Each State regulates its own system, makes its own appointments, and provides for the necessary expenditure. That this is fairly liberal may be judged from the fact that in New South Wales, the State with the largest population, the expenditure upon all forms of educational and scientific activity for 1922-3 amounted to £3,777,551. Though the several systems are thus independent, they are nevertheless brought into a general harmony by reciprocal comparisons and consultations as to both aims and standards, and—as will be seen—differ only in details, which are mainly determined by differences in the resources or other special conditions of the respective States. In the Federal Capital Territory it has for the present been found geographically convenient to place primary education under the system and conduct of New South Wales, the Commonwealth bearing the expense; in the Northern Territory the Commonwealth itself administers; but in both areas the children of school age are still but few. The results of this attention to educational progress are apparent from statistics. The illiterates among Australian-born people between 60 and 64 years old number almost 4 per cent; for those between 40 and 44 the figures are under 1¼ per cent, and for those between 10 and 15 just 6 per thousand. In metropolitan areas the number between 10 and 15 is only 4 per thousand, and outside them illiteracy among the young increases with the sparseness of the population.

This article deals only with primary and secondary schools under government control. For university education see UNIVERSITIES; for the history of private education see SCHOOLS.

Primary Education.—The early history of primary education is necessarily that of its development in *New South Wales*, which once included all the eastern colonies of Australia. There education for several decades followed the usual course, beginning with voluntary enterprise supported in some measure by various religious denominations, gradually gaining more and more recognition and financial aid from the government, and ultimately passing either entirely into its hands or under its more or less strict supervision. Naturally, a struggle of vital importance was long maintained over the questions whether religious instruction should be included in the curriculum, and whether, if particular denominations established their own schools, they should receive supporting grants from the State. Nor are those questions yet dead, although under the existing systems they might appear to have been definitely answered.

No schoolmaster arrived with the 'first fleet' in 1788, and the first modest endowment of education began in 1794 with a grant to Richard Johnson and William Richardson of £10 per annum from the Society for the Propagation of the Gospel. That payment was continued by the society to a number of schoolmasters until 1830, though meanwhile more substantial and systematized aid had become available. Thus in 1802, before any 'school rate' was thought of

in England, settlers about the Green Hills (i.e., in the Windsor district) had agreed to pay 2d. per acre for 14 years to maintain a school in their district. In 1807 Samuel Marsden (q.v.) being in England, aroused the colonial office to the need of education in New South Wales, and under Governor Macquarie schools were established in the principal centres. After 1810 they were generally established by grants from the administration, derived from certain customs duties earmarked as 'orphan dues' (so named from their original application to the upbringing of orphans). During all the early period religious instruction, including the Anglican catechism, was given everywhere without regard to the denomination of the pupils, but in 1836 Governor Bourke advised that the 'Irish National System' should be introduced into the colony. This arrangement, though approved by the authorities in London, was strenuously opposed in the colony, and nothing was done until 1841, when regulations issued on 24 September made provision for government grants-in-aid to all schools—irrespective of denomination—on a scale determined by the number of children of poor parents enrolled. It would appear that in many schools a practice had grown up, and had become notorious in 1840-1, of charging to government account half the cost of educating children whose parents could well afford to pay their fees. In 1844 Robert Lowe (afterwards Lord Sherbrooke, q.v.) carried in the legislative council of New South Wales a motion for a select committee to report upon education as suited to the needs and wishes of the majority of the community. The report (which revealed the fact that half the children between 4 and 14 years of age were receiving no education at all) favoured a general system in preference to a denominational, and recommended that adherence to such a system should be a condition for receiving government aid. The scheme would institute a board invested with wide discretion, its leading principle being that the same facilities should be afforded to all Christians without attempt to interfere with any denomination or to proselytize. Supporters of denominational education were, however, strong enough to maintain the *status quo* until 1848, when an awkward system of dual control came into being. A board of national education was established side by side with a board of denominational education—the latter being composed of the representatives of the Anglican, Roman Catholic, Presbyterian, and Wesleyan Churches, appointed to distribute the sums voted for the denominational schools. By 1850 there were 43 national schools, and 52 others in process of formation; the denominational schools numbered 185. The result was a vexatious rivalry between the two boards, until in 1867 Parkes's public schools act placed the public expenditure for primary education under a council of education; this was given the fullest powers, including provision for granting aid, under certain restrictions, to denominational schools. In all schools instruction was to be both secular and religious, but the term 'secular,' even in the state schools, included general (i.e. undogmatic and unpolemical) religious teaching. The feeling against the grant of financial support to denominational schools grew to such an extent that in 1880 this aid was withdrawn by the public instruction act (also fathered by Henry Parkes), which placed education under a responsible minister and made the teachers civil servants, but retained the secular-religious teaching in the same sense as before.

In *Victoria*, after its separation in 1851, two boards were created and the old dual control continued till 1862, when, by a common schools act the boards were dissolved in favour of a single board of education. This, however, failed to provide an equal distribution of facilities, and was abolished by the education act of 1872, a department of education being established under a minister. In *Queensland*, a board of general education, created in the second year (1860) of its independence, followed in the main the Irish national system. Besides the 'vested' unsectarian schools of the colony, 'unvested' schools, Anglican or Roman Catholic, were aided by grants. In 1875 the state education act abolished the board, and its powers were transferred to a department of public instruction under a minister. State aid was withdrawn from denominational schools in 1880. In *Tasmania* the first Anglican clergyman, Robert Knopwood, aided the Methodist immigrants of 1818 to establish schools. By 1828 there were 8 government schools, and by 1836 there were 29. Originally schools were established in connection with religious bodies, and assisted by state grants; in 1846 the system was to pay to denominational schools 1d. per day per head of pupils attending. By the education act of 1885 primary education passed to a special department under a minister. In *South Australia* the first school was established in 1836 on Kangaroo Island, where Captain Bromley taught the children 'under a large and beautiful tree' and subsequently in a hut. Up to 1875 the educational activities of the State were mainly confined to subsidizing private institutions, but in that year was appointed a council of education to provide state schools and compel attendance thereat. In 1878 its powers were vested in a minister of education. In *Western Australia* an elementary education act of 1871 provided for a central board of education controlling government schools; other schools were assisted by grants. The board was dissolved by an amending act in 1893, and its place was taken by a ministerial department of education. In 1895 assistance to non-state schools was abolished.

At the present date (1925) each State possesses a permanent head of the public educational system, known as 'director of education' (in Queensland as 'under-secretary'), whose business it is to control the whole service so far as it falls under the several education acts. In both Victoria and South Australia there also exists an advisory council of education, which offers reports and recommendations upon methods and developments and upon the co-ordination of the educational activities of their States.

In all parts of the Commonwealth there are to be found (*a*) primary 'state' schools (officially known in New South Wales and South Australia as 'public' schools), staffed by duly trained and qualified teachers working with a prescribed syllabus and under regular examination by inspectors, and (*b*) non-state schools of various descriptions, some denominational, some private. Domestic tuition is also permitted. The only point upon which all the States insist is that a proper education shall be given to each child, so far as it is possible to achieve that end—though, in view of geographical and other conditions, a certain elasticity is rendered inevitable in the matter of enforced attendance.

The compulsory school age-limits are 6 to 14

(in New South Wales and Tasmania 7-14), exemption being granted to pupils over 13 who have reached a qualifying standard. In some schools the lowest, or infant, classes are taught by modern kindergarten methods, but before reaching school age children are commonly dealt with by free kindergarten unions working on Froebelian or Montessori lines, the State assisting in the training of the teachers. Legally attendance at school is required on every occasion on which the school opens, unless sufficient cause be shown for absence. Excuses accepted as valid are (1) regular and efficient instruction elsewhere, (2) physical or mental disability, (3) excessive distance from a school, (4) such other pleas for non-attendance as may seem reasonable to the authorities. The distance considered excessive depends somewhat upon the age of the pupil, and is calculated by the nearest available route. Thus in South Australia it is 1 mile of walking distance for pupils between 6 and 7 years of age, 2 miles between 7 and 9, 3 miles between 9 and 14. The same rule applies in Victoria, except that 2½ miles are allowed between 9 and 11. In New South Wales it is 2 miles up to the age of 11, then 3 miles; in Western Australia the compulsory radius is 2 miles for children under 9, but 3 miles after that age. In Queensland the maximum is 3 miles. Every precaution is taken for ensuring regularity. Thus in Victoria 'no person shall within school hours employ or permit to be employed any child not legally exempt,' nor can any child be so employed before school hours if the profitable use of school time is likely to be endangered. In South Australia the penalty for the breach of a similar provision is a fine, maximum £5. Truancy, or allowance of truancy, is punishable by fine or imprisonment of the parent or other person on whom the onus rests. Head teachers are required to supply to their departments a full account of attendances, causes of absence, and statements of special circumstances. 'Efficient attendance elsewhere' has reference to non-state schools and domestic tuition. The terms on which these are accepted vary somewhat in the different States, but their general effect is the same; the department must be satisfied. Thus in South Australia the principals of private schools are required to keep rolls of attendance for pupils of compulsory age and to supply the same information as is demanded of the state schools. In Victoria 190 working days in the year are required of the private institutions. In Tasmania private tuition is accepted if the inspector of schools reports that the child is being properly educated. In New South Wales the proprietor or head teacher of any non-state school must prove to the satisfaction of an inspector of schools that regular, as well as efficient, instruction is being given and non-state schools must be 'certified;' otherwise they are not regarded as schools within the meaning of the act.

In respect of registration and supervision of non-state schools there is no uniformity among the several States. In Victoria private schools can only be established with the authorization of the registration board of the council of public education, which calls for proof of the qualifications and adequacy of the staff and the suitability of the buildings. In New South Wales there is no registration act for teachers, although principals may apply to have their schools placed on a registered list. Such schools may be inspected by the direction of the minister from time to time, and their certificates may be cancelled; an inspector or medical officer may enter to examine drainage, light, ventilation, etc. In Tasmania private schools are controlled by the teachers' registration board, which can approve or disapprove of their registration as schools. In South Australia inspection of a private school is made only on the request of the proprietor or principal. Except in Victoria and Tasmania the relations between state and non-state primary education, and the qualifications and classification of non-state teachers, seem badly, if at all, systematized. In the two States named every school is registered as 'sub-primary,' 'primary' or 'secondary,' or as any two or all of these. The registration board determines the right to any of these titles, and no person can conduct any school or teach in it unless it has been registered. It is presumable that in course of time the various systems will be brought more into line with each other.

In 1923 the numbers of pupils attending state primary schools were—South Australia 90,500; Queensland 129,139; Tasmania 31,552; Victoria 216,329; New South Wales (1922) 320,398. (The number for Western Australia is not forthcoming.) When compared with the total number of children of compulsory school age, these attendances amount to an average of over 80 per cent; the non-state schools and private tuition account for the remainder.

Primary education being compulsory, it has also been made free for the compulsory age. Though in the earlier days fees were exacted, the several States have sooner or later arrived at this common principle. The total abolition of fees dates in Victoria from 1873, in Queensland from 1875, in South Australia from 1891, in Western Australia from 1899, in New South Wales from 1906, and in Tasmania from 1908.

That the education publicly provided should be secular was an early resolve of most of the colonies. This decision arose from no hostility to religion, but from a due recognition of the claims of the various denominations and the necessity of avoiding conflicts. Nor does the system in practice prevent a proper teaching of religion. 'Secular' is mostly to be taken in the sense of undenominational and undogmatic, rather than of non-religious. So far as 'religious' teaching proper is concerned, attendance of the pupil is optional, and the several sects commonly make their own provision. But here again the States are not entirely of one mind. Thus in Queensland it was decided in 1910, as the result of a referendum poll, that teachers must include in their programmes the reading of Bible lessons selected from a special compilation of the department. While they are themselves debarred from inculcating the tenets of any particular denomination, instruction in that kind may be given by a clergyman in school-time for one hour per week to the children of his sect whose parents or guardians may wish them to attend. On the other hand, in Victoria no state teacher may give any instruction other than secular in any state-school building; but other persons may, by order of the minister, give religious instruction in the schools for half an hour on one or two days in the week, the attendance at such times depending on the wish of the parent or guardian expressed in writing. Full advantage of this provision is taken by the clergy and others under an elaborate organization of the council of the churches. In New South Wales denominational representatives have up to an hour of school time weekly at their disposal, and the 'secular' instruction of

the ordinary staff includes 'general' religious teaching. In South Australia no denominational religious teaching is allowed in any public school, but any primary school may open in the morning, before the time fixed for secular instruction, for the purpose of reading portions of the Bible in the authorized, revised, or Douay versions. In Tasmania the regular staff is required to give in school hours instruction in 'scripture history and morals,' such teaching being entirely non-sectarian and intended to 'inculcate an attitude of reverence and to create an interest in matters of spiritual suggestion.' Whether a child shall attend at 'sacred history' is optional with the parent; for the first or last half-hour in each day a clergyman may instruct the pupils of his own denomination. Though all this is so much compromise, there is no State which does not in some way attempt moral teaching, whether by Biblical lessons and narrative or by means of inspiring stories from history or some suitable reading matter.

The curriculum of the primary schools throughout the Commonwealth may fairly be described as liberal and 'up-to-date.' The subjects commonly included are reading, writing, grammar, and expression in English; arithmetic (written and mental), practical geometrical work, mensuration, and simple algebra; morals and civics; British and Australian history; geography; nature knowledge and elementary science; drawing and brushwork; manual work in simple crafts and modelling; singing; needlework for girls; drill for boys, and physical exercises for both sexes. At the close of a satisfactory primary course the pupil receives a 'qualifying certificate.' As it is a regular principle that every boy or girl should, as far as possible, find access to higher education up to and including the university, the path is made easy to industry and talent by the provision of numerous exhibitions and scholarships at each stage.

The geographical conditions of Australia being what they are, and the diffusion of its population being so wide and in many quarters so sparse, it has been a difficult matter to meet the educational needs of every family. Yet every reasonable endeavour has been made. When a school, though distant, is reachable by some sort of conveyance—train, horse-vehicle, or motor-vehicle—the States have for the most part met the expense, leaving to the parents the responsibility for the necessary arrangements. In New South Wales children are conveyed, when it is fairly practicable, to some 'central' school, free transport being provided on the state railways to the nearest, or concession rates being granted to those more remote. In Victoria an allowance of 3d. or 4d. per day is made for the transport of children to the nearest school, if it lies at a greater distance than those specified for a walking route. A similar arrangement exists in South Australia. Queensland permits children at an inconvenient distance from a school to travel free by train wherever there is railway communication. Tasmania allows up to 6d. per day for conveyance from a distance of 4 miles or more, or stationmasters may issue free passes to the nearest school. Nor is there any undue parsimony in the supply of schools in thinly populated districts. Thus in South Australia the department establishes one wherever an average of 6 pupils can be maintained. In New South Wales 'provisional' schools may be established where there are more than 10 in attendance, and 'half-time' schools where a smaller number can be collected. Victoria also provides full-time or half-time schools for groups of at least 10. In addition both New South Wales and Victoria subsidize, to the extent of £70 and £50 respectively, schools in which an approved teacher has been selected by parents in an out-of-the-way district. Meanwhile in Queensland, New South Wales, and Victoria 'itinerant' teachers proceed by car, cycle, etc., to deal with small groups or families in turn imparting instruction, advising, and leaving directions for work. The 'travelling' schools of New South Wales are vans equipped with all necessary school material, and move from family to family, returning in a regular circuit. In 1923 the Queensland government decided to build and equip two railway cars each 43 feet long, for teaching girls in out-back regions such subjects as cookery, house-wifery, laundry work and needlework. Each car remains at a stopping place from six to eight weeks. Girls over 12 years receive instruction for not less than four days in the week; in the more sparsely populated districts girls under 17 who have left school are also taught. Each week one day is given to a demonstration for adults. During 1924 the two cars visited 14 centres. Finally 'correspondence' schools in the capitals deal with isolated cases in the country, the education being mostly confined to 'the three R's' and performed by written work transmitted and corrected. As soon as the population becomes sufficiently close, schools are everywhere established. Nor are the aboriginals neglected. Thus in New South Wales the native children of school age are taught by specially trained teachers at aborigines' mission stations in various quarters.

The medical inspection of state schools, though not ungenerously treated, is in some cases said to need a larger staff. In New South Wales 8 medical officers (of whom 4 are women) examine every school child once in every 3 years; 11 travelling dental clinics deal with a conservative treatment of the teeth, and in sparsely settled districts a travelling hospital concerns itself with the eye-troubles which are frequently prevalent there. In Victoria 4 medical officers visit both the elementary and the high schools; to complete this service, arrangements are made with the public health commission for assistance from district health officers. Queensland employs local medical practitioners, who examine the pupils, make records of their physical condition, and suggest treatment; these are assisted by a staff of trained nurses; where hospitals exist the medical officer is engaged by the department to give his services without charge. Dental inspectors regularly visit the schools and perform operations gratuitously. In South Australia the scheme provides for inspection of all children twice during their school life, parents being notified of any defect likely to interfere with their progress; a dentist with a trained nurse visits the far back schools, mainly to educate the children in the care of their teeth; and lectures are given to teachers on hygiene and the prevention of disease. Tasmania employs full-time medical officers in the country and, in the towns, part-time doctors and full-time nurses.

Departmental officers administer the regulations applicable to a whole State, but the special interests of particular schools are watched by local bodies known as 'school committees' (Victoria, Queensland, South Australia), 'boards of advice' (Tasmania), or the like. These are commonly nominated or elected at a meeting of the parents and guardians concerned,

but are appointed by the minister. In New South Wales a 'public school board,' nominated by a parents' and citizens' association, may have under its care either a single school or a group. Such committees or boards have no part in the appointment of a teacher, and no power to interfere with the curriculum or methods; they are concerned only with the buildings, grounds, and minor requirements of a school and with any local complaints which may arise. They are expected to lend general support and protection to a teacher, and to assist him in securing a proper attendance of the pupils, but may also report to the minister upon cases of intemperance, gross immorality, or flagrant neglect of duty. In Tasmania they may meanwhile suspend a teacher for such causes.

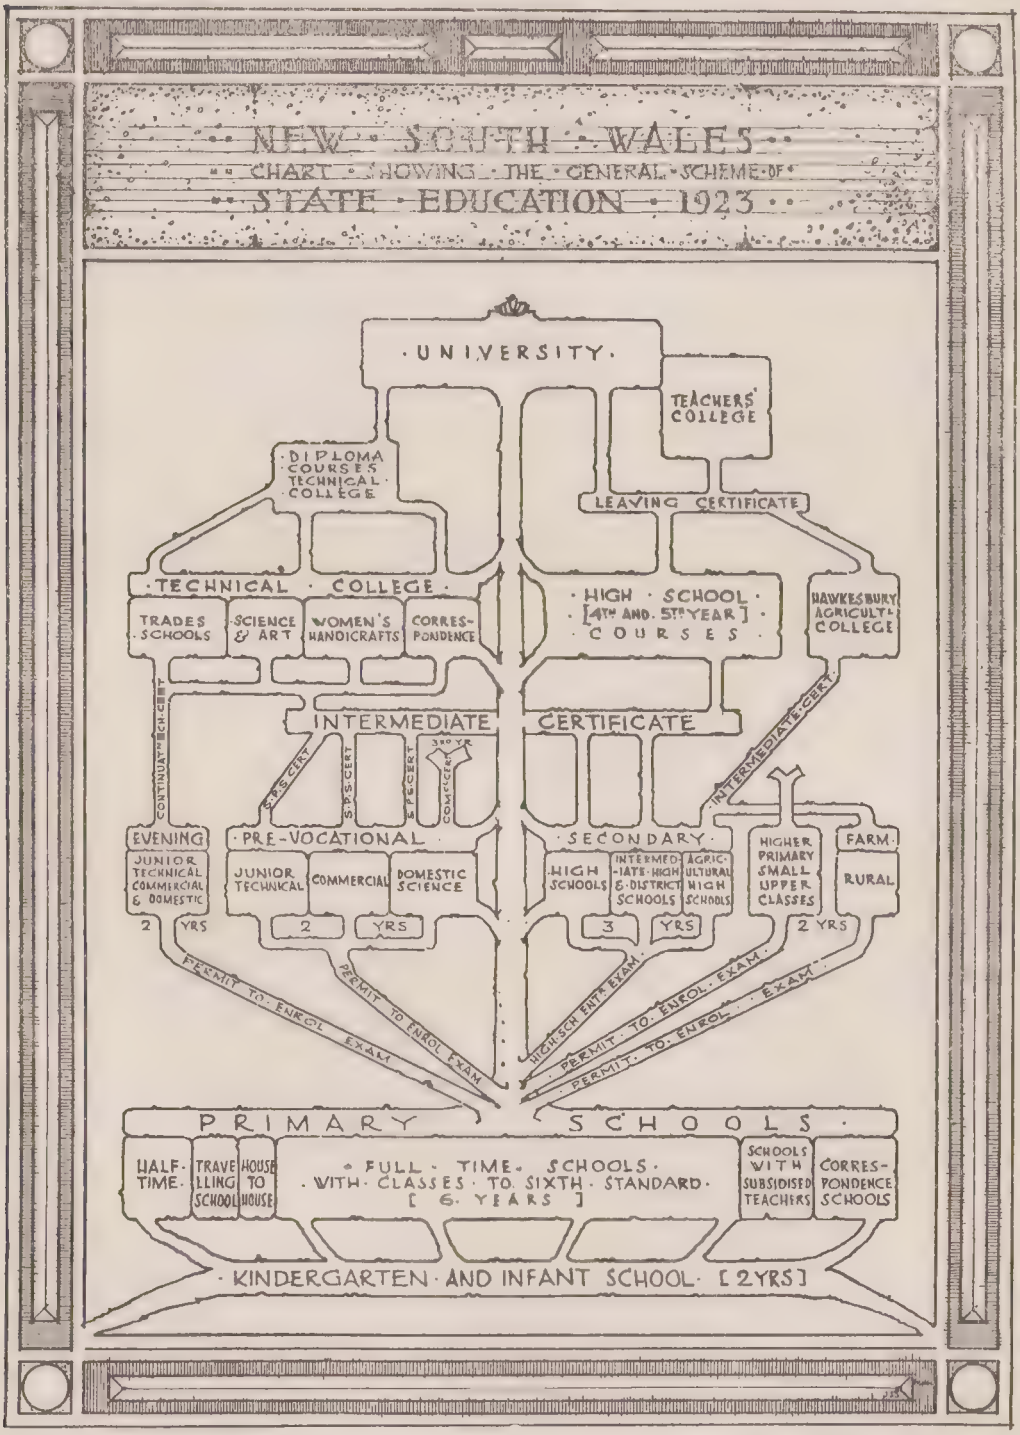
Secondary Education.—The provision of an efficient secondary education by the State is of comparatively recent growth in Australia, and even at the present day the larger proportion of such work is performed by non-state schools —styled 'grammar schools,' 'high schools,' 'colleges,' and the like—many of which are private enterprises. A considerable number are either endowed institutions controlled by councils appointed by the various denominations which founded and support them, or else schools subsidized under some body of trustees with public responsibility. Schools of the last two classes are generally classified as the 'public' secondary schools, the term implying an analogy to the great public schools of England, upon the model of which they are tending more and more to form themselves. The history of the origin and growth of these non-state schools is, for convenience' sake, given under SCHOOLS. In some cases such schools received endowments of land and building grants from governments at a date prior to the establishment of state high schools and colleges, the remainder of the necessary funds being derived from the private subscriptions of those interested. This was the case, for instance, in Victoria with the Church of England grammar schools of Melbourne and Geelong, and the Melbourne Scotch College, St. Patrick's College, and Wesley College. To such 'public' schools, though brought into the list under other circumstances, additions have been subsequently made. In New South Wales the greater schools of a 'public' type include the Sydney grammar school (undenominational, subsidized by the state, and managed by trustees), the Church of England grammar school at North Sydney, Newington College (Wesleyan), Scots College, The King's School at Parramatta, and St. Ignatius' and St. Joseph's Colleges (Roman Catholic). The Queensland system of endowed grammar schools (as at Ipswich) is mentioned below. For girls there exist everywhere non-state schools of a size and standing corresponding to those of the boys' schools, the majority being private ventures, but many denominational, with such titles as Church of England girls' grammar school, Presbyterian Ladies' College, Wesleyan Ladies' College; and there are also many Roman Catholic convent schools. Where a registration act is in full force, any non-state secondary school is brought under the same regulations with the primary schools as to graded qualifications and classification of its staff. Elsewhere the intervention of the state is of the slightest. The standard of work in Australian secondary schools is practically the same as that of similar institutions in Great Britain.

But with the growth of the communities, and the progressive conceptions of educational requirements, the state has tended increasingly to take secondary education into its own hands by the foundation of state high schools, technical schools or colleges, agricultural colleges, and similar institutions. Not only do these provide a full instruction of the grade and kind implied by their titles; they are for the most part rendered easily accessible by liberal exhibitions from the elementary schools, by very low fees where fees are charged at all, and by other allowances. State high schools exist in every State, whether as full high schools with a curriculum leading to the universities or as 'intermediate' or 'higher elementary' schools with a less extensive range. Thus the full course in South Australia, New South Wales, and Victoria is one of 5 years; the intermediate course may be of 4 years (Victoria) or 3 (New South Wales) or, in the 'higher primary' schools of South Australia, of 2. 'Intermediate' and 'leaving' certificates are issued according to the grade achieved. In general pupils gain admittance to state high schools on passing a qualifying examination from the lower schools, and are then usually of the age of 12 or 13. Numerous and substantial scholarships (160 in Victoria) or bursaries, awarded for merit in the qualifying examination, are tenable at state high schools, and in some States at other secondary institutions approved by the department. In Queensland there are also 10 subsidized grammar schools, established under an act of 1860 in districts where not less than £1000 had been privately subscribed. A condition of the subsidy is that they shall receive a certain number of winners of 'district scholarships' from state schools. Western Australia is comparatively ill-provided with state high schools, but in the larger centres the upper classes of primary schools are brought together into central schools, where special arrangements are made for higher work up to the age of about 16.

In addition to the ordinary high schools all the States possess technical schools (or colleges) for pupils proceeding to a business career or to vocations demanding some degree of craftsmanship. Thus (to take a single State) South Australia has technical high schools, junior technical schools, country technical schools, schools of arts and crafts, and apprentice trade schools. The 'rural' schools of Queensland deal with those who go on to manual arts, commercial work, or elementary agricultural science. In New South Wales technical education includes courses in 'home economics' (i.e. cookery, hygiene, dressmaking, and household accounts). Agricultural colleges or schools exist in all the States of the mainland, and in Victoria 9 district high schools have farms attached for instruction in theory and practice. In Tasmania certain high schools include an agricultural course. See AGRICULTURAL EDUCATION.

Every endeavour has been made to distribute these secondary institutions fairly in each State. Thus, to take a single typical example, Victoria has 45 higher elementary schools (44 in the country), 33 high schools (27 in the country), and 27 technical schools (14 in the country). Of the 17 technical colleges of Queensland each important town has one. Of the 23 high schools of South Australia, 19 are in the larger country centres. In the matter of fees the States differ but slightly. For the most part instruction is free, but fees are sometimes payable in more special schools or advanced grades, e.g., at the South Australian school of arts and crafts and, on a lower scale, at the country technical schools.

In Victoria low fees are paid after the age of 14 at the high schools and junior technical schools, and those at the senior technical schools depend upon the subjects taken.



The 'Educational Ladder' in New South Wales.

A liberal number of bursaries, scholarships, and exhibitions are awarded from the secondary grades to the universities. New South Wales annually awards a number of bursaries as well as 200 exhibitions, the latter entitling the holder to exemption from all fees for matriculation, tuition, and degrees. For both bursaries and exhibitions a pupil from a non-state school may

compete, provided that the school has been registered with the department as competent to give instruction up to the required standard. Victoria offers 42 'senior' school scholarships at the university, and 70 'free places.' Queensland awards for distinction in the university senior examination 20 scholarships, which carry with them free tuition and £52 per annum if the student must reside away from home, £26 otherwise. Tasmania has 5 or 6 bursaries.

The pupils attending high, technical, and agricultural schools in 1923 were—South Australia, 11,451; Queensland, 15,651; Tasmania, 1708; Victoria, 31,474; New South Wales ('secondary and super-primary'), 32,422. Figures for Western Australia are not forthcoming.

Training of Teachers.—The teachers in the state institutions are civil servants under the education departments, and are paid according to a fixed scale of classification and promotion. Entrance to the service depends upon the regulations of the several States. In New South Wales a candidate may either enter the training college, or tender satisfactory evidence of teaching experience and training in a teachers' college elsewhere. In the college he may take either a 'long course' of from 2 to 4 years or a 'short course' of a single year, those who take the latter being generally sent as assistants to country schools or to take charge of small ones. The college has 600 places, of which the majority are reserved for students who have pursued a full course in the high schools. In Victoria candidates are drawn from high and other secondary schools. In most cases they begin as junior teachers on the staffs of the larger schools, and are trained in theory and practice by the headmaster. After a year's service they may apply for admission to the teachers' training college for courses of from 1 to 4 years. Juniors not entering the college are eligible for promotion after completing the junior teacher course (usually 3 years). Under the registration act all teachers in any school, non-state included, must give evidence of ability to teach. In South Australia a teacher must enter the training college for from 1 to 4 years; a single year suffices for the less important posts in primary schools, 2 years for ordinary primary positions, 3 or 4 years for those in a high school. In Queensland young teachers are still employed (usually for 4 years) as 'pupil teachers' in primary schools, but the number of these entrants is declining. Ex-pupils of secondary schools receive preference, and undergo a shorter probation. A teacher is 'classified' after examination and satisfactory evidence of ability. Others proceed to a training college, which provides scholarships. Tasmania also has its training college. T.G.T.

Eels (family Apodes). About 50 species occur in Australian seas, being most plentiful in the coral regions of the tropics. Many are remarkable for their bizarre coloration and marking. The reef eels (*Gymnothorax*) are commonly regarded as marine snakes, and some larger species are feared by divers because of their ferocity and power to inflict severe wounds with their large and sharp teeth. Marine species live in the crevices of rocks and reefs, but the freshwater eels (*Anguilla*) are more partial to a muddy environment. Larval eels differ much in appearance from the adults, having broad, flattened, transparent bodies, with very small heads. In their development towards the adult form they decrease in size as they acquire the typical cylindrical shape. Freshwater eels breed in the sea, to which they generally migrate during periods of flood. The young congregate at the mouths of rivers, and in making their way upstream surmount many obstacles that would appear sufficient to bar their progress. They even leave the water and cross land, moving in wet grass in order to migrate from one stream to another. A.R.McC.

Eight-hour System. The first mention of an eight hours' working day in Australasia was made in 1847, in the articles of association for the settlement of Otago in New Zealand; but the clause guaranteeing this time-limit was withdrawn, though the agreement was tacitly kept. Towards the close of 1848 surveyors and their parties in the employ of the Otago Association were called upon to work nine and ten hours, but the settlers resisted. A mass meeting was summoned by a settler, S. Shaw, and it was unanimously agreed that the men should work for eight hours only; the trouble was ended by the opportune arrival of an English settler, Valpey, who immediately announced his intention of absorbing all available labour and maintaining an eight hours' working day.

In New South Wales in 1855 there were in existence a few trades organizations, one of which was the Operative Stonemasons' Society. At a meeting of this society, held in the Parramatta Hotel on 22 September 1855, a certain Hugh Laundry proposed 'That in the opinion of this Society eight hours should be the maximum of a day's labour.' This was carried unanimously, and almost all Sydney contractors at once conceded the boon. Messrs. Tooth Brothers, however, who were then building their Parramatta-street brewery, objected; the society at once withdrew its members (the greater number of whom were immediately absorbed by the contractor for the Parramatta waterworks), and in less than a fortnight all opposition was withdrawn.

The operative stonemasons of Melbourne moved in the matter early in 1856, and after several trade meetings and a conference with employers, decided at a monster meeting at the Queen's Theatre on 26 March that the system should come into force on the following 21st of April. The first procession was held on 21 April (a date since commemorated annually). In 1857 nine trades and about 700 men took part in the procession: the eight-hour system was rapidly extended, and in 1870 the government made it the official working day in government contracts. The factory act of 1873 ordained that no woman or girl should work for more than eight hours a day, and in 1877 the limitation was extended to all employed underground in mines.

Queensland followed the Victorian example, and celebrated the inaugural eight-hour festival in 1866, the pioneer trade again being the stonemasons. The first Sydney festival was held in 1871 by four eight-hour trades—bricklayers, stonemasons, labourers, and carpenters. In South Australia the establishment of the system was accomplished in 1873, the building trades (stone-cutters, painters and carpenters) being the leaders. In New Zealand the first trades congress was held in 1885, and in the same year there was a general celebration of the eight-hour principle by the combined trades. Trade

unions were first established in Tasmania in 1874, the shipwrights of Hobart being the pioneer society, and an eight hours' day one of the chief aims: as in Sydney, it was conceded after a strike. The inaugural celebration took place in 1890, the 26th of February being the day set aside. In Western Australia unions were formed soon after the discovery of gold, and 'eight hours' was established as the work-limit in 1896.

See Murphy's *History of the Eight Hours Movement* (1896); Spence's *Australia's Awakening* (1909); and the same author's *History of the Australian Workers' Union* (1911).

Elaeagnaceae, a small family of plants, chiefly Asiatic and European; a few species are American, and one species of the genus *Elaeagnus*—to which the oleaster belongs—is indigenous to Australia, while extending to India. This is *E. latifolia,* a Queensland species, a tall climber with clusters of small greenish flowers; the fruit is succulent, acid and somewhat astringent, and makes good tarts. Several exotic species are grown in Australia as ornamental garden plants.

Elaeocarpaceae, a family of trees or shrubs found in tropical or subtropical regions. The largely Asiatic genus *Sloanea* is represented by four species endemic in Australia. *S. australis* (Maiden's Blush), is a small tree with showy flowers, found in the coastal brush forests from Illawarra in southern New South Wales to Queensland, and known as 'kerabin' by the aborigines of northern New South Wales; it has a soft but durable timber, of a delicate rose colour when freshly cut, but fading into a light yellowish-brown; it is used for ornamental cabinet work. For the name-genus, *Elaeocarpus,* see BLUEBERRY.

Elder, SIR THOMAS (1818-1897), born at Kirkcaldy in Scotland in 1818, was trained for commercial pursuits and in 1841 aided his father to establish in England a branch of the firm—Elder & Co.—which his brother Alexander had just founded in Adelaide. In 1854 he migrated to South Australia to take over the management of the firm, which his brother had vacated, and shortly afterwards reconstructed it as Elder, Smith & Co., bringing in his brother-in-law Robert Barr Smith (q.v.) as a partner. The firm at once developed its operations in several directions, on the one hand financing the Moonta copper-mines and on the other occupying several thousand square miles of pastoral country and extending the area of settlement into previously unknown regions of the colony. This drew Elder into the work of exploration, and he actively encouraged nearly all the expeditions that between 1864 and 1894 penetrated the wilds of central Australia, especially those of Warburton, Gosse, Giles, and Lindsay (see EXPLORATION BY LAND). Apart from the supply of funds his most important form of help was the importation of camels (q.v.), which he acclimatized and bred at Beltana. His benefactions to South Australia were great. In 1874 he endowed the university of Adelaide with £20,000, and in 1884 gave £10,000 to the medical school, also contributing to the foundation of the chair of music, and founding a scholarship for graduates of Adelaide at the royal college of music, London. His will bequeathed to the university another £65,000. His gifts to the local museum, national gallery, and zoological gardens were valuable. He was an expert horse-breeder, importing valuable bloodstock from England, and until 1884 bred racehorses. He took little interest in politics, though in 1863-9 and 1871-8 he was a member of the legislative council. He died at Mount Lofty on 6 March 1897. (Kt. Bach., 1878; K.C.M.G., 1887; G.C.M.G., 1888.)—His elder brother Alexander (1815-1885) migrated to South Australia in 1839, founded the firm of Elder & Co. in 1840, and in 1853 returned to England, where he converted the London branch of the firm into an independent body and managed it until his death on 5 September 1885. In 1851-3 he represented West Adelaide in the legislative council. T.G.

Electric Rays or Numb-fishes, members of the family Narcobatidae, which includes a considerable number of species armed with organs for producing electric discharges. These are embedded in the soft flesh on each side of the head, and are composed of some hundreds of vertical, hexagonal cells, filled with a jelly-like substance, the ends of which are in contact with the integuments above and below. Their discharge has all the properties of electricity, producing a spark, rendering a needle magnetic, etc.; it is produced voluntarily, and evidently serves both to scare off would-be enemies and to stun and kill prey. A specimen of a common Australian species (*Hypnarce subnigra*) was observed to deliver 50 successive discharges within a space of about 10 minutes; these were intense at first, but gradually became weaker until they were scarcely perceptible. This species is plentiful in shallow waters on all coasts south of the tropics, and attains a length of over two feet. Two others occur in deeper waters, where they are occasionally taken by trawlers, together with a small species (*Narcine tasmaniensis*) that is represented in almost every haul of the trawl on the south-eastern coasts of Australia. A.R.McC.

Elephant Fish (*Callorhynchus millii*) is a ghost shark of the order Holocephali, characterized by a remarkable structure on the snout which somewhat resembles a short trunk. It is not uncommon in Victorian and Tasmanian waters, and is plentiful in New Zealand, where two tons of specimens have been taken in a single haul of a trawl-net. Though generally despised, the flesh of these fishes is quite palatable. Several species are known from southern oceans, all of which produce remarkable egg-cases surrounded by a broad flat expansion of horny texture. A.R.McC.

Elkhorn. See FERNS.

Ellery, ROBERT LEWIS JOHN (1827-1908), born at Cranleigh in Surrey on 14 July 1827 and trained for the medical profession, in 1851 migrated to Australia under the lure of the goldfields. Already interested in astronomy, he soon called public attention to the need of some institution where chronometers could be tested and nautical instruments adjusted for navigation in Australian waters; the Victorian government in consequence established an observatory at Williamstown, and made Ellery its first superintendent. His work in this connection is described under ASTRONOMY, q.v. From 1856 to 1874 he was director of the geodetic survey in Victoria. He took a prominent part in public life, especially in advancing the interests of education and science; he helped to found the Royal Society of Victoria (over which

he presided from 1856 to 1884), was a member of council of the university of Melbourne for many years, and a trustee of the public library; in 1873 he organized a local corps for signalling and torpedo work (which afterwards became the submarine mining engineers), and commanded it until 1889, retiring with the rank of lieutenant-colonel. In 1868 he was made a fellow of the Royal Society of London. He gave up his position as government astronomer in 1895, but maintained an active interest in the work, and lived practically next door to the observatory in the Melbourne domain until his death on 14 January 1908. (C.M.G., 1889.)

Emancipists, a term applied during the first half century of Australian history to men who had been, but no longer were, convicts, whether they had regained their freedom on the expiration of their sentences or (and this was the narrower connotation of the term, the first-mentioned class being technically 'expirees') had been granted an absolute or conditional pardon by the governor. Emancipists were thus distinct from free men on the one hand and convicts on the other. In principle emancipation was an act of grace based on the good conduct of the recipient; in practice it was often a reward for some particular service rendered. In the early days there was no definite rule for the mitigation of sentences. Macquarie decided to grant an absolute pardon only after 15 years' servitude in the case of a life sentence, or three-quarters of any other period to be served; and a 'conditional' pardon (the condition being continued residence within the colony) only after 10 years for a life sentence, or two-thirds of any other period to be served. This regulation—which was not strictly observed, even by Macquarie—had been made necessary by the increasing number of applications for relief. By 1820 out of a total population of 24,939 there were 1121 pardoned convicts, who with the 3255 expirees formed the bulk of the lower middle-class of the community. Phillip had been instructed to grant 30 acres of land to each emancipist, with a further grant if he were married; free rations were also issued for some months, and the loan of tools was provided for. But though some emancipists prospered on the land, others, untrained to agricultural work, or shiftless, sold their property soon after receiving it—despite the condition of five years' residence —or worked it so wastefully that it was soon exhausted. Bigge therefore recommended that land be granted only to emancipists who had accumulated a small capital. By 1820 emancipists held approximately 35,000 acres by grant and 50,000 by purchase.

Though some emancipists achieved considerable wealth, they found it of little value in crossing the gulf that separated free and freed —a distinction that 'cut deep into the social, economic and judicial structure of the colony.' A few emancipists were men of superior mental attainment, whose capacity demanded opportunity for development and expression; yet before Macquarie's arrival they were (with two exceptions) excluded from colonial society. Macquarie believed that freed men should have the opportunity of re-establishing themselves in society and be eligible for any situation for which, by a long term of upright conduct, they might prove themselves worthy. Soon after his arrival he gave practical effect to this belief by appointing two emancipists to the magistracy, and subsequently another two, despite the continued opposition of many officials and free settlers. Meanwhile his support of emancipist attorneys—among whom George Crossley was the most prominent—led to a serious dispute with Jeffery Bent (q.v.), the first judge of the supreme court. On the opening of the supreme court in 1815 Crossley, who had been allowed to practise in the previously existing courts of civil jurisdiction, entered a plea for access to the new court. Bent disallowed the plea on the ground that men struck off the roll in England could not properly continue to practise in an English colony. The two magistrates who sat with him were not prepared to support him, though two free attorneys, specially encouraged to migrate, were on their way to the colony. Bent therefore refused to constitute the court, which remained closed for two years. Macquarie also gave social recognition to a few leading emancipists, and invited them to his private table and society. This antagonized the military officers, who were the centre of all social gatherings in the young colony; it had been comparatively easy to dominate those of his own regiment (the 73rd), but on its recall in 1814 the officers of the 46th—and later the junior officers of the 48th—refused to admit emancipists into their company at the governor's bidding, and made the social barrier more rigid than ever. Macquarie's effort to secure the social re-establishment of emancipists was thus without much effect.

When Brisbane took charge of the colony, no emancipist magistrates sat on the bench. He had been warned by the colonial office that, although the principle on which Macquarie had worked was right, it was inexpedient to rouse the opposition of well-to-do free men by forcing it upon them without careful discrimination. In any case Brisbane took little part in social controversies, and his frequent disregard of official duties tended to increase the power of the official and free class—especially as during his term of office the attention of emancipists was concentrated on an effort to free themselves from certain unexpected legal disabilities. Before 1817 it had been generally assumed that the governor's pardon had the same force as a pardon issued under the great seal of England, and restored the party to all the privileges of a free subject. But the court of King's bench in 1817 decided that a governor's pardon had only the force of a pardon issued under the sign manual, the emancipist remaining in law a 'convict attainted' without power to maintain personal actions or acquire, retain or transmit property. This decision became effective in the colony in April 1820, and in January 1821 the emancipists held a meeting to petition the crown to remove these disabilities—the chairman and secretary of the meeting being sent to England to present the petition and urge its claim. Bigge supported them in this connection, and in the New South Wales act of 1823 a provision was inserted declaring that pardons already granted had the force of pardons under the great seal, though future remissions would have that effect only within the colony.

Brisbane before his departure for England accepted an invitation to a farewell dinner given in his honour by emancipists—an act which, in Darling's opinion, roused again their social ambitions and rendered them more susceptible than ever to the propaganda of the radical leaders—Wardell, Wentworth and their colleagues. With the growth of a popular party (consisting of the poorer free men, the colonial-

born, and the emancipists) during the later twenties and thirties, the political connotations of the word 'emancipist' gradually disappeared. But they died hard; the division of colonial society into 'exclusives' and 'emancipists' was still referred to by Bourke during his governorship, and proved a difficulty in the way of his extension of the jury system—it being argued, just as before trial by jury was allowed in any measure, that a free man tried by freedmen was not being tried by his peers.

The term 'emancipist' disappeared finally with the abolition of transportation, though the class to which it referred had already merged into a larger group.

'Emancipist' was from the first an officially recognized term for prisoners who had received a pardon before the expiration of their sentence, and later for all freedmen. The terms 'exclusive' and 'exclusionist,' often applied to those—usually officials, military men or free settlers—who opposed the admission of emancipists to full civic rights, never gained official recognition. They appear to have arisen about the beginning of Darling's term, probably as a nickname invented by Wentworth or his followers for propagandist use. Peter Cunningham in 1827 mentions 'exclusionists' as a word in common use. But officially the anti-emancipist party was known as 'free settlers;' Darling in 1825 calls them 'the old settlers,' and Bourke as late as 1833 calls them 'Emigrants'—a very misleading name.

Embids. See ISOPTERA.

Emeralds. See GEMSTONES.

Emperor Breams, tropical fishes of the family Lethrinidae. Species of the large genus *Lethrinus* are called 'island snapper' at Lord Howe Island and Norfolk Island, 'pig-faced bream' and 'sea bream' in Queensland, and 'yellow-mouthed sea perch' in New South Wales. They are valuable food-fishes, always prized by fishermen, and as they dry well in the hot sun of the tropics are particularly useful as a standby when fresh fish is not obtainable. They attain a large size, and are characterized by broad, scaleless cheeks and more or less pointed snouts, which give them a somewhat pig-like physiognomy. They are often very brilliantly coloured, and commonly live among coral reefs, where they find an abundance of crabs and shell-fish upon which to feed. A.R.McC.

Emu, a large flightless bird (*Dromaius novaehollandiae*), the sole living species of the family Dromaiidae, which with the cassowaries (Casuariidae) constitutes the order Casuariiformes, peculiar to the Australian region, and characterized by the structure of the feathers, which have a double form, as if two sprang from a single shaft; this is due to the fact that the aftershaft—which in other birds exists as a minute branch of the feather—is almost or quite as large as the main shaft.

The whole body of the emu is covered with brownish-black feathers. The small wings and rudimentary tail do not bear any specially large quills, resembling in this respect those of the New Zealand kiwi alone among living birds. The head and upper part of the neck have only a sparse clothing of short, black, hair-like feathers, which do not obscure the bluish colour of the skin of the neck.

The emu lays from 7 to 18 eggs in a depression in the ground, sometimes lined with grass, sticks, or leaves. The eggs are dark green, with a granulated surface, 5 to 5½ inches long and 16 to 24 ounces in weight. The breeding-season extends from April to November, and incubation—in which both sexes usually share—takes from 2 to 3 months. The chicks are sooty-black, with broad, white, longitudinal stripes. The adults make a deep drumming sound. Their food consists of grass, leaves, berries, and fruit.

Emus occur throughout Australia, except in the dense tropical scrubs of the east coast and

Emu.

the more settled districts—where they have been exterminated. They also formerly occurred in Tasmania, the insular race having been rather smaller than the mainland bird, with a lighter breast. Of the Tasmanian emu, which became extinct about 1860, only two specimens have been preserved, both in the British Museum.

When Australia was discovered distinct species of emu, of smaller size than the Australian, existed on King Island in Bass Strait, and on Kangaroo Island off the coast of South Australia. Both species were exterminated early in the 19th century by the settlers and sealers, who captured great numbers for food. Of the Kangaroo Island Emu (*D. peroni*) a single skin and two skeletons are preserved, in museums at Paris and Florence; the King Island Emu (*D. minor*) is known only from bones picked up on the island, and from the brief accounts of one or two early visitors to the island.

Footprints of the emu were seen by the Dutch explorer, Willem de Vlamingh, on the west coast in 1696; but the first specimen met with by Europeans was killed in February 1788, within half a mile of the present Sydney railway station, by a convict employed in shooting animals for Governor Phillip. The officers who examined it decided that it most nearly resembled the emu described in Goldsmith's *History of the Earth and Animated Nature*, the name being used by Goldsmith for the South American ostrich, or rhea; the bird was therefore named the New South Wales emu. The word emu is derived from the Portuguese 'ema,' a crane, and was at that period frequently used for any large bird, especially for the ostrich, cassowary, and rhea. It is now restricted to the Australian bird.

The emu is regarded as the typical bird of Australia, and with the kangaroo appears as a 'supporter' on the Commonwealth coat of arms. It was formerly figured on the twopenny postage stamp of New South Wales, and at

present appears to the right of King George's head on Australian postage stamps of various denominations. During the world-war a bunch of emu feathers worn in the hat was the badge adopted by the Australian Light Horse.

Emu Wren. See WRENS.

Endiandra, a genus of the family Lauraceae, consisting of trees with large globular fruits. It extends to Malaysia and India. The 15 species indigenous to Australia are confined to New South Wales and Queensland. *E. virens* (White Apple) is a tree of 40-50 feet with large whitish fruits; *E. Sieberi* (Cork-wood), reaches a height of 60-70 feet, and has a rough corky bark. The fruit when ripe has a lustrous blue colour, varying to purple, and is a favourite food of wood-pigeons. *E. glauca,* a 'teak,' growing up to 70 feet, has a handsome dark-coloured timber of aromatic fragrance.

Entada, a tropical genus of the family Leguminosae; one species, which is common in Asia, is also indigenous to Australia. This is *E. scandens* (Queensland Bean, Matchbox Bean), a strong woody climber that festoons the largest trees. The leaves have a common leaf-stalk 2-6 inches long, terminating in two tendrils (not always developed), which bear two pairs of leaves, each again divided into leaflets; pods woody (2-4 feet long, 3-4 inches broad) flat, and constricted between the seeds; seeds 10-30, nearly 2 inches in diameter. It is largely a coastal species; an air cavity in the seeds enables them to float in salt water for a long time without losing their power of germination. The large beans are eaten by the aborigines after a process of baking, pounding, and soaking; their dark-brown shell is hard and polished, and is used in both India and Australia for making ornamental boxes. The kernels are used by the Nepaulese for a hair-wash, and in Bengal for crimping linen.

Epacris, a genus of the family Epacridaceae, consisting of flowering shrubs. It contains 30 species, limited to Australia and New Zealand; 19 are found in New South Wales. The corolla-tube is cylindrical or bell-shaped, with five more or less spreading lobes; anthers wholly or partially enclosed in the corolla-tube; fruit a 5-celled capsule. The species are known generally as 'Australian heaths,' and are distinguished from the true heaths (*Erica*) by the epipetalous stamens and the form of the anther. *Epacris longiflora* (Native Fuchsia—a popular name shared by other plants) has handsome sprays of parti-coloured, drooping flowers, shading from crimson to white. It was grown and flowered in England in 1806. *E. paludosa* and *E. obtusifolia* (the latter with sweetly scented flowers) are swamp dwellers. *E. crassifolia* when growing on the seacoast is a robust plant with relatively large, coarse leaves; on the higher slopes of the Blue Mountains it grows in shady gullies, in the crevices of dripping rocks, and is a soft, matted plant with small leaves. A double-flowering variety of a handsome shrub, *E. onosmaeflora,* found by Allan Cunningham near Blackheath in the Blue Mountains, was raised at Kew gardens in England. The following species are endemic in the Blue Mountains: *E. rigida,* which grows on barren stony hills; *E. reclinata,* on dripping rock ledges in shady gullies; *E. apiculata,* a rare species found only on the higher elevations; and *E. Hamiltoni,* only found in a swampy area near Medlow, which has the softest foliage known in the genus.

Epacris longiflora.

Epacridaceae, a family of heath-like shrubs (rarely trees) largely indigenous to Australia, with representatives in New Zealand, Malaysia, and Oceania, and one species as far away as alpine South America. Over 300 species and 25 genera are known in Australia, divided into two large groups by their fruits; the Stypheliae, which bear drupes, and the Epacreae, which bear capsules. The flowers are white or red, occasionally blue, green, or yellowish. Many species are grown in European conservatories, to which they were introduced by early botanists.

Richea Gunnii.

The genus *Pentachondra* extends to New Zealand. The species are all diffuse or prostrate alpine undershrubs. *Acrotriche* is an endemic

genus of low shrubs, with insignificant greenish flowers and small red berries. *Richea*, the largely Tasmanian genus found only in alpine regions, is represented on the mainland by *R. Gunnii*. *Melichrus* is an endemic eastern genus of two species. See ASTROLOMA, DRACOPHYLLUM, EPACRIS, LEUCOPOGON, LISSANTHE, MONOTOCA, SPRENGELIA, STYPHELIA, TROCHOCARPA.

Epiceratodus. See CERATODUS.

Eremocitrus, a genus of the family Rutaceae, endemic in the drier parts of New South Wales and Queensland. The single species, *E. glauca* (Native Kumquat or Desert Lemon), was formerly placed under *Atalantia*. It is a rigid shrub or small tree, often armed with straight or recurved spines half an inch long. The young shoots are whitish with minute hairs; leaves thick, veinless, oblong, 1 to 1½ inches long. From the fruit—a globular berry about half an inch in diameter—a fairly good preserve is made, and an agreeable beverage may be made with its acid juice. This plant has a close-grained, bright yellow timber, with numerous brown streaks or veins; it takes a fine polish. Experiments are being made with the object of establishing a race of citrus plants with increased resistance to cold.

Eremophila, a genus of the family Myoporaceae, consisting of shrubs with solitary or few flowers in the leaf axils, comprises 91 species, all endemic in Australia. The calyx is divided into 5 segments; corolla-tube elongated and incurved, the upper portion obliquely two-lipped; stamens 4, in 2 pairs, often protruding; fruit dry or succulent. *E. maculata* (one of the so-called native fuchsias) is regarded as poisonous by some pastoralists and as a good fodder-plant by others; it is most dangerous when in fruit, and its effects always worst after rain. *E. longifolia* (Emu-bush—the emus feed on the fruit), the 'berrigan' of the aborigines of the interior, has a very brittle timber. Its leaves and bark yield a fair percentage of tannic acid, and are greedily eaten by cattle and sheep; it is said to be one of the first trees barked by rabbits during a drought. *E. Mitchelli* (Bastard Sandalwood) has a hard, brown, beautifully grained timber, with an aromatic odour resembling that of sandalwood; it provides handsome veneers for the cabinet-maker, and is said to be free from the attacks of insects. The leaves are relished by stock. The bruised leaves of *E. oppositifolia* (also called Emu-bush) are used by aborigines in the western districts for tanning wallaby and other skins used for carrying water.

Eriostemon, a genus of the family Rutaceae, consisting of showy flowering shrubs, usually found in poor sandstone country. The flowers are commonly pink or white, with a 5-cleft calyx and 5 imbricate petals; stamens 10, with hairy filaments; fruit carpels 5, the valves opening elastically and scattering the seeds with an explosive action; leaves with prominent oil-glands. There are 17 species, largely endemic, found in all States of the Commonwealth. *E. myoporoides* is cultivated as an ornamental garden plant. On a hot day the explosion of the ripe fruits gives the effect of distant rifle-shooting. *E. obovalis* is a cool-country species; *E. hispidulus, E. scaber* and *E. buxifolius,* low shrubs, are common on rocky

Eriostemon salicifolius.

ocean headlands and coastal sandstone country; *E. salicifolius* is very common in the Port Jackson district.

Eryngium, a genus of the family Umbelliferae, consisting of herbs with prickly leaves and flowers in compact heads or spikes surrounded by a ring of narrow prickly bracts. It is widely distributed in warm and temperate regions, and most abundant and varied in South America. Of the 4 species indigenous to Australia 2 are endemic. The calyx-lobes are rigid, with acute points, often prickly; petals with a much-inflexed long apex; fruit turgid, rough, and without oil receptacles. *E. rostratum* (Blue Thistle) has a rather striking appearance, but its tendency to spread, and the difficulties attendant upon its eradication when established, cause it to be regarded as a weed. Several exotic species are cultivated as ornamental garden plants, under the name of 'sea hollies.'

Erythrina, a genus of the family Leguminosae, consisting of trees or shrubs armed with conical prickles, widely dispersed and largely tropical. The flowers are large, usually red, in lateral clusters of 2-3 along the flower stem; pod 2-valved, slightly constricted and pithy between the seeds. *E. indica* is the Indian Coral-tree,' which ranges from northern New South Wales to northern Australia, and extends to India. It is largely cultivated as an ornamental tree; its soft porous wood is used for making toys, light boxes, etc., which are usually overlaid with a thick coating of varnish or lacquer. *E. vespertilio* (Bat's wing, Coral, from the shape of its leaves) has a soft, light wood from which

the aborigines make shields; they also use the hollowed logs as canoes.

Erythrophloeum, a small genus of the family Leguminosae, consisting of trees with mimosa-like leaves and small flowers in elongated cylindrical spikes. It has one species indigenous to Australia, and 2 in tropical Africa. *E. Laboucherii* is probably the 'leguminous Iron-bark' mentioned by Leichhardt in his *Overland Journey to Port Essington* (p. 242). It has a reddish wood, close-grained and very durable, said to be the hardest wood in Australia.

Esmond, JAMES, known as 'Happy Jim' while driving the coach between Geelong and Buninyong, left Victoria in 1848 for the Californian goldfields, where he succeeded in making wages only, and whence he returned to Sydney in 1850 on the same ship as E. H. Hargraves. Making his way back to Victoria he joined a timber-cutter in the Pyrenees, and while thus engaged met a Dr. Bruhn who advised him to look out for gold. Esmond accordingly, after examining the banks of Deep Creek, found gold on 1 July 1851 on the northern side of a hill opposite Cameron's station at Clunes, and made known his discovery in Geelong five days later. For his discovery the Victorian legislature awarded him £1000. See GOLD, DISCOVERY OF.

Etching. See ART.

Eucalyptus, a genus of plants of the family Myrtaceae, endemic in Australia and Tasmania. Its species (350 in number, besides some doubtless as yet undescribed) are widespread and abundant; while *Acacia* has more species, *Eucalyptus* has probably more individuals than any other genus known to science. It was founded on a specimen collected by David Nelson in 1777, during Cook's third voyage of discovery. William Anderson, the naturalist attached to Cook's second expedition, had noticed the Tasmanian 'gum-trees,' and had used to distinguish them the generic name *Aromadendron*; but Nelson's specimen (from Adventure Bay) was the first to be botanically described, L'Héritier in 1788 giving it the name *Eucalyptus obliqua*—now commonly known as messmate or stringy-bark. The generic name refers to the excellent shelter provided for the young blooms by the lid (operculum) which characterizes the genus; the specific name connotes the irregular growth of the leaf on the two sides of the midrib. Robert Brown in 1814 affixed to the genus the name *Eudesmia*, but *Eucalyptus* undoubtedly has the prior claim.

Apart from the operculum—which represents the petals—the genus is characterized by exceptional variation, seedlings, juvenile and mature foliage, buds, anthers, fruits, bark, and timber all developing extremely divergent forms. The flowers are usually white or cream-coloured, but a few species from Western Australia show crimson, scarlet, or yellow blossoms. Those of *E. ficifolia*, for instance, vary from pink to a dark crimson, with occasional divergence into white (the whole series of colours can be seen along the famous avenue in the King's Park at Perth); those of *E. macrocarpa* and *E. pyriformis* are red, of *E. miniata* orange-coloured, of *E. Preissiana* bright yellow. Another characteristic of the genus is the formation of well-marked 'suckers' or adventitious shoots; in most species the sucker-leaves, which represent juvenile foliage, differ considerably in form from the mature leaves, and are a valuable aid in identification. Two groups of eucalypts may be clearly differentiated by size only, the forest trees and the stunted mallees. The former may attain gigantic proportions; the remains of a Blackbutt (*E. pilularis*) near Bulli in New South Wales approximated 20 feet in diameter, monster Tallow-woods (*E. microcorys*) were found on the Lansdowne River, and specimens of the Mountain Ash (*E. regnans*) have in Victoria reached a height of 325 feet—the tallest in Australia. Some of the Karris (*E. diversicolor*) of Western Australia may closely approach this height, but no satisfactory records are available. The majority of eucalypts are, however, less than 150 feet high, and in the inland districts a tree of 100 feet is accounted a large one. Eucalypts as a rule are not umbrageous; the leaves in many species are, by a twist of the petiole, arranged vertically and offer little obstruction to the passage of light—a character which has given rise to the charge of shadelessness. In the coastal districts and tablelands, where the soil is rich and there is plenty of moisture, shelter, and warmth, the tree-eucalypts grow tall and straight, with a clear trunk and a short leafy canopy.

No satisfactory classification of the genus has yet been devised. Leaves, anthers, bark, have all in succession been taken to provide distinguishing standards, and all have been abandoned; the latest attempt is that of Baker and Smith, who use the quantity and composition of the essential oils for a discriminating feature. Classification by the bark, however, which was originated by Baron von Mueller (q.v.) for the tree-group, is the simplest so far suggested, and serves well enough for popular use. This provides five divisions—ironbarks, stringy-barks, woollybutts, bloodwoods (scaly-barks), and gums proper (smooth-barks).

Ironbarks have a hard, corrugated bark, ranging in colour from gray to black. The Broad-leaved Ironbark (*E. siderophloia*), a coarse-leaved species, grows plentifully along the northern coastal rivers of New South Wales; the White or Gray Ironbark (*E. paniculata*) is common in the Port Jackson district; the Narrow-leaved Ironbark (*E. crebra*), with long, pendulous leaves, is widely diffused; the Silver-leaved Ironbark (*E. melanophloia*), a somewhat straggling tree, is found chiefly in inland regions of low rainfall. The name 'ironbark' is also popularly applied to a few species whose barks differ more or less from the typical form.

Stringy-barks have thick, loose, and fibrous bark with the fibres laid longitudinally. Representative species are the Yellow Stringy-bark (*E. Muelleriana*), the Messmate (a name given in Victoria to *E. obliqua*, in parts of New South Wales to *E. amygdalina*), found chiefly on the tablelands, the Red Mahogany (*E. resinifera*), a denizen of the brushes of northern New South Wales, and the common Stringy-bark (*E. macrorrhyncha*) of the dry interior foothills.

Woollybutts include blackbutts, peppermints, and boxes, whose bark has a matted or felted fibre, not as coarse as that of the stringy-barks and comparatively smooth externally. Prominent among these are the coastal Blackbutt (*E. pilularis*); the Peppermints (*E. amygdalina, E. piperita, E. radiata, E. dives,* etc.); the New England Blackbutt (*E. Andrewsii*); the Argyle Apple (*E. cinerea*); and the Cut Tail (*E. fastigata*). Several boxes also come under this

group. *E. melliodora* is the common Yellow Box of the Riverina, the tablelands, and their western slopes; it is named from the colour of its inner bark. The Bimble or Shiny-leaved Box (*E. populifolia*) and the Coolabah (*E. microtheca*) are both found on the inland plains. The Swamp Mahogany (*E. robusta*), Bangalay (*E. botryoides*) and *E. Planchoniana*, (a large-fruited tree, confined to the northern rivers and the tablelands of New South Wales) are all coastal species with woolly barks.

(a)

(b)

Eucalyptus corymbosa, showing (a) bud with operculum, (b) flower.

Bloodwoods have a scaly bark, and frequently exude a reddish kino that gives the trees a blood-stained appearance. *E. terminalis* is an interior but chiefly tropical species, and *E. corymbosa* frequents the coastal sandstone. The bark of the Yellow Bloodwood (*E. eximia*) has a decidedly yellowish cast. The White Bloodwood (*E. trachyphloia*) and the Carbeen (*E. tessellaris*) are found in the north-western areas of New South Wales; the latter derives its specific name from its bark, which on the lower part of the trunk is blackish and arranged in cubes resembling those used to make a mosaic. Bloodwoods are usually found in poor soils.

Of the smooth-barked *Gums* the Spotted Gum (*E. maculata*), with its blotched trunk, is closely related to the bloodwoods, but lacks their distinctive scaly bark. The bark of gums is usually pale in colour—from whitish to bluish-gray or green—a small portion near the butt being often hard and either scaly or fibrous. The Gray Gums (*E. punctata* and *E. propinqua*) have a blotched bark, the gray part of which is rough, thus giving the trees a distinctive appearance. The White Gums (*E. haemastoma* and *E. micrantha*) are found on the eastern coast and tablelands; the Cabbage Gum (*E. coriacea*) and Sally (*E. stellulata*), the former with a white and the latter with a green or lead-coloured stem, are both cold country species. The Gum-top (*E. Smithii*), a tall tree of the southern tablelands, yields a rich oil. (*E. saligna*), the Blue Gum of the Port Jackson district, has a red timber which distinguishes it from other species known as blue gums. The Brown Gum (*E. Deanei*) is an umbrageous species, occurring chiefly on the northern tablelands of New South Wales. The Forest Red Gum (*E. tereticornis*) usually grows in dry situations, and in one or other of its numerous forms has an extensive range. The Tasmanian Blue Gum (*E. globulus*), which yields the well-known pharmaceutical oil, is found in Tasmania, Victoria, and southern New South Wales; it has been grown in malarial districts in Europe (especially in Italy) with considerable success, and has been successfully acclimatized in California. *E. rostrata* (Red or River Gum) is probably the most widely diffused member of the genus, and the most gregarious. It extends from Western Australia to Queensland, following the courses of the inland rivers and water-channels, and is the principal tree in the Murray red gum forest area; its kino is very well known to medical men, and appears in the British pharmacopoeia as an astringent for use in cases of diarrhoea, dysentery, and relaxed throat—though the kino of *E. calophylla*, a bloodwood from Western Australia, is said to be preferable.

Mallee, a term formerly used to denote shrubby eucalypts with a thickened rootstock from which rose a series of stems of equal size, now includes all low-growing species with or without the thickened bole. The species possessing this feature are for the most part found in western

New South Wales, northern Victoria, and parts of South Australia; many of them are more or less gregarious. Among the best-known are *E. uncinata*, *E. oleosa*, *E. calycogona*, *E. gracilis*, *E. incrassata*, and *E. dumosa*, the last-named being the mallee that forms that great 'scrub' of northern Victoria. The foliage of several species gives off by distillation a strong essential oil; that of *E. incrassata* is the most plentiful (112 oz. from 1000 lb. of leaves), that of *E. oleosa* the best solvent for amber, indiarubber, etc. Typical dwarf species with a normal root-stock occur in sub-alpine areas where the soil is poor and the climatic conditions are harsh. None of the mallees attain a size from which a commercial timber may be obtained.

Eucalypt *timbers* are classed as 'hardwood,' as opposed to the 'softwood' timbers of commerce. In the best kinds—e.g. the Gray Ironbark (*E. paniculata*)—the fibres are interlocked and the timber is heavy and dense, very durable and of great strength. They may be deep red in colour, as in the Red Ironbark (*E. siderophloia*), Red Box (*E. polyanthemos*), and Red Gum (*E. rostrata*); some are brownish, as in the Blue Box (*E. Baueriana*) and Gray Box (*E. hemiphloia*). In the dry districts of the eastern part of Western Australia the timber is nearly always cigar-brown. Species with a pale timber are the Blackbutt (*E. pilularis*) and Mountain Ash (*E. gigantea* and *Sieberiana*). Ironbarks and most gums have interlocked or non-fissile timber; that of the stringy-barks is usually fissile. Among the most important commercial timbers is the Jarrah (*E. marginata*), a Western Australian species and a great asset to that State. The timber is exceptionally durable and resistant to weather, and very valuable for building purposes; it is also useful for piles and other marine work, as it resists the teredo. The Karri (*E. diversicolor*) has a timber like that of the jarrah, but heavier and less easily worked, and is much in demand for bridge-building, wherever it need not come in contact with the ground. Like the jarrah it is a gregarious species, and confined to Western Australia. Another valuable Western Australian timber tree is the Tuart (*E. gomphocephala*) with a pale yellowish wood remarkable for hardness and strength, which has the valuable quality of shrinking very little in seasoning. The Mountain Ash of Victoria (*E. regnans*) has an exceptionally fissile timber, which does not twist when drying. It is very straight in the grain, easy to work, and particularly adapted for shingles, palings, etc., as it may be split until it is almost as thin as paper. The largest trees of this species, found in Gippsland, are inferior in size only to the giant redwoods (*Sequoia*) of California. The Tallow-wood (*E. microcorys*) has a strong timber, very durable either above or below ground. It is largely used for flooring and, owing to its greasy nature, is especially selected for ballrooms. It is an eastern species, occurring chiefly in New South Wales and Queensland. The Blue Gum of the Port Jackson district (*E. saligna*) has a useful reddish timber, remarkably uniform in texture, and singularly free from the twisted character frequently found in the genus. The timber of the River Gum (*E. rostrata*) is highly valued for strength and durability, especially for piles and posts in damp ground. It is used also for shipbuilding, railway sleepers, bridges, and wharves.

See von Mueller's *Eucalyptographia;* Bentham's *Flora Australiensis;* Woolls's *Contribution to the Flora of Australia;* Howitt's *Eucalypts of Gippsland;* papers by Deane and Maiden in the *Proceedings* of the Linnean Society of New South Wales; Maiden's *Forest Flora of New South Wales, Useful Plants of Australia,* and *Critical Revision of the Genus Eucalyptus;* Baker and Smith's *Research on the Eucalypts and Their Essential Oils* (2nd edn., 1920); and Grimwade's *Anthography of the Eucalypts.*

Eucalyptus Oils. It was the exudation from eucalypts, rather than their essential oils, that first attracted the attention of European visitors to Australia; Dampier, Banks, and Phillip all mentioned the 'red gum' as characteristic of the new kind of tree. But the Banks papers show that in November 1789 Sir Joseph received from Phillip a bottle of eucalyptus oil; and in 1790 John White, Phillip's surgeon-general, stated in his published *Journal* that an essential oil extracted from eucalypt leaves had been used by him with considerable success in treating 'cholicky' complaints, and that he had forwarded a quart of the oil to 'a Mr. Wilson' in England. This oil, therefore, was probably the first natural product of Australia to be exported to England. It was most probably distilled from the tree known as the Sydney Peppermint (*E. piperita*), which is still common round Sydney. Little more, however, was done in the direction of exploiting the oil until von Mueller in 1853 recommended the distillation of eucalyptus oil as an industry, and in the following year the first factory for its commercial production was established in Victoria by J. Bosisto. At that time the various constituents of the oils were undetermined and their comparative values unknown, so that the yield of oil became the chief guide when choosing species for distillation; as some members of the peppermint group yield oil in the greatest quantity, they were naturally employed for the purpose. The yield is still of considerable importance in the industry. It varies greatly, although it is fairly constant for each species; in the case of the most prolific eucalypts 30 to 40 lb. of oil can be distilled from 1000 lb. of green leaves and terminal branchlets, but some species yield less than 1 lb. of oil from the same bulk of leaves. Species with the lower yields are consequently neglected unless the oil constituents are of exceptional value—e.g. *Eucalyptus Macarthuri* of New South Wales and *E. citriodora* of Queensland. *E. Macarthuri* gives an oil rich in the valuable alcohol geraniol and its ester geranyl-acetate and the oil of the Queensland tree consists largely of the aldehyde citronellal.

Serious study of the constituents of these oils dates from 1870, when the oil of *E. globulus* was investigated by Cloëz in France; he named its chief constituent eucalyptol, but this was shown later (by E. Jahns) to be identical with cineol. Since that time the constituents occurring in the oils of 180 species of *Eucalyptus,* have been determined, and no less than 40 distinct chemical substances have been isolated and characterized from the several oils. For pharmaceutical purposes the chief constituent demanded is cineol (eucalyptol) and to satisfy requirements in this direction only those species are utilized which both for yield of oil and for cineol content give the best return. Such species are *E. polybractea, E. Smithii, E. Australiana, E. cneorifolia*; a few others are employed in restricted localities by certain distillers. The proportion of cineol in the oil required by the American pharmacopoeia is 70 per cent, and by the British 55 per cent. The American require-

ment is not easy to satisfy as very few species yield oils of this character, but the more moderate British standard can be met with oils of numerous species. If desired, pure cineol may be employed instead of the oil, as this constituent can be readily frozen out, and then by mechanical treatment removed from the terpenes and other bodies which cannot be frozen.

In 1910 Henry Lavers at Broken Hill in New South Wales, discovered the fact that a small quantity of certain eucalyptus oils when added to finely ground minerals, had the property of separating the metallic sulphides from the gangue by a flotation process. The oils most suitable for this purpose are those consisting largely of the terpene phellandrene and the ketone piperitone, and are distilled from *E. dives* and *E. phellandra*. The yields from these species are good, and, as they are plentifully distributed in both New South Wales and Victoria, an abundance of oil can be cheaply prepared for flotation purposes. Eucalyptus oils are also utilized in other directions—in the manufacture of numerous proprietary articles, for soap-making, for disinfectants, and as solvents. They also offer opportunities for scientific research, and products of considerable economic value have been manufactured from certain of their constituents.

Eucalyptus oils are readily procured from the leaves by a simple process of steam distillation, numerous types of stills being employed. The simplest consists of an ordinary cubic 400-gallon iron tank, fitted so as to prevent the escape of steam except through the pipe leading to the condenser. This tank-still, containing the leaf material and about eight inches of water, is placed on a suitable platform and a fire lighted beneath. Condensation of the escaping steam (which conveys the oil) is accomplished by passing it through a worm placed in a separate vessel filled with water, or by running the outlet-pipe sufficiently far along a running stream to secure complete condensation. In the receiver the oil and water separate, the oil floating on the top of the water, so that it may be readily removed. Larger types of still require a boiler for the production of the steam; in these the digesters are often of considerable size, and are frequently sunk in the ground. In Victoria these large digesters are usually constructed of wood, but in New South Wales iron digesters are employed. The crude oils first distilled are seldom of sufficient purity to satisfy commercial requirements, and must undergo a process of rectification, which is not often undertaken by the primary distiller.

The economic value of the industry cannot be accurately ascertained, but besides the oil utilized in Australia large quantities are exported to Britain and the United States, the export value growing from £60,000 in 1916-17 to £107,000 in 1920-21. In 1922, however, only £24,000 worth was exported. H.G.S.

Eucalyptus oils may be used as disinfectants in several ways either mixed with lard, paraffin, or other neutral oil, or with water as a general disinfectant. The watery mixture may be employed as a spray, or the oil itself may be scattered over the floor with the expectation that it evaporates and disinfects the atmosphere; when mixed with oil, its disinfecting power is very feeble—much less effective than that of phenol or carbolic acid. Ointments containing eucalyptus oil act as cutaneous stimulants rather than as disinfectants. The older oils are more efficacious than fresh or recently distilled oils, as they contain more acid. During storage this acid is developed, and reacts upon the oil, giving rise to products that are more active. The most acid oils, however, when made into ointments are never so good as carbolic oil.

The vapours of the oils have a good disinfecting action, but they must be used in conjunction with water vapour, or (what comes to the same thing) the infected material exposed to the vapour should be moist. For example, if an influenza mask were put into a closed box whose walls and bottom were sprinkled with the oil, disinfection would depend upon whether or not the mask had been wetted when put in. A damp mask would be sterile in an hour at summer temperature, but a dry mask would require three days.

As a spray for rooms, an emulsion of one part of the oil in three hundred parts of water would be as effective as a solution of one part of phenol (carbolic acid) in one hundred parts of water. The eucalyptus oil, too is the cheaper and less dangerous. Such an emulsion destroys ordinary bacteria in half an hour. The efficiency of the oil is increased by adding acid to the water employed in preparing the emulsion. An ounce of vinegar added to a gallon of the water would double the activity of the oil.

The pure oil formerly known as eucalyptol, but now as cineol, is from 3 to 3½ times more active than phenol when tested by giving the disinfectants half an hour to act upon *Bacillus coli communis* at 20° C. (68°F.). This is the most effective exposure; the efficiency of the pure oil is lower with shorter or longer times. It may be said to be a slow disinfectant. Phenol exerts its maximum effect in about a 20th of the time; that is to say, the germicidal activity of phenol begins to slow down in a minute and a half, that of cineol in 30 minutes. If time is an object, phenol is preferable to cineol; but if, as in many cases, the infected material can lie in the disinfectant for an hour or more, cineol is indicated. The two disinfectants have the same efficiency in five minutes at 20° C. in dilutions of 1 to 75.

The ordinary eucalyptus oils are mixtures of cineol with other constituents. Their disinfecting powers vary, much depending upon their age. The rectified oil of *E. cinerea* after some years' storage was six times as active as phenol, while recently distilled specimens were from 2½ to 3 times as effective. The variety of *E. australiana* that grows on the ridge of the Dividing Range furnishes one of the most effective oils. Its phenol number is six, it contains phellandrene, and can only be used for disinfecting purposes. The rectified oils of *E. Smithii* and *E. australiana* (1st hour oil) are medicinal oils and good disinfectants, with phenol numbers ranging from 3½ to 4; indeed most of the oil numbers are above three, probably because they contain a majority of constituents that have thrice the efficiency of phenol. Aldehydes are the most powerful of the minor constituents. Oils containing much pinene or sesquiterpene are likely to be poor disinfectants; those tested were found to be weaker than phenol. R.G.S.

Eugenia, a genus of the family Myrtaceae, consisting of trees or shrubs chiefly tropical or subtropical. The calyx-tube is almost globular, the lobes short or prominent; petals 4, rarely 5; stamens numerous, free or collected in 4 bundles; fruit a berry or drupe, or almost dry and with a fibrous coat; leaves opposite. *E.*

Smithii (Lilly-pilly) has a profusion of white fruits with a purplish tint, which are eaten by aborigines and small boys and are acidulous and wholesome. The fruit of *E. myrtifolia* (Brush Cherry) makes a good preserve, and its red juice, when fermented, yields a wine with a bouquet. *E. Jambolana* (Durobbi of the abor-

Lilly-pilly.

igines) has a fruit resembling a plum, with an astringent but sweetish flavour. The fruit of *E. Ticrneyana* is produced in large quantities, and is used for making jam by the settlers round Rockingham Bay. *E. Ventenatii* (Drooping Myrtle), a tree of charming habit, has beautifully marked timber of a greyish hue, close-grained, hard, heavy, and tough. It is used for poles of drays, ribs of boats, and flooring boards of verandahs. *E. suborbicularis* has wood with peculiar concentric rings several inches apart. Out of the trunk of this tree the Johnstone River (Queensland) natives make their canoes.

Euphorbia, a large and widely distributed genus of the family Euphorbiaceae, consisting of herbs or shrubs which have a milky, acid juice. The 30 species indigenous to Australia range right across the continent. *E. Drummondii* (Caustic Weed) is a succulent, prostrate herb abundant in the drier regions. It is eaten greedily by stock, and is wrongly reputed to be poisonous. The aborigines use an infusion of the plant medicinally, and are said to use the juice for attaching small feathers to native bees, so that they may be followed to their nests to obtain the honey. *E. pilulifera* (Asthma Herb) has acquired a reputation in pulmonary complaints, and is still sold by herbalists. Though indigenous, it is a common tropical weed.

Euphorbiaceae, a very large family consisting of trees, shrubs, or herbs which frequently contain a milky juice; most abundant within the tropics, rarer in colder climates. More than 40 genera with 276 species are indigenous to Australia. *Breynia* has four indigenous species, ranging from New South Wales to northern Australia. *B. oblongifolia* is an ornamental shrub, with a blackberry-like fruit and a straw-coloured wood; the leaves turn black when dried. *Bertya,* a genus ranging from Western Australia to Queensland, has 15 indigenous species. The branchlets of *B. Cunninghamii* exude a clear gum resin, which gives a hyaline appearance to dried specimens when held up to the light. The resin is yellow, and has a pleasant, bitter taste, something like wormwood. *Bridelia,* a warm-country genus, has four indigenous species, which extend from northern New South Wales to northern Australia. *B. exaltata* (a tree of 90-100 feet) is the 'biggera-biggera' of the northern New South Wales aborigines. It has a brown, hard timber somewhat resembling walnut. *B. faginea,* a tall shrub with ornamental red berries, also has a useful timber. *Dissilaria* is a genus with three indigenous species, extending from Queensland to northern Australia. *D. baloghioides* is a 'teak,' with a hard, durable timber, brown in colour but darkening towards the centre. It resembles the wood of the English apple, and might be used for similar purposes. The aborigines call it 'currungul.' The genus *Hemicyclia* has three indigenous species, ranging from New South Wales to northern Australia. *H. australis* is an ornamental tree of 40 feet, bearing succulent, bright red, oval fruits. It has a hard, close-grained timber, yellowish when fresh. See ALEURITES, ANTIDESMA, BALOGHIA, BEYERIA, CROTON, EUPHORBIA, EXCAECARIA, HOMALANTHUS, MALLOTUS, PETALOSTIGMA, PHYLLANTHUS, RICINOCARPUS.

Eureka Stockade, THE. To meet the expense of securing order on the Victorian goldfields, and to restrain unauthorized mining on waste crown land, a local act of January 1852 imposed on all diggers a licence fee of 30 shillings per month, the penalty for mining without a licence being £5 for the first offence and afterwards imprisonment for terms up to 6 months. Clause 7 of this act appropriated half the recovered penalties to the use of the informer or prosecutor—a provocative and irritating provision. In December 1853 an amending act reduced the fee to £1 per month, but did not alter the diggers' great grievance—that they could be imprisoned for not having the actual licence on them, though their possession of one could be proved from the official record. They were, too, unrepresented in parliament, though in 1854 the population on the Ballarat goldfields was estimated at 20,000.

Sir Charles Hotham (q.v.), who reached Victoria in June 1854, was alarmed at the depleted state of the treasury and the growing expense of goldfields administration, and ordered the police to redouble their exertions in collecting the fees. To miners barely making rations the payment of £12 per annum was impossible, and doubtless hundreds did endeavour to evade payment, but the innocent suffered with the guilty. The police, too, had been largely recruited from Tasmania, and many were ex-convicts who had risen to be gaol-warders; some, in addition to their venality, showed a rough brutality. These grievances were common to all the Victorian fields, and had under Latrobe's administration produced riots at Beechworth and Castlemaine. Bendigo was the malcontents' headquarters, and in the first months of Hotham's regime even

Bendigo became orderly. Ballarat had always been the most domestic of the goldfields, renowned for its schools and for its quietness on Sundays. But on the night of 6 October a miner named James Scobie was killed at the Eureka Hotel near Ballarat, and the murdered man's brother accused the proprietor (Bentley, a Tasmanian ex-convict) of the murder. Bentley was brought up before a magistrate, and discharged. The miners were indignant; a meeting was called for the 17th, and a committee appointed to demand a fresh prosecution. The meeting itself was orderly, but towards the end of it a cry was raised that the police (who had been ordered to protect the hotel) were trying to disperse the meeting, and the miners, becoming furious, swept aside the police, smashed the windows and furniture, and burned the building. The police arrested three men, who could not be proved to have been ringleaders or active in the riot, but were sentenced to three, four, and six months' imprisonment. At an indignation meeting held on 11 November on Bakery Hill the Ballarat Reform League was formed, with J. B. Humffray (a Welshman) as its first secretary, and Peter Lalor (q.v.), Frederic Vern (a Hanoverian and a talker), Raffaello (an Italian teacher of languages), Timothy Hayes (an Irishman) and George Black (an Englishman of good education and considerable intelligence) as prominent members. A deputation of three men waited on Hotham to demand the release of the prisoners, but he had already sent additional troops to Ballarat, and on the 27th refused the demand. Meanwhile the troops, arrived in Ballarat, had given considerable offence by marching in with fixed bayonets; their captain's refusal to parley with 'rebels' fired the crowd, which threw itself on the convoy, overturned a waggon, captured another, and injured three or four soldiers. This action, it should be remembered, was condemned by the leaders of the League. On 29 November Black, Humffray and Kennedy reported to a mass meeting held at Bakery Hill the result of their deputation, and pleaded for further negotiation. Lalor carried a proposal to elect a central committee, Vern proposed a burning of the obnoxious licences and the meeting pledged itself to burn all licences and to unite and protect anyone arrested for having none. Bonfires were lighted, and the licences burnt there and then. Next day (30 November) the police were ordered to make a specially vigorous licence-hunt; a squadron of mounted troopers was received with volleys of stones and an occasional pistol-shot; Commissioner Rede endeavoured to read the riot act, but was told the licences were all burned and that, if he liked, the whole camp would surrender—an obviously absurd proposal, as it would have been impossible to guard so many prisoners. When the troops marched back to camp, the diggers hastened to a conference with the leading spirits of the League. Peter Lalor was elected leader, and under a blue flag adorned with the stars of the Southern Cross, which had already been flown at the meeting of the 29th, the assembled diggers swore 'to stand truly by each other, and fight to defend our rights and liberties.' An area of about an acre on the Eureka claim was hastily enclosed with piled-up mining slabs, building timber, and any other material handy. A deputation sent to the camp demanded the release of the morning's prisoners and the cessation of licence-hunting, but the commissioner refused flatly, saying that the agitation was only a cloak to cover a democratic revolution.

On 1 December the occupants of the stockade were hard at work by 5 a.m. drilling, and improving the barrier, and a German blacksmith was fashioning pike-heads. But neither food nor ammunition was available within the stockade, and many men left it in search of these commodities, so that by the evening of the 2nd not more than 200 remained within. Spies informed the commissioner of the situation, and about 4.30 a.m. on Sunday morning (3 December) a troop of 276 men was marched silently to the stockade. Of those within about 50 had rifles; there was also a troop of Californian diggers armed with revolvers and another of Irishmen with pikes; many of them were asleep when the signal gun was fired and a storming party of 64 'rushed' the stockade. In the first volleys several men fell on both sides, but the line of advancing bayonets, flanked on both sides by cavalry and mounted police, was too much for the diggers. They turned to seek shelter, and all was over. Of the military force Captain Wise and four private soldiers were killed, and about a dozen injured. Sixteen miners were killed, and at least eight others died of their wounds—probably many died in hiding; 114 prisoners were taken, but all were discharged except 13 (including Hayes and Raffaello) who were held to take their trial for high treason. Lalor, badly wounded, managed to escape: so did Black and Vern, though the government offered £500 for the apprehension of Vern, and £200 each for Black and Lalor. Ballarat was put under martial law at once. On the 5th Sir Robert Nickle (q.v.) arrived with reinforcements. He blamed the rebels, but listened to the miners' grievances, and his just and conciliatory treatment had a soothing effect on the population—as did his announcement that the governor had appointed a commission to enquire into their wrongs. On the 9th the ban of martial law was withdrawn, though the miners declared they preferred it to police rule.

The trials began in February 1855 and two men were acquitted without needing to defend themselves. The attorney-general postponed the rest of the trials until March, but without effect —all the men appeared, pleaded, listened to the charges, and were also acquitted without being called on for a defence. When the last prisoner walked free, the rewards for the capture of the missing men were withdrawn. While the diggers' grievances were undoubtedly great, and the severity of the police administration was officially condemned by a royal commission appointed by Hotham to enquire into the whole trouble, it is also certain that some of the League's leaders had in view far more than a mere redress of grievances. Lalor, Humffray, and Black were probably inspired solely by indignation, but several of the Italian, German and American leaders hoped to make the movement a political one, and to establish a republic.

See H. G. Turner's *Our Own Little Rebellion*, and Withers's *History of Ballarat* (1870: 2nd edn. 1887). Ross's *Eureka* (Melbourne, 1914) summarizes the rebellion from the rebels' standpoint; it admits that 'the authenticity and accuracy' of Turner's facts are 'unchallengeable,' but controverts his opinions and deductions.

Evans, George Essex (1863-1909), born in London on 18 June 1863 and educated at Haverford West and in Guernsey, migrated to Australia in 1881 to gain bush experience, and a little later joined his brother J. B. O. Evans

in farming land near Allora in Queensland. He soon found, however, that his real bent was for literature, and became a contributor to the *Queenslander*, the *Brisbane Courier*, and the Sydney *Bulletin*. In 1888 the Queensland government made him district registrar at Toowoomba, and in later years employed him to write up the State for immigration and exhibition purposes. In 1891 Evans published in London his first book of verses, *The Repentance of Magdalene Despar*; pursuing thereafter his own aims, he to a great extent wasted his powers on trivial and uncongenial subjects, and injured himself by attempting to become a publisher as well as an author. His editorship of *The Antipodean* (an annual published in 1892, 1893, and 1897) was a failure, and only with the winning of the official prize for an ode on the inauguration of the Commonwealth did he attain fame outside Queensland. His *Loraine*, a long narrative poem dealing with life on a sheep-run published in Melbourne in 1898, afterwards attracted attention in London, where he was reckoned one of the half-dozen outstanding Australian poets. He was in fact a cultured craftsman with a poetic turn of mind; the best of his work (including a good deal of the *Loraine* volume) is contained in *The Secret Key*, published at Sydney in 1906. He died at Toowoomba on 10 November 1909.

Evans, George William (1778-1852), born at Warwick in England and apprenticed while still a boy to a surveyor and architect, left home in or about 1796 to go to the Cape of Good Hope, and secured a good post in the government dockyard there. When in 1802 the Cape was handed back to the Dutch, Evans was picked up by H.M.S. *Buffalo* on her way to Australia and reached Sydney on 16 October, with, it is said, a commission as deputy-surveyor in his pocket. This was not at first of much use to him; the best King could do for him was to make him (on 2 November) storekeeper at Parramatta and give him a 90-acre farm. On 10 August 1803, however, Grimes the surveyor-general having gone home on leave, Evans was appointed his locum tenens. In March 1804 he was sergeant-major of the Parramatta volunteer company, but by August had been promoted to lieutenant. In July of that year he was one of the officers charged with taking a general muster of settlers, and entered his own land as 539 acres, 30 being laid down as orchard. A brief entry in a schedule of Governor King's states that on 22 February 1805 he was 'discharged for Fraud,' but no details of this affair are known. He then settled at the Hawkesbury, and was one of the pro-Bligh party there in 1807; in spite of this Paterson during 1809 made him assistant-surveyor at Port Dalrymple, and Macquarie in 1810 confirmed the appointment, but for three years his work was done in New South Wales, and it was only in September 1812 that he actually took up the Tasmanian appointment, proceeding to Port Dalrymple in the *Lady Nelson* with James Meehan (q.v.). After a few months he was recalled, and sent in November 1813 to confirm and extend the discoveries of Gregory Blaxland's party in the Blue Mountains; his work on this journey, and on all those referred to later, is narrated under Exploration by Land. Macquarie approved it so highly that he sent Evans back to Tasmania in May 1814 with an order for 1000 acres to be selected on the Derwent (exclusive of 300 acres which had been given him on his first trip), the services of four convicts, a right to choose an allotment for his Hobart residence, and a supply of stock on deferred payment terms. In January 1815 the restless Macquarie recalled him once more to act as guide in the projected official tour to the Bathurst plains which he had discovered in 1813; this resulted in the discoveries of May-June, which placed the Lachlan River on the map and much delighted Macquarie's heart by opening up 'a very great Extent of Country possessed of Many and very important Advantages for a Numerous Population.' This was probably the apex of Evans's career; he had opened up land of immense value to the settlement, obtained the approbation (both expressed and confirmed by gifts) of his immediate ruler, and obtained from the English secretary of state a statement that he (Bathurst) could not 'refrain from expressing my Sense of the Exertions Perseverance' (*sic*) 'of Mr. Evans.' On reconsideration, however, Bathurst thought him not sufficiently educated to report usefully on his discoveries, and on 18 April 1816 directed that in future he should be associated with someone 'of more scientific Observation and of more General Knowledge.' When, therefore, Macquarie in 1817 fitted out an expedition to carry still farther the exploration of the western plains, he put Oxley in command, laying stress in his report to Bathurst on Oxley's 'general and Scientific Knowledge and liberal Education;' Evans was made second in command, both as an act of justice and because his previous experience would make him very useful. In 1818 a second Oxley-Evans expedition made still more important discoveries; Oxley on his return handsomely acknowledged the help Evans had given him, and Macquarie, when asking permission to recompense Oxley with a lump sum, suggested that Evans should receive at least half as much as might be given his superior. Bathurst agreed, and, as Oxley was given £200, Evans received £100.

From 1818 onwards Evans was employed on his Tasmanian duties, which were arduous and ill-paid. His pay as deputy-surveyor-general for the settlement was 7s. 6d. per day; half his year was spent in the field, often in bivouacs, and the other half barely sufficed to bring his office work up to date. In 1821 Macquarie managed to double his salary by giving him the additional appointment of collector of quit-rents and inspector of roads and bridges. In 1825 he asked permission to retire on a pension, partly because of ill-health, partly because he had been severely—and, it would appear, unjustly—denounced by Arthur for allowing a settler too much land (Evans proved that he had done this under direct instructions from Sorell, the previous governor). At the critical moment Darling arrived, on his way from England to take up the governorship of New South Wales; Arthur put his case, and Darling welcomed the opportunity of providing a billet for his brother-in-law Edward Dumaresq (see Dumaresq, Henry); Evans was therefore retired on a pension of £200 a year, just when Bathurst—knowing nothing of events in Tasmania—had made him surveyor-general of the new colony. On 16 November 1826 he sailed for England. But he had been too long in Australia to find England restful. In 1832 he returned to Sydney and opened a circulating library and stationer's shop in Bridge-street; in the *New South Wales Calendar* for 1833 he and

three others (Ralph Mansfield, q.v., among them) appear as 'booksellers,' the first who used that name in Australia. When in 1834 Mansfield transferred his stock and goodwill to Evans, the ex-surveyor became the doyen of the trade, and is often thought to have been actually its pioneer. Mrs. Evans meanwhile had established a girls' school at first on Miller's Point, afterwards in Castlereagh-street. In 1842 the family went back to Hobart, and there Evans died on 16 October 1852.

His chief work for Australia was his series of discoveries, but Bathurst was undoubtedly right in suggesting that he was not fully equipped for exploiting them. His maps are frequently inaccurate, even for an explorer's. In his survey of Tasmania he avowedly depended mainly on the careful work of his assistants. And, though his personal integrity seems unassailable, he was on occasion more pliant to the wishes of his superiors—especially to Sorell's—than was fitting in the holder of so responsible a position. This pliancy accounts for the questionable transactions which Arthur denounced—and may have had something to do with the unexplained dismissal by King. Against it we must place the approval of Macquarie, no easy master, who throughout his term of rule took unmistakable pleasure in setting forth Evans's services to the colony, and in asking that they should be suitably rewarded.

Everlastings. See HELICHRYSUM and HELIPTERUM.

Ewing, SIR THOMAS THOMSON (1856-1920), born at Pitt Town on the Hawkesbury River on 9 October 1856, was in his early life a licensed surveyor, but in 1885 entered politics as member for the Richmond (1885-94), and later for Lismore (1894-1901), in the New South Wales assembly. Lacking the purely partisan qualities and possessed of overmuch humour for a politician, he yet did good work as chairman of the works committee and of a royal commission on railway extension within the city of Sydney. Representing a constituency on the border of Queensland—to which colony it had always desired affiliation—he was from the first an ardent and effective federationist, and left State politics in 1901 to become member for the Richmond in the federal parliament. Here he attached himself to Alfred Deakin, and in the Deakin ministry of 1905-8 was, first, vice-president of the executive council and then (from 24 January 1907) minister for defence. In the latter capacity he strongly advocated compulsory training of young citizens for military and naval service, and introduced a bill to effect this. In 1910 he retired from politics, devoted himself to the management of his lands on the Tweed River, and died in Sydney on 15 September 1920.

Excaecaria, a widespread tropical genus of the family Euphorbiaceae, with three species indigenous to Australia, which range from New South Wales into northern Australia. *E. Agallocha* (Milky Mangrove or River Poison tree) exudes, when an incision is made in the bark, an acrid, milky juice, so volatile that no one can gather a quarter of a pint without being affected by it. The symptoms are a burning sensation in the throat, sore eyes, and headache. A single drop falling into the eyes is said to cause blindness. The natives of eastern Australia, as well as those of New Guinea, use this poisonous juice to cure leprosy, but in Fiji the patient is fumigated with the smoke of the burning wood. In India the sap of the tree is called 'tiger's milk,' and is applied with good effect to inveterate ulcers. A good caoutchouc may also be prepared from the milk. The tree has a light, soft wood, which would answer for carving and marqueteric. *E. Dallachyana* and *E. parvifolia* also have useful timbers.

Exclusionists. See EMANCIPISTS.

Exhibitions. *New South Wales.*—A show of exhibits from New South Wales for the Paris exhibition of 1855 was opened by Sir Charles Fitzroy in the large hall of the Australian museum on 14 November 1854, and closed on 9 December. In 1861 a display of exhibits for the London International Exhibition of 1862 was opened on 16 October in the lecture hall of the Sydney school of arts and closed on 7 November. Stuffed alpacas (q.v.) and llamas were among the exhibits, to show that these animals could be successfully reared in Australia. In 1870, to celebrate the centenary of Captain Cook's landing in Australia, an intercolonial exhibition was opened on 30 August in the exhibition building at Prince Alfred Park; it was closed on 30 September. A second intercolonial exhibition was opened in Sydney on 3 April 1873, and a third on 6 April 1875. On 17 September 1879 was opened the first international exhibition held in Australia, the 'Garden Palace' being specially erected for the occasion in the inner domain; it closed on 20 April 1880. The building, with many exhibits that had been left in it, was totally destroyed by fire on 22 August 1882. On 24 January 1888 an intercolonial agricultural exhibition, promoted by the Agricultural Society with the assistance of the government, was opened in connection with the centenary celebrations. A number of smaller and more specialized exhibitions were subsequently held in Sydney; among these mention may be made of the all-Australian exhibition of manufactures, products, arts, and industries, which was held from 7 October to 18 November 1922.

In *Victoria* an exhibition of the products to be sent to the Paris exhibition of 1855 was opened on 17 October 1854, and closed on 12 December. In 1861 the exhibits for the International Exhibition of 1862 were on show in Melbourne from 1 October to 7 December. The first intercolonial exhibition in Victoria was opened on 24 October 1866 in an exhibition building erected in connection with the Melbourne public library; it closed on 23 February 1867. New Caledonia, Mauritius, and the Dutch Indies were represented at this exhibition. The Victorian products to be shown at the London International Exhibition of 1873 were on show in Melbourne from 6 November 1872 to 18 January 1873. On 2 September 1875 an intercolonial exhibition was opened, preparatory to the sending of exhibits to the Philadelphia Centennial Exhibition of 1876. On 1 October 1880 the first international exhibition held in Melbourne was opened in permanent buildings erected for the purpose in Carlton Gardens; it closed on 30 April 1881. The buildings still stand, and are in part used to house the Victorian legislature. In 1888 a Centennial International Exhibition was held in connection with festivities arranged to commemorate the first British settlement in Australia; it was opened on 1 August, and closed on 31 January 1889. The Bendigo Exhibition, held to commemorate the jubilee of the gold discoveries, was open from 13 November 1901 to 14 May 1902. On 23 October 1907 was opened the first international exhibition of women's

work; it closed on 3 November. The first all-Australian exhibition promoted by the Australian chamber of manufactures was open in Melbourne from 13 September to 8 November 1913.

The first exhibition in *Queensland* was opened in Brisbane on 29 October 1861. An intercolonial exhibition promoted by the National Agricultural and Industrial Association was held at Bowen Park, Brisbane, from 20 to 28 August 1876. The first international exhibition in Queensland was organized to commemorate the Queen's jubilee in 1897; it was opened at Bowen Park on 5 May, and closed on 14 August. The first international exhibition in *South Australia* was arranged by Messrs. Joubert and Twopeny at the close of the successful Melbourne exhibition of 1880-1; it was opened in Adelaide on 21 July, and closed on 24 September. In 1887 a second international exhibition was held to commemorate the jubilee both of Queen Victoria and of the founding of the colony; it was opened on 20 June, and closed on 17 January 1888. An exhibition was held in *Western Australia* from 21 November to 31 December 1881. The first international exhibition held in *Tasmania* was opened at Launceston on 25 November 1891, and closed on 22 March 1892. The international exhibition at Hobart was held from 15 November 1894 to 25 May 1895. On 1 January 1913 an inter-State exhibition, to show the progress of Australia since the inauguration of the Commonwealth, was opened at Launceston under the auspices of the Australian Natives' Association.

Exploration, French. The fact that the whole continent of Australia has been colonized and is now possessed by people of British origin, is due mainly to the maritime supremacy of Great Britain, won after half a century of conflict with the French nation, which existed during the critical years (1810-1840) of Australian colonization. There is no historical evidence to justify the belief that France at any time formulated plans for occupying any portion of Australia. But there is an abundant literature to show that, long before Australia was known to geography even in outline, as well as long after the ownership of the country was settled, the problems presented by southern regions to men of science and to explorers appealed to the intellectual alertness of the French; and voyages undertaken by them occupy a considerable part in the story of Australian discovery. Among these, however, need not be reckoned a supposed voyage of Binot Paulmier de Gonneville, for whom it has been claimed that in 1503-4 he was blown by storms away from the African coast and spent six months in 'Southern India,' which he named 'Terre Australe.' Unfortunately the story depends entirely on the authority of a self-styled 'Indian Priest' who 160 years later claimed to be the great-grandson of an aboriginal chief brought to France by de Gonneville; and, when, early in the eighteenth century, some geographers revived the claim in order to prove that Frenchmen were the first discoverers of New Holland, a French writer pointed out that the priest's account was full of impossibilities, and that, wherever de Gonneville went (if he went anywhere), he certainly did not reach New Holland.

Fourteen years before James Cook sighted eastern Australia, a French philosopher, Charles de Brosses, published in Paris two volumes in which he pleaded for a systematic investigation of the southern hemisphere by French navigators. De Brosses, as he acknowledged, had his attention directed to the subject by the *Petites Lettres* of Maupertuis, in which that savant enumerated 12 projects requiring to be pursued by men concerned with the advance of science—one of which was an exploration of the oceans that washed unknown lands in the south. De Brosses took up this thesis and expanded it; his copious volumes summarized all the information then obtainable about the region with which he dealt, narrated the explorations of Tasman and Dampier, and indicated advantages that might accrue to France from such a voyage as he desired to see undertaken. He also, by the by, devised the word Australasia (i.e. Asia of the south).

In 1766, ten years after the publication of the *Histoire des Navigations*, Louis de Bougainville, commanding the *Boudeuse* and the *Etoile*, sailed for the southern Pacific; his principal achievements there were the discovery of the Navigator Islands and the careful examination of the Solomons, but he did not touch the Australian continent. Five years later, in 1771, Nicholas Marion-Dufresne, with his own ship the *Mascurin* and the French warship *Marquis de Castries*, visited southern Tasmania and New Zealand, where he met his death at the hands of the Maoris in 1772. In the same year, according to some high authorities, a certain Captain de St. Alouarn in his vessel the *Gros Ventre* reached the coast of Western Australia. Doubt has been cast on the authenticity of this voyage; but Dr. A. Grandidier, secretary of the Institut de France, vouches for it, and in 1792 Dentrecasteaux (mentioned below) named after St. Alouarn the first Australian islands he saw.

The voyages of Bougainville and Marion-Dufresne were undertaken under the influence of the work of de Brosses. The next undoubted French voyage in Australasian waters was inspired by the discoveries of Cook. Louis XVI, a sincere admirer of the great English navigator, had read with keen interest the narrative of his voyage in the *Endeavour*, and resolved to fit out a French expedition to win similar renown for the navigators of France. He placed it under the command of Lapérouse, under whose name an account of the famous but disastrous voyage will be found. The mystery surrounding the fate of this brave explorer led to the despatch in 1791—just when the death of Mirabeau and the attempted flight of the royal family to Varennes were deciding the fate of the monarchy—of a search expedition under Bruni Dentrecasteaux, who in the *Recherche* and the *Espérance* visited Tasmania in April 1792, ran north to the Solomons and Moluccas and west through the Malay Archipelago, and then, turning south, sighted the coast of Western Australia in December a little south of the Leeuwin, and coasted it closely, charting it as he went, to Termination Island. Beautemps-Beaupré, the cartographer of the expedition, was a skilful draughtsman, and the excellence of his work was cordially acknowledged by Flinders when he went over the same ground ten years later. In Tasmanian waters, too, the work of Dentrecasteaux was geographically fruitful, but he failed to find any traces of Lapérouse. He himself died in distressful circumstances before the voyage was over, and Huon Kermadec, his second in command, also perished at sea. Both in Western Australia and in Tasmania, as a study of the map will show, the memory of this expedition, its commanders, and the vessels that composed it, has been well kept alive.

The most important of these French voyages, both on account of the work done and the historical surroundings, was that commanded by Nicholas Baudin (1800-4). The fact that his expedition, consisting of the *Géographe* and the *Naturaliste*, was despatched while Napoleon Bonaparte was first consul, has frequently led to the hasty conclusion that it was a subtle move in Napoleon's game of undermining British prestige. But the published and documentary material relative to the expedition gives no support to this suspicion. Baudin's diary, his despatches from Australia, and the confidential instructions given to him by the minister of marine, are sufficient to show that the expedition was scientific in its origin and purpose, and that its work throughout was pursued in a spirit of scientific research. Napoleon, indeed, had nothing to do with its actual promotion. The Institut de France was of opinion that valuable scientific work might be done by a well-equipped expedition, and prepared the plan which was ratified by Napoleon as head of the government. The whole coast of Australia from Port Jackson south-about as far as the Gulf of Carpentaria was investigated by Baudin, and the work of his cartographers, though not uniformly excellent, was often accurate and was very beautifully reproduced. This commendation chiefly applies to the charts of Spencer and St. Vincent gulfs and Kangaroo Island, where the work was in charge of Lieutenant Louis de Freycinet, a thoroughly skilful officer. The Tasmanian part of the work is also of exceptional merit. Baudin's ships visited Sydney in June-November 1802. The commander and his officers were on very friendly terms with King and the British garrison, who treated the French with generous hospitality. After their departure, on 18 November, a rumour came to King's ears that one of the officers had told Lieutenant-colonel Paterson that the expedition intended to annex territory in Tasmania for the French nation. King sent the *Cumberland* in pursuit; acting-Lieutenant Robbins, who was in command of her, finding the French at King Island, landed a party and ran up the British flag as a sign of possession. But Baudin in a letter to King denied that he had had any acquisitive purpose in view. Nevertheless the fear of French designs upon Australia had important consequences in regard to British occupation, since it led to the occupation of Tasmania and (temporarily) of Port Phillip in 1804. Baudin died before his expedition returned to France.

In 1817 Louis de Freycinet was sent out in command of the *Uranie* and the *Physicienne;* this expedition visited Australia, reaching Sydney in 1819, and produced an atlas of superb charts, which renewed French interest in Australia—and consequently renewed also British fears of a French occupation. In 1822 Duperrey, who had been Freycinet's second lieutenant, was despatched with the *Coquille* to make a thorough investigation of the Pacific: he visited Sydney in the early part of 1824, and his surgeon, Pierre Lesson, compiled a valuable history of the voyage. Before Duperrey reached France again, the Baron de Bougainville in 1824 sailed for the Pacific with the *Thétis* and the *Espérance*, and visited southern Tasmania. In 1826 Dumont d'Urville, one of Duperrey's lieutenants, took out the *Coquille* again, renaming her the *Astrolabe*, and in the next three years coasted Australia from King George's Sound to Port Jackson, and visited New Zealand and most of the island groups of the western Pacific and Malaysia. It is noticeable that he devoted particular attention to Western Port. No documentary history of these three voyages has yet been studied. They certainly corresponded with French movements in the direction of colonization elsewhere; and they had the immediate effect of inducing a British settlement at Western Port (1826) and at Albany in Western Australia (1829). Lord John Russell recorded many years later that, during his term as colonial secretary (1839-41), an official of the French government asked him how much of Australia Great Britain claimed. 'I answered "the whole," and with that answer he went away.' Whether or no the expeditions of Freycinet, Bougainville, and Dumont d'Urville were affected by some hope of establishing a French colony somewhere in Australia, it is noteworthy that after Lord John Russell's emphatic declaration French exploration came to an end.

See De Brosses, *Histoire des Navigations aux Terres Australes* (2 vols., Paris, 1756)—really an obese pamphlet; its purpose is explained above; Bougainville, *Voyage autour du Monde* (Paris, 1766-9); Rochon, *Nouveau Voyage à la Mer du Sud* (Paris, 1783); Milet-Mureau, *Voyage de la Pérouse* (Paris, 1797); Rossel, *Voyage de Dentrecasteaux* (Paris, 1808); Labillardière, *Relation du Voyage à la Recherche de la Pérouse* (Paris, 1800); Péron and Freycinet, *Voyage de Découvertes* (Paris, 1807-17); Freycinet, *Voyage autour du Monde* (1827); Bougainville, *Journal de la Navigation autour du Monde* (1824-6); Dumont d'Urville, *Voyage de la Corvette L'Astrolabe* (1830); and Lesson's *Voyage autour du Monde sur la Corvette 'La Coquille'* (1839). Ernest Scott's *Terre Napoléon* (London, 1910) treats principally of Baudin's voyage, but also discusses the whole series of French expeditions.

E.S.

Exploration by Land. Phillip, when he planted his little colony on the shores of Port Jackson in January 1788 found before him what was literally an unknown land. What lay to the westward of Port Jackson, and behind the mountains he could see on the western horizon—especially what rivers were to be found—was a question that must have risen in Phillip's mind during his first days at Sydney Cove. The food problem required an instant answer to these questions; for, if the infant settlement was to become self-supporting, land more suitable for cultivation than the rocky precincts of the Cove must be found very soon.

Phillip lost no time in commencing his explorations. In March 1788 he visited Broken Bay, a branch of which he named Pitt Water after the then prime minister. In April he explored the northern side of the harbour, and saw in the distance the range now known as the Blue Mountains; the northern part of this he named Carmarthen Hills after the Marquess of Carmarthen, the southern part Lansdowne Hills, after the Marquess of that name. But the later name, 'Blue Mountains,' was adopted very early in the colony's life, as Collins in 1793 says that the mountains were commonly known by this name 'from the appearance which land so high and distant generally wears.'

On 22 April Phillip, with 11 officers and men, set out to search for a large river which he presumed would be found at the 'rising of the mountains.' The party did not reach the river, as their provisions ran short, but saw 'a country that might be cultivated with ease.'

His most important discovery in 1789 was the river he named after Lord Hawkesbury, then president of the council of trade and

plantations; this he discovered in June when exploring Broken Bay, and in the following month explored the river (and its tributaries the Macdonald and Colo), penetrated to the junction of the Grose, and ascended Richmond Hill. Meanwhile on 26 June Watkin Tench, accompanied by Arndell (assistant surgeon of the settlement), Lowes (surgeon mate in the *Sirius*), two marines and a convict, working westwards from Rose Hill (now Parramatta), discovered a river to which Phillip gave the name Nepean, after Evan Nepean, then under-secretary to the admiralty. The Nepean is the main stream of the Hawkesbury. This river rises as the Wollondilly; receiving the Cox, it changes name to Warragamba; when the Nepean enters, the main stream takes its name until the Grose joins it; from that point it is called the Hawkesbury.

In September Botany Bay was surveyed to the extent of 30 miles, and charted by Captain Hunter. In December William Dawes, with George Johnston and Lowes, crossed the Nepean River near the present railway bridge in an attempt to reach the Carmarthen Mountains. They penetrated about 15 miles in three days, and reached a hill which they named Mount Twiss. It is difficult to locate this hill, but (judging from the plan published in Tench's *Account*) it is the high ridge beyond the present Linden railway station—the same ridge from which Blaxland, Lawson and Wentworth in 1813 took bearings of the surrounding features. An expedition led by Tench and Dawes in the following August into the district SSW. of Parramatta entangled itself in the gorges of the Warragamba—which discouraged further research in that direction. Tench gives an interesting description of the method followed by these early explorers, at any rate up to Blaxland's time:

> Our method on these expeditions was to steer by compass, noting the different courses as we proceeded, and counting the number of paces—of which 2200 on good ground were allowed to be a mile. At night, when we halted, all these courses were separately cast up, and worked by a traverse table, in the manner a ship's reckoning is kept; so that by observing this precaution we always knew exactly where we were, and how far from home—an unspeakable advantage in a new country, where one hill and one tree is so like another, that fatal wanderings would ensue without it. This arduous task was always allotted to Mr. Dawes, who from habit and superior skill performed it almost without a stop or an interruption of conversation; to any other man on such terms it would have been impracticable.

In September 1793, William Paterson, who had previous experience as a traveller in Africa, set out with George Johnston, John Palmer, and Edward Laing to explore the Blue Mountains. Boats were sent round by the Hawkesbury River to Richmond Hill; Paterson then entered the Grose River (which he so named, presumably after Lieutenant-governor Grose) and proceeded up it for 10 miles, meeting with no fewer than five waterfalls. A high peak of land, 'which they had in view in the chasm, they called Harrington's Peak.' The party had by now encountered so many obstacles that it returned, 'leaving the western mountains to be the object of discovery at some future day.' In August 1794, says Collins,

> A passage over the inland mountains which form the western boundary of the county of Cumberland being deemed practicable, Henry Hacking, a seaman (formerly quartermaster of the Sirius, but left here from the Royal Admiral), set off on the 20th of the month, with a companion or two, determined to try it. On the 27th they returned with an account of their having penetrated twenty miles further inland than any other European. Hacking reported, that on reaching the mountains, his further route lay over eighteen or nineteen ridges of high rocks; and that when he halted, determined to return, he still had in view before him the same wild and inaccessible kind of country. The summits of these rocks were of iron-stone, large fragments of which had covered the intermediate valleys, in which water of a reddish tinge was observed to stagnate in many spots. The soil midway up the ascent appeared good, and afforded shelter and food for several red kangaroos. The ground everywhere bore signs of being frequently visited by high winds; for on the sides exposed to the south and south-east it was strewed with the trunks of large trees. They saw but one native in this desolate region, and he fled from their approach, preferring the enjoyments of his rocks and woods, with liberty, to any intercourse with them. These hills appearing to extend very far to the northward and southward, an impassable barrier seemed fixed to the westward; and little hope was left of our extending cultivation beyond the limits of the county of Cumberland.

It is impossible with the meagre particulars available to identify Hacking's route. One theory is that he passed Springwood ridge, and that he was the builder of the cairn afterwards called 'Caley's Repulse' (see CALEY, GEORGE).

In June 1796, Collins records, George Bass (q.v.) and two companions made an attempt to round the mountains to the westward, but from the summit of the first ridge saw 40 or 50 miles away another range extending N. and S. At a later date Bass personally gave Péron further particulars of his attempt; they experienced, he said, 15 days of unparalleled fatigue and danger, and the space between the first and the distant range presented 'obstacles and dangers equally great with those in his rear.' It is extremely probable, judging from the rough track and the mention of some very fine land,' that Bass worked along the northern side of the Grose valley and reached Mount King George or Mount Tomah. In 1798 a proposal was made by Banks to send Mungo Park, the celebrated African explorer, out to New South Wales to explore the country, Park should be provided with a decked boat of about 30 tons in the hope of penetrating to the centre of the continent by means of some navigable river. Hunter's opinion of the proposal was 'that altho' a thorough knowledge of the interior of this country is much to be desired, the gentleman design'd to explore it, would have (I may venture to say, from my own experience) found difficultys to surmount which I fear his experience in the interior of Africa could have given but little acquaintance with.' For some reason the proposed visit of Park was abandoned. About this time a number of convicts had a peculiar delusion. The idea gained currency among them that a white civilized people inhabited the interior somewhere south-westwards of the settlement. Accordingly many of them set out for this country, which was represented as a delectable land; the fact that a few returned without finding it proved, not that it did not exist, but that they had been unlucky; and the exodus continued. At last Governor Hunter determined to send out a party, allegedly to find the happy land, incidentally to do some useful exploratory work. He entrusted the leadership to an ex-convict named Wilson, who had passed most of his time in the bush, was an expert bushman, and possessed great powers of endurance. The party left

Parramatta on 14 January 1798, but before it was much past Camden there remained only Wilson himself, one other man, and a boy named Barracks who kept an excellent diary. By following the indications of this diary along the area traversed, R. H. Cambage has ascertained that the first journey was made S. to Mittagong and then W. to the Wollondilly, while in a second—for which Henry Hacking, accompanied by Wilson and Barracks, started from Prospect on 9 March—the track taken was via Mount Jellore, Berrima and Marulan to Mount Towrang near Goulburn. These explorations, like those of Barrallier next to be related, had no practical results; but they have been detailed here because, until Cambage went to work on them, it was frequently asserted that both Wilson and Barrallier had actually crossed the main range and approached the upper Lachlan.

Barrallier (q.v.) made two expeditions into the interior. During the first, which lasted about a fortnight, he penetrated about 50 miles SW. from Richmond Hill, and claimed to have discovered a new river. The second crossed the Nepean River on 6 November 1802, and in seven weeks covered about 140 miles from Parramatta. Barrallier wrote a full report, and prepared a chart of his explorations; but it was in later years found impossible to plot the chart on a modern map. R. H. Cambage, however, by following carefully the indications given in Barrallier's geological and botanical notes, traced the explorer's approximate course, and the following memorandum is his:

In his attempt to cross the Blue Mountains in November, 1802, Ensign Francis Barrallier started from Parramatta. He passed Prospect Hill and, leaving all habitations behind, crossed the Nepean River a few miles above Camden, proceeding past a swamp called Manhangle by the natives. His course took him near Picton and thence westerly to the edge of the gorge overlooking the Nattai River, where he formed a depot, and left his bullocks and waggon. He next followed the Nattai about six miles to its junction with the Wollondilly, proceeded up the latter past the Tonalli River, crossed the Wollondilly and went westerly to the Peak Mountains at Yerranderie, attempting the ascent of the South Peak. Here he met with unfriendly natives, which resulted in his returning to his depot at Nattai. In about a week he again started with five of the strongest men and two young natives, and, passing through the gap at the north end of the South Peak, arrived at Colong Creek near the site of the Colong woolshed. Still keeping a westerly course, he journeyed through a deep passage in the mountain (since named Barrallier's Pass) coming out near the head of Bindook Swamp. After following down this swamp, and crossing Bindook Creek, his westerly course was stopped by the precipitous sides of Gulf Creek. This resulted in his turning northerly and passing over to either Waterfall or Lannigan's Creek, which eventually led him to the Kowmung River. Had he turned westerly when on the ridge between Gulf and Waterfall Creeks, he could by a fairly easy grade have reached the Great Dividing Range at Mt. Werong in a few hours.

After reaching the Kowmung, instead of following this stream upwards, he unfortunately followed it downwards to Christy's Creek, and then decided to turn westerly up this stream, at the head of which he was finally stopped by a waterfall and precipitous cliffs, at about sixteen miles in a direct line southerly from Jenolan Caves.

Being short of provisions, and finding himself in one of the roughest parts of our Blue Mountains, this heroic explorer then decided to retrace his steps.

On 11 February 1802 George Caley started from Prospect on his first journey to the 'Cowpastures.' In June of that year King reported that Caley had made several excursions into the mountains; and he made further explorations in the same district in October and December 1802, February 1804, and August 1806. His most famous exploit was his attempt to cross the Blue Mountains in a westerly direction from Prospect, undertaken in the latter part of 1804. He began at the junction of the Grose and Hawkesbury Rivers, taking the north side of the Grose. As he advanced he found the country extremely rugged and barren, and the valleys for the most part almost impassable. After incredible fatigue he reached Mount Banks on the twelfth day after he left Richmond Hill, only to find an 'inaccessible valley' in front of him. His report on returning was consequently most despondent and King summed up the result of 18 years' labours in a mournful sentence:—

As far as respects the extension of agriculture beyond the first range of mountains, that is an idea that must be given up, as the rocks to the west of that range wear the most barren and forbidding aspect, which men, animals, birds, and vegetation has ever been strangers to, a better proof of which may not be adduced than the remark of one of Caley's party in returning, who exclaimed, on seeing two solitary crows 'that they had lost their way.'

In 1812 a drought forced on Macquarie the necessity of securing fresh pastures for the colony's flocks, which were growing too big for the narrow strip between the coast-line and the Blue Mountains. In 1810 Gregory Blaxland had made two excursions up the Warragamba River, one by boat, the other on foot along the south bank of the river; and, as the result of these explorations, he evolved the theory that the range might be crossed by keeping along the watershed between the Warragamba and the Grose. With the assistance and approval of Macquarie an expedition was equipped, and Blaxland, accompanied by Lieutenant Lawson (an experienced surveyor), W C. Wentworth (then a lad), and four convicts, set out from South Creek on 11 May 1813, crossed the Nepean at Emu Island the same afternoon, and the next day began the ascent of the first ridge. Travelling sometimes two miles and occasionally five per day, the party forced its way through almost impenetrable country, always heading the gullies and clinging to the actual ridge top. Soon after commencing the ascent of the second ridge a pile of stones was found, evidently the work of Europeans; its origin is discussed elsewhere (see CALEY, GEORGE). On the 28th Blaxland, having unconsciously diverged from the central ridge, found himself at the end of a spur since called Mount York, and with great difficulty brought his horses down the precipitous sides to a well-watered valley that gave prospect of good pasture-land. Finding this sort of country to extend sufficiently 'to support the stock of the colony for the next thirty years,' the explorers returned to Sydney. They had, as a matter of fact, not crossed the main range at all; that was left for Evans to do; but they had found a way through the remarkable obstacle presented by the formation of the Blue Mountains (in which almost all the valleys are bounded by cliffs many hundred feet high, so that Blaxland's plan of following the intervening ridges was the only possible solution); and, that done, the main range had no terrors.

In 1811 George William Evans (q.v) examined Jervis Bay and found his way back to Sydney by land after encountering great hardships. On

19 November 1813 he was despatched with a party of five to continue Blaxland's explorations. Reaching Blaxland's terminal point on the 26th, he struck southwards into hilly country, but soon reached a stream (afterwards called the Fish River) which he followed W. to its junction with Campbell's River; the united stream he called the Macquarie, and followed it for another 20 miles through grassy plains into a rugged gorge; being then nearly 100 miles beyond the Blaxland point, he returned to Sydney. His news was so acceptable that Macquarie ordered William Cox (q.v.) to construct a road over the mountains along the Blaxland-Evans track, and in 1815 journeyed by this road to Bathurst (just below the Fish-Campbell junction) in nine days. On 13 May Evans, who was one of the governor's party, left Bathurst on a journey which, taking him first southwards and then west, brought him on the 25th to the Lachlan River not far from its junction with the Abercrombie. These discoveries were confirmed and amplified two years later by John Oxley, who in April 1817 followed the Lachlan from Evans's last station into vast swamps, avoided them only to encounter more swamps, and turned back just when two days' further journeying would have brought him to the Murrumbidgee; and on 6 June 1818 led another party (including Evans) down the Macquarie to yet more swamps, sent Evans on a short tour in which he discovered the Castlereagh River, and then struck NE. and E. across the Warrumbungle Ranges and the Liverpool Plains, crossed the dividing range with great difficulty near the head of the Hastings, and reached the coast at Port Macquarie.

Meanwhile the southern areas had not been altogether neglected. In 1814 Hamilton Hume and his brother John followed (unknowingly) on Wilson's tracks and opened up the Wingecarribee district, Charles Throsby in 1817 extending the settlement area beyond Sutton Forest. On 3 March 1818 Throsby and Hume,

accompanied by Meehan, started from Liverpool in the hope of discovering an overland route to Jervis Bay; finding themselves entangled in the Shoalhaven gorges near Marulan, they separated and while Throsby managed to reach the Bay via the Kangaroo and lower Shoalhaven Rivers, Hume and Meehan worked along the high land W. of the Shoalhaven, discovered Lake Bathurst, and returned to Sydney past the Goulburn plains. In 1819 Throsby linked the two districts by a journey from Moss Vale through Taralga, Burraga and Oberon to Bathurst, and in 1820 Meehan, starting almost due W. from Moss Vale, reached the Lachlan and turned northwards to Orange and Wellington. On 19 August of the same year Joseph Wild discovered Lake George, and Macquarie visited it later in the year; in April 1821 Throsby reached the Murrumbidgee somewhere in what is now federal territory, and on 1 December Robert Johnston discovered the Clyde River, from which Hume and Berry in 1822 reached Braidwood. In 1822, too, Allan Cunningham, after investigating the head-waters of the Cox and botanizing on the upper Macquarie, opened a route between Bathurst and the Cudgegong River, where William Cox and his clan were settling. About the same time settlers of less note but equal zeal were working inland from Newcastle and northwards from the Hawkesbury to the Hunter, and preparing the way for that vigorous occupation of the Hunter valley which —side by side with that of the Bathurst and Goulburn plains—characterized the later years of Brisbane's governorship. The whole territory thus explored, from the Clyde River northwards to Port Macquarie and inland as far as Meehan's line of 1820, was under Darling converted into the 'Twenty Counties' beyond which settlement was not permitted; the rest of the colony remained crown land on which adventurous 'squatters,' slowly moving farther out,

depastured herds of cattle or flocks of sheep; and it was mainly to investigate this unknown expanse for squatting purposes that the next series of explorations was taken in hand.

On 22 May 1823 Captain Mark Currie, with Brigade-major Ovens and Joseph Wild, explored the district south of Lake George, reached the Murrumbidgee, and discovered some fine country, which Currie called Brisbane Downs; fortunately this name has been replaced by the native name, Monaro. In the same year Allan Cunningham left Bathurst on 15 April with the intention of exploring the country north from the Cudgegong River as far as the Liverpool Plains. He travelled up the Cudgegong, reached the Goulburn River, crossed the Wermyse, but then, turning north, was blocked by impassable mountains. Baffled here, he turned south and then west, found and named Blaxland's River on the 21st, crossed it, and travelled west back to the Goulburn.

Although provisions were considerably reduced, and the party weak, he determined to make another attempt to discover some pass through this range, and on 2 June proceeded NNE. Twice more he was baffled and had to turn southward again, and had almost determined to leave the ranges altogether; but one more ascent was decided on, and on 5 June the party camped in a valley which he named Hawkesbury Vale. Ascending the highest ridge to the westward to make a few observations, he was gratified by seeing through a considerable depression in the main range a clear but limited view of the plains to northwards. On 7 June, following this indication, he found and traversed 'Pandora's Pass.' Peach stones were planted in Hawkesbury Vale and on the plains north of it.

Another useful exploration of 1823 was undertaken by Archibald Bell of Richmond, who pioneered the track along the northern side of the Grose valley since known as Bell's Line (see Cox, William). The value of this route—which is both shorter and less rugged than the Blaxland line—has never been understood except by stock-owners in the Mudgee district, who up to the end of the century travelled their stock along it to the coast.

On 17 October 1824 Hume, accompanied by W. H. Hovell, a free settler who had been master of a merchantman, left Hume's station near Gunning (NW. of Lake George) on an expedition towards the southern coast. Brisbane —who authorized the expedition but left the explorers to pay their own expenses—wished them to make across country to Spencer Gulf; being their own masters, they designed a route in the direction of Bass Strait. On the second day out (the 18th) they crossed fertile pastures to which they gave the name McDougall's Plains, the aboriginal name being Yarh (i.e. 'running water,' a version of 'Yarra'); Yarh has since been corrupted into Yass, and silly stories have been invented to explain the corruption. Then, plunging into the tangle of hills south-westwards, and crossing stream after stream—the Murrumbidgee, the Hume (now known as the upper Murray), the Mitta Mitta, the Ovens, the Goulburn—they made several vain attempts to penetrate the Plenty ranges, emerged at last to the west of Mount Disappointment, and maintained their south-westerly course to the shores of Corio Bay. Unfortunately at the critical moment Hovell's calculations went astray, and he fixed their terminal point exactly one degree farther east than it actually was (38° 6′ S. lat., 145° 25′ E. long., instead of 144° 25′); this mistake made them think they had reached Western Port. In after years it suited Hume to allege that he had known of the mistake all along, and had been overborne by Hovell's supposed skill in calculation; but a letter which he himself wrote to Brisbane on 24 January 1825 shows that he at that time had no doubt about the identification. This expedition had two important results. In the first place, the discovery of so many important streams, all running west or north-west, produced the impression that somewhere in the Spencer Gulf region there must be a great river-outlet for all their waters, and so led to the first of the genuinely geographical explorations (Sturt's) that are recounted below. In the second place, the mistake about Western Port deferred the colonization of Port Phillip for ten years more. For Darling, urged by the colonial office to occupy Western Port, and assured after interviews with Hume and Hovell that it was the Western Port area they had traversed, sent off a small party by sea to settle there; when reports came back that the real Western Port was unsatisfactory for agriculture, the whole enterprise was abandoned, and the current of settlement was diverted to areas far north of Sydney. For a discussion of the many legends that have collected about this Hume-Hovell expedition see Hume, Alexander and Hovell, William.

Meanwhile the trend of expansion was for the time northwards, in which direction Oxley's report of the Liverpool Plains and Cunningham's discovery of Pandora Pass led eager pastoralists to look for good pastures. Lockyer in 1825 tried to work up the Brisbane River, but found himself blocked by the ranges in which it rises. Cunningham therefore on 30 April 1827 left Segenhoe on the upper Hunter to commence the most important of all his explorations. Reaching the Liverpool Plains by a pass west of Murrurundi, he crossed the Namoi near Gunnedah on 12 May, the Gwydir near Gravesend on the 21st, and the Dumaresq (Macintyre) on the 28th, finding a succession of fertile but narrow river-valleys separated by belts of what he called 'arid desert forests.' Consequently he diverted his course from N. to NE., climbed to the level of the tableland, and on 5 June struck the Condamine River where it enters the Darling Downs. On the 8th he saw from Mount Dumaresq a vast extent of good pastoral country, and on the 11th obtained from a gap in the main range near Maryvale a view of Mount Warning to the SE. and of the Moreton Bay district to the NE. An attempt to return due S. over the tableland was frustrated by the ruggedness of the country and the severity of the winter on those high plateaux, and he eventually came back to Segenhoe by a track rather westwards of his outward route. These important discoveries he tried to develop in 1828 by approaching the Downs from the coast, at first up the Logan valley past Mount Lindesay, then up the Bremer and between Mounts Mitchell and Cordeaux. The passage, however, when found on the second attempt, was so difficult that no use was made of it; a third attempt made by Cunningham to cross the ranges more directly W. of Brisbane was a failure; and the Darling Downs were in the end occupied by squatters following in his original inland track.

The task of opening up pastoral country was from this time onwards performed by the squatters themselves as they needed room. We come,

therefore, to the third stage of Australian exploration, during which the settlement of geographical questions was the explorers' main object, and the vague belief in (*a*) a big river-outlet on the south coast and (*b*) a big inland sea receiving the waters of westward-flowing rivers from the Lachlan northwards was their chief inspiration. The first, the boldest, and by far the most unfortunate of these explorers was Charles Sturt (q.v.), whose achievements are now to be recounted.

His first expedition, in which Hume accompanied him, started in drought time from Wellington on 10 December 1828, with the objects of tracing the course of the lower Macquarie and extending the boundaries of discovery westward. On 20 December 1828 Mount Harris, close to Oxley's terminal point on the Macquarie, was reached and a depot was formed; then, while the main expedition followed the course of the Macquarie by boat, Hume was sent forward on foot with two men to pick up the river-channel some way northwards. The boat-trip, however, met with little success, as the channel was soon lost in reeds and marshes. After excursions in several directions, the party on 17 January 1829 reached New Year's Creek (now known as the Bogan River), and the next day arrived on the banks of a river to which Sturt gave the name of Darling. To the great disappointment of the explorers the water was found to be salt, but they followed it for some 66 miles before returning to the depot at Mount Harris. They next turned northwards to investigate the Castlereagh River, discovered by Evans in 1818. This was found to be dry, but its course was traced for about 100 miles towards the Darling; the forbidding aspect of the country then determined Sturt to return, and the party proceeded homewards.

The colonial government now began to think about the unexplored Murrumbidgee, and Sturt was entrusted with the command of an expedition to determine the course of this river; his party included George Macleay (see MACLEAY, ALEXANDER), and Fraser the colonial botanist. The expedition left Sydney on 3 November 1829 and reached the Murrumbidgee on the 25th near the site of Jugiong. The junction of the Tumut River was passed, and the site of Wagga, and many plains, one of which was named Hamilton, after a staff-surgeon. Sturt then attempted to connect with Oxley's farthest point on the Lachlan, and reached that river, but was unaware that he had done so. At the end of December he determined to take to the water. A whaleboat had been carried from Sydney in sections, and these were put together, while a small boat (about half the size of the whaleboat) was built on the ground by the carpenter. Six men—Clayton, Mulholland, Macnamee, Harris, Hopkinson and Fraser—were selected by Sturt to accompany him and George Macleay. On 7 January 1830 the boat-journey began, with the skiff in tow, but on the second day the skiff struck a snag and sank, and two days were spent in recovering the stores from her. For a few days their way was through reeds, but these ceased and the river ran through open country. On the 14th the boat shot out into what Sturt described as 'a broad and noble river;' this a few days later he named the Murray, after Sir George Murray, who in 1828 was secretary of state for the colonial and war department. Hume had, of course, already discovered it and named it the Hume; but Sturt considered his discovery a new stream, to which the Hume, Ovens and Goulburn all contributed. It was decided to follow the Murray River westwards, and the ensuing voyage was full of incident, especially when they encountered aboriginals; the kindly firmness of both Sturt and Macleay, however, preserved friendly relations intact. Just after the most dangerous of these encounters, on the 23rd, Sturt saw 'a new and beautiful stream, coming apparently from the north;' this, after a short journey up it, he provisionally (and correctly) identified with the Darling whose upper course he had discovered in the previous year. Then the voyage down the Murray was resumed; the Rufus (a perpetual reminder of Macleay's red hair) and the Lindesay (now, as usual, misspelt Lindsay) Rivers were discovered and named; and on 9 February Sturt saw before him a lake which he named Alexandrina, after the princess who was to become Queen Victoria. With a view of rowing to St. Vincent's Gulf —where it was possible a vessel awaited them —an endeavour was made to get the boat into Encounter Bay, but all their efforts were fruitless. A return by the route they had followed was now their only salvation. The story of this return is one of the most heroic in Australian annals. Before it began Sturt describes his crew as 'very weak from poverty of diet and from great bodily fatigue,' and calculated that the meagre ration (¾lb. flour per day) could only be maintained if they made the same speed back against the current that they had made coming down with it. But there was no other way out: on the 13th they re-entered the river, pulled up it with occasional slight assistance from the wind, reached the Murrumbidgee entrance on 17 March (26 days down, 33 back —a notable record), and six days later arrived at the depot to find it deserted. The disappointment was very nearly fatal. For another 17 days the weary and half-starved men had to pull against a flooded Murrumbidgee, uncomplaining but past any strenuous exertion; often they fell asleep at the oars; one of them became delirious. At last Sturt camped and sent two men away to bring back help from a depot at Wantabadgery, and this arrived on the very day when the last ounce of flour had been consumed. By slow degrees they made their way back to Sydney, and there Sturt went blind for many months.

In 1831 a runaway convict named George Clarke gave himself up with a story of having discovered during his absence a great river known by the natives as 'Kindur,' and a fine country to the north of the Liverpool Plains. Major T. L. Mitchell (q.v.) then surveyor-general, who had displayed great jealousy when Sturt was chosen for the 1829 expedition, now obtained leave to go exploring, and started from Sydney on 24 November 1831. Crossing the Peel and Namoi Rivers (an effort was made to sail down the last-named river in canvas boats, but snags and shoals foiled the attempt), Mitchell reached the Gwydir, turned north, and in January 1832 discovered a river called Karaula by the natives, but now known as the Macintyre. At this point his progress was stopped by the failure of his supplies, which had been intercepted and looted by blackfellows, and four years elapsed before he was again at leisure for explorations. But his earlier supersession by Sturt still rankled, and he was anxious to prove that explorer was wrong in his supposition that the Darling joined the Murray. So on 9 March 1835 he started

from Parramatta with a party that included Richard Cunningham, brother of Allan, as botanist; by 15 April he had reached the Bogan, and while here Cunningham was killed by the blacks—at any rate he wandered away from the main body, botanizing, and was never seen again. On 25 May the junction of the Darling and Bogan Rivers was reached, and to Mitchell's great delight the country was now well grassed; 15 miles down stream, therefore, he made a depot and erected a stockade, which he named Fort Bourke, and on 8 June he started down the river and followed it for some 300 miles. Mitchell was less tactful than Sturt, and a serious affray with the blacks, during which some of them were shot, marked this excursion.

Though the junction of the Darling with the Murray was now almost certain, it had not been actually demonstrated. To clear the matter up one way or the other Mitchell on 17 March 1836 left Orange in a dry season to follow Oxley's tracks down the Lachlan, which he still hoped to be the river that Sturt had mistaken for the Darling. Finding, however, that it joined the Murrumbidgee as Sturt had said, he marched across country to the Murray and along the Murray towards the Darling, made quite sure that it was the Darling, and then returned to the Murray-Murrumbidgee junction. Here he crossed the big river and proceeded along its southern bank to Swan Hill; then, striking south and south-west through a region that seemed to him—fresh from the dry Lachlan-Murray-Darling area—verdant and even paradisaical, he crossed the Avoca, the upper Avon and Wimmera (where they were still streams, not rain-water channels), and the Glenelg, which he followed partly by land, partly in a boat, to its mouth in Discovery Bay. He had started this expedition with memories of his war service in the Peninsula, and they did not leave him—his track is still marked by names such as Nivelle, Pyrenees, Arapiles, Trafalgar. From the Glenelg he marched ('marched' is the exact term for describing Mitchell's expeditions, so military were they) eastwards to strike the Hume where it had been first crossed, but was diverted to the coast again by viewing from the hills unexpectedly a settlement of white men on Portland Bay (see HENTY, EDWARD); resuming his march, he on 30 September climbed Mount Macedon and saw in the northern corner of Port Phillip 'a mass of white objects, which might have been either tents or vessels.' As Henty had preceded him in the west of Victoria, so Fawkner forestalled him eastwards. But it was Mitchell's discoveries, not Henty's or Fawkner's or Batman's, that settled Victoria during the next 15 years: squatting, not whaling or small farming, was the colonizing agent in those days.

The obviously needed connection between this new pastoral region and the just-founded colony of South Australia was supplied by the journeys of Edward Eyre (q.v.) and Joseph Hawdon in 1837. Thenceforth the main fields open to explorers were (*a*) the mysterious central region, (*b*) the vast stretch of country between the Darling Downs and the settlements in the far north of Australia, (*c*) the long coast-line, first and to this day least known of all Australian shores, between Swan River and Port Essington, (*d*) the strip along the Bight where South Australia might be linked up with Western Australia. This last exploration was undertaken by Eyre in 1840-1, and is described under his name. Chronologically the next after Mitchell's great journey was George Grey's investigation of the north-western coast at two widely separated points. In February 1838 he, with Lieutenant Lushington, made an expedition into the interior from the head of Prince Regent's River in Brunswick Bay. The most important discovery was that of the Glenelg River on 2 March; and in the ranges adjoining were found a number of extraordinary rock-paintings, which are still the subject of controversy (see ABORIGINES, under section *Decorative Art*). On 17 February 1839 Grey landed on Bernier Island in Shark Bay, discovered the mouth of the Gascoyne River, and began a boat-journey down the coast. Through a series of disasters the party had to abandon the boats at Gantheaume Bay and walk thence to the Swan River (a distance of some 300 miles); after great privations the party reached Perth in detachments.

The opening up of Gippsland by Angus McMillan and Count de Strzelecki, and the extension of pastoral occupation over the Darling Downs to the Burnett valley by Patrick Leslie and Henry Stuart Russell, are narrated under the names of the men responsible for them. More adventurous, though far less productive, was Sturt's great journey of 1844-5, instigated by the failures of Eyre (1840) and Frome (1843) to penetrate beyond the salt plains of Lake Torrens. The authorities in London suggested that he should take the line from Port Augusta northwards which Eyre had already sampled and discarded; Sturt's own choice was to evade the supposed barrier of Lake Torrens by following up the Darling to its great bend near Menindie and then striking north-west into the unknown. Great preparations were made, and the party was the largest and best equipped yet seen in Australia—12 men besides the leader, 3 carts, 200 sheep, 11 horses and 30 bullocks. Among the party were James Poole, second in command; John Harris-Browne, surgeon; and McDouall Stuart, draughtsman; and Eyre, then resident magistrate on the Murray, accompanied them as far as Lake Victoria. On 15 August 1844 the expedition left Adelaide; Laidley's Ponds (Menindie) was reached on 11 October, and Sturt decided to make for some distant ranges which Poole had seen to the north-west 'rising like islands out of a vast sheet of water.' Reaching these (the Barrier Ranges) near the present Broken Hill and travelling north along their western slopes, always lured a little farther by the discovery of some small creek or pond of fresh water that dried up almost under their eyes, the party on 12 January 1845 found near what is now Milparinka an apparently permanent creek issuing from a low range of hills, and on the 27th pitched tents beside it. Sturt considered it a convenient resting-place before his next advance. It was in fact for nearly six months his prison. Northwards no water could be found, southwards the drought had destroyed all the pools. The heat was terrific: 'the ground' Sturt wrote, 'was thoroughly heated to the depth of three or four feet . . . . under its effects every screw in our boxes had been drawn . . . . horn handles and combs were split into fine laminae. The lead dropped out of our pencils . . . . our hair as well as the sheep's wool ceased to grow, and our nails became as brittle as glass.' By May even the native birds had migrated, and the waterhole had shrunk from nine feet in depth to two. Sturt kept his men as busy as possible, surveying for 30 miles the line along which he proposed to move when the rain did

come. On 12 July a few drops fell, and by the night of the 13th it was falling steadily. Sturt had already decided to divide the party, sending most back to Adelaide so as to economize provisions for the rest; Poole, who was nominally in charge of this section, but was very ill, died almost at once and was buried under Mount Poole; Sturt with the rest of the party moved a few miles on and established a new depot at Fort Grey. After a reconnaissance westwards, which by extreme ill-luck brought up against the salt waters of Lake Blanche (thus confirming the belief that Lake Torrens extended right across the central area at this point), Sturt with four men and provisions for 15 weeks made north-west in the hope of finding a mountain range somewhere near the continent's centre. The rain had not really broken the drought; he crossed Strzelecki Creek and Cooper's Creek and the Diamantina River, hardly noticing them as creeks, but finding beyond the last-named channel that 'stony desert' which for many years was to preserve his name on Australian maps, yet is in ordinary seasons a very minor obstacle to travel. This he crossed also, and the desolate sand-hill region beyond it, and the salty spinifex ridges at the head of Eyre Creek; on 8 September he attained the point known only as lat. 24° 40′ S., long. 138° E., and thence was forced to retreat to the depot, then 443 miles away. He reached it on 2 October; on the 9th he was away again, heading due north from the crossing of Strzelecki Creek, striking Cooper's Creek where its channel was over 200 yards wide—and then meeting the stony desert once more. A second time he pushed through it, a second time was forced (on 21 October) to retrace his steps towards the depot, the water at each creek-crossing or waterhole failing before his eyes. But as soon as he reached the comparatively permanent supply of Cooper's Creek he started with renewed energy to trace it upwards towards its source. On 3 November he found its channels dispersed among grassy plains, and the natives (with whom he always kept up friendly relations) assured him that no water would be found farther east—it is in fact at this point (long. 142° E.) that the course of the creek bends sharply from north-south to east-west. By this time Sturt himself was breaking down under the long-continued hardships, and a return to the main depot became inevitable. On 13 November it was reached—and found empty, the men left there having been compelled by the failure of the water-supply to fall back on the old Rocky Glen station. Here Sturt found them on the 17th, and at once collapsed with scurvy. No rain had fallen since the July storms; the drought was earlier and worse than in the previous year; to dare another summer was certain death, to venture across 270 miles of probably waterless country to the Darling was little better. But it was better; on 6 December the party set forth (Sturt for the first time carried on one of the drays), found enough water along the route to keep them alive, and on the 20th camped by Lake Cawndilla. Still too ill to mount a horse, Sturt was brought by slow stages to the Murray and so on 19 January to Adelaide. Never before or since in Australian history has such persistent daring met with such ill-success.

Sturt's disaster checked explorations in South Australia for nearly 10 years. The scene shifts, therefore, to central Queensland, and to the less hazardous but much more profitable discoveries of Ludwig Leichhardt. This explorer, whose good fortune for a long time concealed his amateurishness, arrived in New South Wales in 1842, and for two years studied natural history in the Moreton Bay district. He hoped to be made naturalist of an expedition under Sir T. L. Mitchell, intended to open up a road from the Darling River to Port Essington, but finally determined to lead a party of his own. On 1 October 1844 he left Jimbour on the Darling Downs; passing the Condamine River, he discovered and named the Dawson River and the Comet, Planet and Zamia Creeks. On 9 January 1845 he crossed the Mackenzie River, on 13 February the Isaacs, and shortly afterwards the Suttor; but the most important discovery made in these regions was that of the Burdekin, which was followed up inland until, crossing the main watershed, Leichhardt picked up a stream flowing to the Gulf of Carpentaria, named it the Lynd, and followed it down to the Mitchell. On 28 June the party was attacked by blacks and the naturalist, Gilbert, was killed and two men wounded. From the Mitchell Leichhardt travelled along the shores of the Gulf, crossing a number of rivers, the principal of which were the Gilbert and the Roper. On 6 August the party reached a river which was identified as the Albert of Captain Stokes; but this was afterwards found by A. C. Gregory to be a mistake, and the river was named the Leichhardt. On the Roper the party lost four horses, and Leichhardt had to sacrifice the whole of his botanical collection. On 17 December the expedition, in an exhausted condition, reached Victoria on Port Essington after a journey of ten months' duration, one of the most successful Australian explorations.

Meanwhile on 15 December 1845 Mitchell, having at last obtained leave from the authorities in London, set out on his last journey of exploration to find what Leichhardt had just discovered—a route connecting the settled districts of New South Wales with its distant province in the far north. His design was to make north across country until he struck a westward-flowing stream whose outlet might be in one of the great bays of the north-western coast. Starting, therefore, from Boree near Orange, he crossed the Macquarie and Barwon, marched up the Narran, struck the Culgoa-Condamine on 1 April 1846 at a point where it is usually known as the Balonne, followed it and its tributary the Cogoon to Fitzroy Downs (9 May), worked westwards across the upper Maranoa to the head streams of the Warrego, and made north across the upper Nogoa (11 July) to the Belyando, rejecting river after river as it became evident that they were running in the wrong direction. The Belyando, which he followed for more than 200 miles, was the most misleading of all; on 8 August he had to retrace his steps towards the Warrego, and striking due west across the Nive valley suddenly found himself (15 September) on a fine stream running north-west, 'the realization' as he wrote prematurely, 'of my long-cherished hopes.' Certain that this was a headstream of the Victoria River—whose mouth lay on the north-west coast, only 1200 miles away—he bestowed that name on the infant Barcoo, which is also called in its later stages Cooper's Creek; so sure, indeed, was he that he hurried at once back to Sydney with the news; but in 1847, Kennedy, sent back to make sure of the great discovery, followed the stream past its fatal south-westerly turn to its junction with the

Thomson, blighted Mitchell's hopes, and came back down the Warrego. It is noteworthy, however, that Mitchell's journeys, futile as they might be in respect of their geographical aims, invariably opened up good pastoral country, and thus contributed to the spread of settlement in much greater measure than did those of either Sturt or Leichhardt.

After the success of his first expedition, Leichhardt had no difficulty in securing funds for a second, which had for its ambitious object the crossing of the continent from east to west. This expedition left Stephens's station on the Condamine on 10 December 1846, lost all its stock, and on 6 July 1847 was back on the Condamine, ill and half-starved; for lack of anything to do, Leichhardt then made a short excursion to the Balonne River and back. In no wise dishcartened by this abject failure, in 1848 he organized a third expedition with the same object. He could, however, obtain little satisfactory support, and for his second in command had to depend on a German brother-in-law whose sole qualification was that 'he had been at sea, had suffered shipwrecks, and was, therefore, well able to endure hardships.' The expedition started from Moreton Bay. A letter written by Leichhardt on 3 April 1848 and preserved in the Mitchell library at Sydney gives an account of the party up to that date; in 11 days they had travelled from Burrell's station on the Condamine to Macpherson's on Fitzroy Downs and everything had gone very well. This is all we know of the expedition. Not one certain relic of the party or its equipment has ever been recovered. It is practically certain that they reached the Elsey River, a tributary of the Roper; for in 1856 A. C. Gregory found there a hut which, from his characteristic manner of building one, and its relative position to the fire and water supply, was identified as one of Leichhardt's. In 1852 Hovenden Hely with a search party found two camps with trees marked L on the Nivelle River, and in 1858 Gregory discovered a tree on the Barcoo marked in the same fashion. McIntyre later found another 'L' tree and two old saddle-marked horses on a tributary of the Cloncurry. Nothing else is known of the fate or the route of the party, though various impostors (two of them prisoners hoping to procure a release) between 1857 and 1881 pretended to have either relics or news.

On 29 April 1848 E. B. Kennedy, who had been second in command of Sir Thomas Mitchell's last expedition and subsequently leader of a party of his own, set out with 12 men to find a road up the York Peninsula. The expedition was transported by sea to Rockingham Bay (about midway between Townsville and Cairns), where it landed on 30 May. Kennedy's instructions were to proceed to Port Albany on Cape York, where a schooner would meet him. From the start trouble dogged the expedition; almost impenetrable marshes, scrubs full of lawyer-vines and stinging trees, hostile blacks, and hunger beset them perpetually. On 9 November Kennedy decided to leave eight of the party in camp at Pudding Pan Hill near Weymouth Bay, while he pushed on with three men and a black boy (Jacky Jacky) to reach the waiting vessel at Cape York. Of the five Jacky Jacky was the sole survivor. A gun accident made their progress for three weeks very slow; then Kennedy decided to leave the three men near Shelburne Bay, and to push on with only the black for company. Kennedy's strength began to fail; he almost reached the end of the journey, for he caught a glimpse of Albany Island from a height; but there the blacks closed in and speared him. Jacky was wounded but dragged himself, sometimes less than a mile a day, to the vessel at Port Albany. On hearing his story the captain sailed at once, but no trace could be found of the three men at Shelburne Bay, and of the eight left at Weymouth Bay six were dead from starvation.

Apart from these large-scale explorations in eastern Australia stand a series of smaller and less hazardous, but no less useful, journeys in the areas bordering the west coast undertaken by the brothers Gregory, J. S. Roe—who in 1848-9 traversed the little-known region east of the York-Albany line—and Robert Austin, who in 1854 investigated the area between Lake Moore, Lake Austin and the Murchison.

Leichhardt was last heard of in 1848. In 1852, when he had been gone four years and should have long before made his appearance at some point on the coast, his friends equipped an expedition under Hovenden Hely to search for traces of the missing men. Blackfellows led him to various white men's camps on the Maranoa, Warrego and Nivelle, but none of these was ever satisfactorily identified with Leichhardt's journey. In 1855 the command of an expedition was given to A. C. Gregory; the design was to traverse northern Australia in a west-east direction, keeping a good look-out for traces of Leichhardt on the way. On 18 July 1855 Gregory (taking Dr. Mueller—better known afterwards as Baron von Mueller—as botanist) left Sydney in the *Monarch* and landed near the mouth of the Victoria River in Queen's Channel on 24 September. The river was thoroughly investigated until it was lost in sandy and barren country about lat. 18° S.; crossing an invisible watershed, Gregory traced Sturt Creek (as he called it) for about 300 miles SW., and was forced to turn back, as a forbidding desert stopped his advance. Returning to the lower Victoria, he arranged that a schooner belonging to the expedition should go to the mouth of the Albert River in the bight of the Gulf of Carpentaria, while he himself with Dr. Mueller and five others travelled overland. Starting on 21 June 1856, they soon struck Elsey Creek, where they found what may have been a camp of Leichhardt's; the creek led them to the Roper, which they soon left to make for the Albert rendezvous, travelling parallel to the Gulf coast but some distance inland. The Nicholson took them to the Albert, but the schooner had not arrived, and Gregory determined to proceed overland instead of by sea. A note was buried at the foot of a marked tree and on 3 September the party turned homewards, paralleling and sometimes retracing Leichhardt's first route, until they reached the eastern coast at Port Curtis. Gregory had been away 16 months, and had covered about 5000 miles. Although Leichhardt's fate was still a mystery and the new country had not proved of much value, yet the expedition was considered a great success, and in 1858 Gregory was entrusted with a second. On this occasion he used the Warrego-Nive-Barcoo route opened up by Mitchell and Kennedy, reaching the Barcoo on 17 April. He then proceeded to the Thomson, and followed it up for some distance but was turned back by the absence of grass; returned to its junction with the Barcoo and followed the latter down until it merged into Sturt's

Cooper's Creek; diverged southwards along Strzelecki's Creek, and passing between Lakes Frome and Torrens reached Adelaide. This achievement, though it added little to geographical knowledge, altered considerably the impressions of central Australia left by Sturt's drought-stricken journeys, and important results followed immediately.

Sturt, it will be remembered, had by ill-luck confirmed the impression that Lake Torrens spread in a great horseshoe so as to cut South Australia off entirely from the interior, and Gregory himself in 1856 asserted that 'the remainder of the unexplored interior is a desert, or at least unfit for the habitation of civilized man.' But the South Australians, whose western boundary at that time was the line of long. 132° E., and who wanted to extend it to coincide with that of Western Australia in 129° E., in the same year sent B. H. Babbage into the arc of the horseshoe, and he found reason for a more favourable report; the next year G. W. Goyder, the assistant-surveyor-general, extended Babbage's track to the shores of Lake Blanche (which Sturt had found so discouraging from the northern side) and found them well-grassed and well-watered; and, though his superior officer A. H. Freeling only a few months later found stony deserts and saline deposits on those same shores, private enterprise was at the same moment opening up good saltbush and grass country to the west of Lake Torrens. So, early in 1858, Babbage was commissioned to examine the new region, work up the western side of Lake Torrens as far as possible, and attempt to round its northern side and connect up with Sturt's track. As usual, his efforts were much hindered by the steady shrinkage of water-supplies, but he made two important discoveries—that well-sinking could provide ample water when the surface supply failed, and that on the western side at least of Lake Torrens the supposed water barrier was a chain of lakes, not a single stretch of water. At the same moment Gregory on the eastern side of Lake Blanche was making the same discovery; his dramatic arrival in Adelaide emphasized his announcement of it; and local discontent with Babbage's slow progress ran so high that he was superseded by Colonel Warburton (the commissioner of police), not, however, before he had in a spasm of unwonted activity penetrated to the shores of Lake Eyre South and made it probable that there was a clear break between that lake and Lake Torrens.

Two other expeditions of these years deserve notice before we take up again the story of the great explorers. In June 1857 Stephen Hart conducted a party from Streaky Bay to examine the inland areas northwards; he discovered Lake Gairdner from the western side, and reported good pastoral country towards the colony's boundary, thus strengthening the case for removing that boundary westwards. And in 1858 John McDouall Stuart, who had been restless ever since his return with Sturt, made a dash past Babbage through the Torrens-Gairdner area, struck out into the north-western unknown, enclosed the Stuart Ranges in one loop of an S-shaped track and the Warburton Ranges in the other, and reached Streaky Bay half-starved but optimistic. It was, indeed, his report as much as Gregory's that told so heavily against Babbage.

All these unexpected discoveries, breaking down almost simultaneously the pessimist theories for which Eyre's and Sturt's misfortunes and Leichhardt's disappearance were responsible, provoked a remarkable reaction at the centres of Australian enterprise. 'Philosophical' societies (as the taste of those days named what we call 'learned' societies) took up with enthusiasm projects for inland exploration. In Sydney one lecturer suggested a quasi-military expedition convoying great herds and flocks and preceded by an organized force of black trackers; another went so far as to envisage balloons. Victorians, stirred by the persistence of Dr. Mueller, who had formulated several theories during his journey with Gregory, more slowly worked themselves up into the spirit that despatched Burke and Wills. South Australia—which colony, after all, stood to profit most by the opening up of the real interior—did less as a colony than the others: its Philosophical Society had apparently exhausted its enthusiasm over Babbage, and its government was too poor to subsidize big expeditions: yet it was from South Australia, where the adventurous zeal of McDouall Stuart was backed by the private generosity of W. Finke and J. Chambers, that the first actual effort came. In 1859 Stuart merely extended the Babbage-Warburton discoveries round and beyond Lake Eyre as far as the Hanson Range; but in 1860 he launched out definitely on an attempt to traverse the continent from south to north, and on 22 April, having passed through the Macdonnell Ranges, climbed and named Central Mount Sturt (which Governor MacDonnell promptly altered to 'Stuart'). Pushing steadily on—at first west of north, then east of north—into spinifex country where hostile tribes attacked him, he was on 27 June forced to retreat; but he had already overlapped Gregory's extreme southward limit (Gregory had traced Sturt Creek to lat. 20° S., Stuart had passed lat. 19°), and his achievement received its merited reward. The government voted £2500 to equip a second expedition, with which he started at the end of the year, reaching Bonney Creek (a little short of lat. 20°) on 12 April and following its waters for some distance in the hope that it might lead to the Victoria River. When this hope failed, he returned to his earlier route due north, and managed to penetrate the scrublands for 100 miles beyond his 1860 terminus, but was again forced back; 'the plains and forest' he wrote, 'are as great a barrier as if there had been an inland sea or a wall built round.' His failure was in some degree soothed by the news that for his first journey he had been awarded the Royal Geographical Society's gold medal. Chambers and the government between them at once set to work to organize a third expedition, which started in December 1861, reached Newcastle Waters (his 1861 terminus) on 14 April 1862, and after much casting about—in the manner of hounds on a lost scent—broke through the scrub past Daly Waters to the Strangways. Down the Strangways to the Roper, up the Roper to the Chambers, up the Chambers across a 'beautiful' tableland to the head-waters of the Adelaide went Stuart and his now excited party, until on 17 July they plunged into the mud and mosquitoes of the alluvial coast-lands and on the 24th dipped their hands in sea-water at Chambers Bay, just east of the Adelaide mouth. The return trip, however, was in part disastrous; the horses died off, the natives harassed them, Stuart himself became paralysed and blind for a time; but before Adelaide was reached he had partially

recovered, and was able to enjoy the honours and rewards that were showered on him.

After all, he was not the first to cross the continent from tidal waters to tidal waters. While he was wearily retracing his steps from the first rebuff near Attack Creek, the zeal of Dr. Mueller and the generosity of the Melbourne public had sent on its way the most costly, most tragic, and least effective expedition in Australian annals. The object of the expedition was to reach the Gulf of Carpentaria via the Darling River and Cooper's Creek. £12,000 (£1000 given by Ambrose Kyte, £6000 voted by the government and £5000 subscribed by the public) was raised for it. The command was entrusted to Robert O'Hara Burke (q.v.) with the following staff:—second in command, G. J. Landells (who quarrelled with Burke before the settled districts were passed, and returned to Melbourne); astronomical and meteorological observer W. J. Wills (q.v.), who on Landell's resignation succeeded to the position of second in command; medical officer and botanist, Herman Beckler; artist, naturalist and geologist, Ludwig Becker; ten white men, and three camel-drivers (25 camels had been specially imported from India for the expedition). After a slow passage the party reached Menindie; here Burke formed a depot, left behind the greater part of his staff and equipment, and set out with six men and 15 camels to reach Cooper's Creek. The manager of a neighbouring cattle-station, William Wright, joined the expedition as third in command and guided Burke over a better route than Sturt's. On 11 November Cooper's Creek was reached, and a camp-site selected; Wright was sent back to bring up the remainder of the party, and for six weeks Burke impatiently awaited his return. At last he could restrain his impatience no longer, and determined to 'dash into the interior and cross the continent at all hazards' with the resources at his disposal. He left four men, six camels and four horses at the depot under the charge of Brahe, and on 16 December 1860 plunged into the interior with Wills, King, and Gray, six camels, one horse and 12 weeks' provisions. The party appears to have at first pursued a NW. course by way of the McKinlay Range, but soon struck a stream running almost directly northwards, and so were led to cross the Dividing Range on to the head-waters of the Cloncurry. This river led them to the Flinders, which they followed until it widened into an estuary. Burke's brief diary for 28 March 1861 says:—'At the conclusion of report it would be as well to say that we reached the sea, but we could not obtain a view of the open ocean, although we made every endeavour to do so.' Having, however, reached tidal waters, the honour of being the first to cross the continent is usually awarded to Burke and his companions. On 21 February the return journey was commenced, and on 21 April three emaciated figures staggered into the depot at Cooper's Creek—the fourth, Gray, had died on the way (according to some reports, had been killed) and was buried in the bush. Only seven hours before their arrival Brahe (who had been ordered to wait three months, and had actually waited more than four) had departed on the home journey, leaving a supply of provisions and a letter. The party, he wrote, had remained four months at the depot; Wright had not come up with the supplies; the blacks were troublesome, and the provisions exhausted. Burke, instead of following Brahe, insisted on making for Mount Hopeless, 150 miles away, relying on Cooper's Creek for water; but before leaving he buried a letter in the hole in which Brahe had left the provisions, smoothing it over, unfortunately, so that there was nothing to show that the provisions had been disturbed. Life for the unfortunate men now became a mere struggle for existence. They existed for a time on the seeds of the nardoo (q.v.), and natives occasionally gave them fish; but they had no bush-lore to teach them where ample food-supplies might be obtained—they never thought of catching fish for themselves. Wills succumbed first; Burke died two days later; King made himself useful to a native tribe, and was supported until the rescue party under Howitt reached him.

There has been, as is natural, much discussion about the causes of this tragic failure; but there is no necessity to go beyond the character of the leader. Burke was incompetent, and over-ambitious of the glory of being first across the continent. He was brave, no doubt, but other qualities are required in an explorer. He blundered in dashing off from Cooper's Creek without assuring himself that his reserves at the Darling were on the way to the Creek. He blundered in leaving his scientific staff hanging about on the fringe of the settled districts while he made a dash for glory. After his return to the Cooper's Creek depot he made three bad blunders. He could have followed Brahe's party, which was but 14 miles away on 21 April. Instead of burying the letter in the very hole Brahe had made—and smoothing the surface so that, when the latter rode back a few days later, he concluded from the absence of any signs that the explorers had not returned—he could have left some visible sign of his return. A few strokes with a tomahawk would have made the difference between life and death. He blundered most of all when, instead of making friends with the natives and copying their methods of obtaining food, he merely took what they could spare. King, who made himself useful, was given his share of the common stock. Brahe meanwhile had met Wright on the Bulloo, returned with him to the depot (where, as has been said, he noticed no signs of the explorers' return), and, growing anxious, made back to Melbourne at his best speed to urge the Royal Society to send out search parties. This, however, had been already done. Brahe met Howitt with the first on the Loddon, and returned with him to Cooper's Creek, which was reached on 8 September, and the depot on the 13th. After two days' search King was found, 'wasted to a shadow, and hardly to be distinguished as a civilized being except by the remnants of clothes on him,' but at any rate alive, and able to tell the story of the others. He guided them to Wills's grave; Burke's body was found on the 21st; Howitt buried the two decently, but on his return to Melbourne was instructed to go back again and fetch the bodies to that city, where they were given a public funeral.

When Brahe's first news reached Melbourne, arrangements were hastily made to send out three other search parties in addition to Howitt's. John McKinlay was put in charge of a party starting from Adelaide north-east; William Landsborough was directed to land at the foot of the Gulf of Carpentaria and work southwards; Frederick Walker, a superintendent of native police in Queensland, was sent in westwards from Rockhampton. It was not then known, of course, that Burke had come

back to the depot at all, and it was considered that one of the four parties must inevitably come upon his tracks towards the Gulf. In the end the journeyings of these searchers cleared up practically all the mysteries still left in eastern Australia, and by January 1863 there was no field left for exploration on a large scale east of long. 138°.

One Queensland Burke-and-Wills-relief party was under the charge of William Landsborough; it left Brisbane in the brig *Firefly* on 24 August 1861. The *Firefly* went ashore on one of Sir Charles Hardy's Islands on the way, but was refloated, and the party safely reached the mouth of the Albert in the Gulf of Carpentaria. A new river discovered by Landsborough was named the Gregory (after the explorer) and on 21 December the Herbert River was found and named—this stream has, however, been renamed the Georgina. An attempt to proceed westwards failed from lack of water; when Landsborough again on 8 February reached the depot on the Albert, he learnt that Walker had found tracks of Burke and Wills on the Flinders, and determined to make for home by that river instead of by sea. The Flinders was reached on 19 February, and the fine pastoral country through which it runs seen for the first time. Crossing to the head-waters of the Thomson, he followed that stream to the Barcoo, and on 21 May arrived at Williams's station on the Warrego. Landsborough's report led to the pastoral occupation of a large portion of the district he travelled through.

McKinlay's party left Adelaide on 16 August 1861 and on 27 September crossed Lake Torrens; from thence to Lake Hope the journey was through a dry and stony country. Leaving a depot at Lake Buchanan, McKinlay made for the Barcoo; in this region the blacks pointed out a grave, and on opening it Gray's body was found; this led McKinlay to believe other blackfellow stories of the killing and eating of white men, and to call a lake in the vicinity Lake Massacre. On his return to Lake Buchanan news reached him of the discovery of the bodies of Burke and Wills; but, as he was well supplied with provisions, he determined to continue his explorations northwards. On 17 December he set out again in a north-easterly direction, was held up by lack of water at Lake Hodgkinson (now known as Lake Apanburra, NW. of Innamincka), but on 10 February 1862 made another start, and in March crossed a large creek which he called Mueller, but which is now known as the Diamantina. The tracks of Burke were picked up in two or three places. On 6 May McKinlay reached the Leichhardt River, and on the 18th came to the tidal waters of the Gulf of Carpentaria, but the dense growth of mangroves prevented him (as it had Burke) from reaching the sea. After an unsuccessful attempt to reach the mouth of the Albert River, where a depot had been formed for the relief parties, he turned off on 21 May to reach the settled parts of Queensland through country already explored by Leichhardt and Gregory. 'To him' wrote Sir Dominick Daly to the secretary of state, 'belongs the credit of having demonstrated the practicability of driving sheep and horned cattle across the continent.'

The fourth search party was despatched from Rockhampton on 7 September 1861 under the command of Frederick Walker. On 27 September he reached the Barcoo, which he followed down for three days, finding traces of Gregory and Leichhardt; from the Barcoo he crossed to the Alice, then to the Coreena (a tributary of the Thomson), then to a river which he named the Barkly—in reality the head of the Flinders. On 25 November the junction of the Norman and Flinders was reached and the tracks of Burke and Wills discovered, and Walker then made across the Leichhardt to the Albert River depot. After a rest, he started again, followed the tracks of the unfortunate explorers to their ninth camp, and after a toilsome journey reached Strathalbyn station on the lower Burdekin on 4 April 1862. A fair area of good country was opened up by this expedition.

Before narrating the series of explorations which opened up, more or less, the western half of the continent, we may deal with two minor expeditions in the north-east. The Imperial government having decided to establish a settlement called Somerset on Cape York, at Albany Pass, John Jardine of Rockhampton was selected to command the new settlement, and arrangements were made for his two sons to take a herd of cattle overland to Somerset. Frank Jardine, the leader, was only 22 years of age; his brother Alexander was 20. The expedition started on 11 October 1864 from Carpentaria Downs station down the Einasleigh and up the eastern shore of the Gulf. Up to 13 December, when the party reached the Mitchell River, the explorers had endured a long list of troubles. Lost horses, burnt provisions, persistent and ferocious attacks by natives, united with the character of the country, make the record read like that of the ill-fated Kennedy. They crossed several rivers which they provisionally identified with those on Flinders's map—the Archer, the Coen, the Batavia—and by 17 January only 15 were left of the 42 horses with which they had started. On the 20th the two brothers started ahead to find a less difficult track to the settlement, and became entangled in the bends of a large river now known as the Jardine, which they thought was the Escape. Impenetrable country forced them to return, but on a third attempt they met with some blacks who greeted them with 'Alicko! Franko! Tobacco!' and led them to the settlement. John Jardine had taught the blacks in the vicinity of the settlement these three words, so that his sons might know they were his friends.

On 21 June of the same year Duncan McIntyre left the Paroo River with the intention of examining the country towards the Gulf of Carpentaria. Cooper's Creek was reached, and the tracks of Burke and Wills and McKinlay were followed to the north. Some 300 miles from the sea McIntyre found two old saddle-marked horses, and a short distance away the traces of two camps and two trees marked 'L;' he naturally concluded that these were relics of Leichhardt's party. On his return to the settled area interest was again aroused in the fate of the lost explorer, and a Victorian committee organized a search party, the command of which was given to McIntyre; when, however, the party reached Cooper's Creek,, the waterhole that McIntyre was trusting in was found dry, a retreat was ordered, and the expedition ended ignominiously. McIntyre subsequently reached the Gulf of Carpentaria, where he caught fever and died.

On 25 May 1861 Frank T. Gregory started from Nichol Bay on the north-western coast of Western Australia, discovered and named the Fortescue River and the Hammersley Range, and after some difficulty crossed the latter into the basin of the Ashburton. From this point the

party returned to Nichol Bay. After a rest Gregory started eastward, crossed the Sherlock and Yule Rivers, and on 26 August reached the De Grey. This river was followed for a time, and then, after crossing an immense plain, the Oakover River was found and followed up. As it bore too much to the west, Gregory left it and passed easterly through a small range to a sandy desert where he and his companions nearly lost their lives. He was forced to return to the Oakover and down it and the De Grey to Nichol Bay, which he reached on 17 October. Though thwarted beyond the Oakover, Gregory in this expedition opened up splendid pastoral country and greatly benefited the colony.

From 1864 to 1869 there was a lull in Australian exploration. The eastern colonies, in which practically all the utilizable land had been opened up (though great areas of it were still unused), were fully occupied with political problems and the extension of railways into their more closely settled districts. Western Australia, a mere patch of which was peopled, had neither funds nor energy to deal with the unknown interior; it was a crown colony, still under very definite control of the British colonial office, and had no certain prospect of owning the immense inland region, which in any case was apparently one huge desert. It was only the revival of stories about Leichhardt that induced the Western Australian government to fit out in 1869 an expedition intended to investigate one of these stories, derived from native sources. Dr. Mueller, who had stirred the government to action, was offered the command of the expedition; when he could not accept, it was entrusted to John Forrest (see FORREST, BARON). Starting from Perth, on 26 April he reached Yarraging, then the most easterly run in the colony, and on 18 May arrived at a dry salt lake (which he named Lake Barlee) near which, the story went, Leichhardt had been murdered. Finding no corroboration of the story, and being troubled by hostile blacks, Forrest determined to examine the country eastward as far as possible. With one black boy he pushed 100 miles into the desert, but all he got was a view of desolate spinifex country, open sandy plains, cliffs, and samphire flats. The party returned to Perth on 6 August.

The Western Australian government now decided to revive exploration. In 1870 it determined to despatch a party eastwards with a view of discovering a practicable route for a telegraph line to South Australia. This route had not been attempted since Eyre's journey of 1840-1. John Forrest accepted the command, and with his brother Alexander started from Perth on 30 March; the schooner *Adur* was despatched to accompany the expedition round the coast calling at various points to supply stores. Warned by Eyre's experience, Forrest kept a line somewhat inland from the bight, and so discovered that beyond the barren coastal zone there was good grazing country, deficient in permanent water. In 1871 Alexander Forrest was sent to explore the area now known as the Yilgarn and Coolgardie goldfields: he started from York on 11 August, made east for three months through barren country that seemed to him useless (little he dreamt of the gold beneath it!), turned south at a point about 100 miles east of Coolgardie and reached the coast by way of a well-grassed but badly watered region halfway between Port Esperance and Israelite Bay.

The next attempt to cross the western wastes was made from the north-south telegraph line which South Australia constructed in 1870-2 along the route originally taken by McDouall Stuart, and which obviously formed an excellent 'jumping-off place' or terminus for journeys from South to Western Australia and vice versa. In August 1872, just when the telegraph line was completed, Ernest Giles started westwards from Chambers' Pillar, was blocked by the bed of a salt lake which he named Lake Amadeus (the influence of Dr. Mueller is apparent in many of the foreign names given about this time to features of the Australian landscape), and was back at the Pillar by 18 November. The next year he started with W. H. Tietkens from Macumba, hoping to round Lake Amadeus to the south; in this he was successful, reaching the Rawlinson Range and seeing from it a line of hills—the Alfred and Marie Range—which is still merely an entry on the map; but he suffered a great deal from the hostility of the natives, and never was farther west than 125° E. Before he had even started on this journey, however, a more pretentious expedition, fitted out by two rich South Australians and provided with camels, had left Alice Springs on the telegraph line under Colonel Warburton (q.v.) on 15 April 1873 with the intention of traversing the region between the Macdonnell Ranges and Perth. In an unsuccessful attempt to reach the Sturt Creek discovered by Gregory in 1856, he got within 20 miles of it, but could not locate it. Troubles came thick and fast on the party. Eight of the 17 camels were gone, the provisions were almost exhausted, sickness crippled the men, myriads of black ants prevented sleep at night, and each day brought its struggle for water. When the party was at the last extremity, Warburton decided to abandon the attempt to reach Perth and to make for the Oakover River, at least 150 miles away. The diary of his journey across the desert to this river, which was reached on 5 December, is a record of starving and thirsting. Warburton did not expect to live through the journey, and the credit of bringing the party through is due to his companion Lewis and a native named Charley. The Oakover was followed down for some distance, but, as no signs of settlement were found, the indomitable Lewis took two camels and started in quest of assistance. The others 'waited and starved on the flesh of the last camel.' Lewis rode 170 miles to a station and on 29 December arrived back at the camp with a relief party. The wastes had been crossed; but Warburton had been too hurried to make any observations outside his actual tracks. Warburton was followed from Alice Springs on 23 April by W. C. Gosse, also in search of a transcontinental route to Perth. Gosse followed, roughly speaking, the track taken by Giles in 1872, and, like Giles, was forced to turn back by the inhospitable desert.

Warburton's dash across the northern desert had no practical results; but in 1874 John Forrest and his brother Alexander left Yuin on the Murchison (lat. 28°, long. 116°) on 13 April, followed the river to the Robinson Ranges (near the head of the Gascoyne), and then struck across waterless country SE. to the Murchison watershed, then NE to Weld Springs (where the party was attacked by blacks, and it became necessary to fire on them), then, after much casting about, SE. and E. through spinifex country, 'a barren worthless desert,' where scouting for water was the principal occu-

pation of each day. At last Forrest found himself only 100 miles from Gosse's farthest point; in front of him was the desert that had thrown back both Giles and Gosse. The conquest of this desert proved a tedious and strenuous task, but at last a providential shower of rain filled some rock-holes, and allowed the party to cross. Soon afterwards an old camp of Giles was picked up, and from here the tracks of Gosse and Giles were followed until on Sunday 27 September the overland telegraph line was reached. 'Long and continued cheers came from our little band, as they beheld at last the goal to which we have been travelling for so long.' Forrest afterwards said that the country round the Murchison was admirably suited for pastoral settlement, but he did not think the country from the head of the Murchison to the 129th meridian would ever be settled. Nor is it.

In 1875, undaunted by his previous failures, Giles was once more in the field. Thomas Elder equipped the party, which included 19 camels: but camels, however useful for crossing deserts, in some way discourage those who use them from the detailed investigation of the country passed through. A start was made from Youldah on 27 July 1875, and the party reached Perth on 10 November, after travelling a distance of 2575 miles in about five months. Giles summarized the trip as follows:—'The expedition has been successful, yet the country traversed for more than a thousand miles in a straight line was simply an undulating bed of dense scrub, except between the 125th and 127th meridians, the latitude being nearly the 30th parallel. Here an arm of the Great Southern Plain ran up and crossed our track, which though grassy was quite waterless. The waters were, indeed, few and far between throughout. On one occasion a stretch of desert was encountered in which no water was obtainable for 325 miles, which only the marvellous sustaining powers of Mr. Elder's beasts enabled us to cross. The next desert was only 180 miles to a mass of granite, where I saw natives for the first time on the expedition. They attacked us there but we managed to drive them off. Mount Churchman was now only 160 miles distant, and we found water again before reaching it.' Giles rested at Perth for two months and on 13 January 1876 started back again; this time he struck north to the Murchison, crossed to the Ashburton and, passing over 150 miles of desert, reached the Alfred and Marie Range from which the desert had thrown him back in 1873. The party reached the Peake telegraph station on 23 August 1876.

With Giles's last expedition ended the period of important explorations. Eastern Australia had been thoroughly opened up by 1863; Sturt and Stuart had laid bare the central region; Gregory had penetrated from the north as far as Sturt Creek. By the end of 1875 the western wastes had been thrice crossed—by Forrest, Giles, and Warburton—and their general character ascertained. Of minor expeditions, each filling in some small blank on the map, short notices must suffice.

In May 1876 W. O. Hodgkinson, sent to examine the pastoral country west of the Diamantina River, discovered between that river and the Herbert a stream which he named the Mulligan. This was the last expedition fitted out by the Queensland government. In 1878 Buchanan, crossing from the Queensland border to the overland telegraph line, discovered a creek (Buchanan's Creek) which afforded an important watering place between the border and the telegraph line. In 1879, a railway line between Brisbane and Port Darwin having been projected, Ernest Favenc was sent to explore the line of country. Leaving Blackall, the party reached the Diamantina, then struck NW. through unexplored country between the Burke and Herbert to Buchanan's Creek; the telegraph line was struck in January 1879 at Powell Creek station. In 1889 Favenc traced the heads of the rivers running into the Gulf of Carpentaria, and David Lindsay explored a portion of Arnhem's Land, leaving Port Darwin on 4 June and proceeding via the Katherine and the country north of the Roper to Blue Mud Bay.

The next series of journeys concerned Western Australia. On 25 February 1879 Alexander Forrest started from the De Grey River towards the overland telegraph line; he followed the coast to the Fitzroy, and that river until he struck the King Leopold Range. For six weeks he endeavoured to penetrate this range, but had to abandon the attempt, finally working round its southern end. On 24 July a fine river was discovered and named the Ord, and on 18 August the Victoria River was reached. During the next few weeks the rations were almost expended and the party suffered severely from want of water. At last Forrest rode for the line with one man; on the third day one of horses knocked up, and the line had to be reached on foot. This expedition opened up valuable country in the northern part of Western Australia.

There followed several years of great activity along the north-western coast. John Forrest in 1883-4 surveyed the area inland from King Sound. Harry Stockdale in 1884 pioneered the district near Cambridge Gulf, while surveying parties connected up the Fitzroy and Ord valleys. In 1888-9 Favenc explored the head-waters of the Gascoyne and Ashburton. In 1896 the Calvert Exploration Expedition investigated the deserts between the upper Murchison and the Fitzroy, and in the same year David Carnegie, starting from Doyle's Well (not far NW. of Leonora), traversed the wastes NNE. to Kimberley without discovering either goldfields or good pastoral country. From the South Australian side Tietkens in 1889 worked W. from Alice Springs along the tropic of Capricorn round Lake Macdonald, and David Lindsay in 1891 travelled from Gosse's 1873 terminus near the Warburton Range SW. to the Fraser Range near Norseman, and then NW. through the Coolgardie district to the Murchison. A longer and, in the end, more profitable expedition was that of F. H. Hann in 1896-8. Starting from Lawn Hill on the Gulf of Carpentaria, he made west across country to the Ord, followed that river south to Hall's Creek and, after a vain attempt to cross the desert to the head-waters of the Oakover, followed the Fitzroy down to Derby, thence visiting Broome, Condon and Roebourne. From the last-named place he tracked the Fortescue to its source, crossed the watershed to Nullagine and thence to Derby, and devoted the rest of his time to investigating the region east of the King Leopold Range, which turned out to be the valley of the upper Fitzroy and its tributaries. His latest discoveries were confirmed, and the whole area between King Sound and Cambridge Gulf traversed and roughly surveyed, by an expedition under F. S. Brockman which the Western Australian government sent out in April 1901.

Apart from the journals of the various explorers, which are numerous and often well-written, and their biographies (among which that of Charles Sturt stands out), the best authorities for the general history of Australian exploration are Favenc's *History of Australian Exploration, 1788-1888*, and Calvert's rather pretentious *Exploration of Australia* in 2 vols., which brings the story up to 1896. Among detailed studies of particular epochs may be noted, Threadgill's *South Australian Land Exploration, 1856-1880*, published by the Public Library of South Australia, which deals with primary authorities—official records, journals, sketch-maps, etc.—in a way that should be widely adopted. A shorter and more popular compendium of the main facts is Favenc's *Explorers of Australia*, published in Christchurch, New Zealand, in 1908.

Exploration by Sea. This summary of the exploration and survey of Australian waters (i.e., the coastal waters of the mainland, Tasmania, and the adjacent islands) commences with the discoveries of Captain Cook on the east coast. For earlier voyages and visits (known or supposed) of the Spaniards, Portuguese, and Dutch see AUSTRALIA, DISCOVERY OF, also PELSART, FRANCIS and DAMPIER, WILLIAM.

Cook.—For the *Endeavour* and the earlier part of his first voyage see COOK, JAMES. After observing the transit of Venus at Tahiti and circumnavigating the coast of New Zealand, Cook decided to return by way of the East Indies, making westwards until he fell in with the eastern coast of New Holland and then following it 'until we arrive at its Northern extremity; and if it should be found impracticable, then to Endeavour to fall in with the Land or Islands discovered by Quiros.' This is the reason given in his own words for the course steered, and is an effectual answer to an often-repeated assertion that his discovery of New Holland was an accident. What was known of Australasian waters on board the *Endeavour* was, briefly, that Tasman had laid down the southern point of Tasmania and the western coast of the North Island of New Zealand. The discoveries on the western coast of Australia were merely a few names on the chart. New Guinea had been discovered by the Portuguese more than 100 years earlier, but practically nothing was known of it. Torres had, of course, long before passed through the straits which bear his name, but this was not known for certain when Cook sailed; he however, believed that New Holland and New Guinea were separate islands, for he writes: 'we have now put this wholly out of dispute, but as I believe it was known before but not publicly I claim no other merit than the clearing up of a doubtful point.' At daybreak on 20 April 1770 land was sighted eight leagues away by Zachary Hicks the senior lieutenant. (This date, which differs from that given in Cook's own log, is the correct one according to modern computation. As explained under COOK, JAMES, all Cook's log-dates from 4 October 1769 to 9 October 1770 are incorrect by one day, since he had not when passing the 180th meridian of longitude made the change of date which is now customary.) The land first seen was named after the officer who sighted it. Its exact position is probably that of a hill 924 feet high now marked on the chart as Point Hicks Hill, near Sydenham Inlet. Cape Everard is close by, and it is generally accepted that this cape may be taken as Cook's starting-point on the Australian coast. A detailed discussion of the question will be found in the *Victorian Historical Magazine*, vols. ii and v. From this point Cook worked northwards along the coast, naming conspicuous landmarks or noting a description of them in his journal or logbook. Close to the Five Islands (near Wollongong) at a spot he named Red Point, an attempt was made to land, but the surf was too great; and at 2 p.m. on Sunday 29 April the *Endeavour* anchored in Botany Bay, the north head of which he named Cape Banks and the south head Point Solander. At 3 p.m. Cook, Banks, Solander and Tupia (a native of Tahiti who had volunteered to accompany the *Endeavour* to Europe) landed. A legend preserved in the Cook family states that Cook ordered the midshipman of the boat to land first. 'Jump out, Isaac' said he; so that Isaac Smith—a cousin of Mrs. Cook who survived (as Admiral Smith) to a great age—was actually the first man ashore. As the boat approached the shore, a few blacks came down, but soon ran away, except two who boldly opposed the landing. A musket was fired over their heads, and one threw a stone. A charge of small shot was then fired, to which the blacks replied with a couple of spears; a second discharge drove them off. The ship lay about half a mile from what is now known as Kurnell on the south shore, the extremes of the bay bearing E. to SE½E. During the stay of the ship a seaman, Forby Sutherland (according to the log; probably Forbes), died of consumption and was buried on 1 May at Point Sutherland. Before leaving, an inscription was cut on a tree near the watering-place giving the ship's name and the date. All traces of this tree have been lost; but two monuments at Kurnell (as the area south-east of Botany Bay is now called) are usually considered attempts to indicate the precise landing-place. One of these, a tablet put up in 1822 by the Philosophical Society of Australasia, was not so intended: indeed, the inscription on it was deliberately so worded as to avoid the claim. The second, an obelisk erected in 1870 by Thomas Holt, is contiguous to the rocks on which in all probability Cook first landed. A discussion of the whole question will be found in the *Journal* of the Royal Australian Historical Society, vol. x, pp. 240-251.

During their stay Cook, Banks, Solander and some of the principal officers of the *Endeavour* made short excursions inland, but saw nothing noteworthy—unless we may reckon as noteworthy Cook's discovery (possibly near Sans Souci at the mouth of George's River) of 'as fine meadow as ever was seen,' which Phillip's expedition 18 years later was unable to re-discover.

On 7 May Cook weighed anchor about 7 a.m. and stood out through the heads to resume his northward voyage. His official log (which, unless otherwise stated, is the particular log followed in this article) contains the following entry for noon of that day: 'The extr's of the land from N5°E. to S. b. W½W. abreast of an open bay; dist. off the nearest shore, 2 or 3 miles. Lat'd. obs., 33° 47'.' This open bay was the mouth of Port Jackson, seen between North and South Head, with Middle Head blocking it and resembling the bottom of a bay. Hawkesworth's version of Cook describes it as 'a bay or harbour in which there appeared to be a good anchorage and which I called Port Jackson.' About sunset on 7 May the *Endeavour* was off some 'broken land, like a bay, N. 48° W. Shore dist. 2½ leagues.' From this phrase the present Broken Bay—the mouth of the Hawkesbury River—takes its name. The

much-discussed problem whether or no the entry actually refers to Broken Bay is dealt with under BROKEN BAY.

On 16 May the ship was off the north head of the Tweed River, which he called Point Danger; on the 17th he saw and named Cape Morton after the Earl of Morton, president of the Royal Society in 1764-8, who took a prominent part in originating the expedition. Hawkesworth ignorantly changed the spelling to 'Moreton,' and the incorrect form has been retained. On 23 May, after rounding Breaksea Spit, a second landing was made to obtain fresh water, and someone shot a bustard of 17½ lb.; Bustard Head and Bustard Bay commemorate this landing. They now crept along the coast, lowering boats frequently to sound and explore, and sometimes anchoring for the night. From 28 May their track lay among the numerous small isles that stud the chart between 20° and 22° S., and on 4 June they entered Whitsunday Passage. On the 6th, when off what is now Townsville, they found their compass much disturbed by the nearness of Magnetic Island.

On 11 June at 11 p.m., after sounding in from 20 to 17 fathoms, the ship struck on some rocks which proved to be the edge of a coral reef a little N. of Weary Bay. She was not making much water, but was bumping hard; so in the morning Cook started 30 tons of fresh water and hove overboard some condemned stores, the iron and stone ballast, and six guns and carriages. At 10 p.m. on the 12th she was got afloat, but after midnight the leak began to gain on the pumps, and at 3 a.m. there was 45 in. of water in the hold. A sail into which hair, oakum and wool were sewn was passed under the bows and so dragged over the leak (the expedient is known as 'fothering'), and by this means one pump kept the hold free, the ship making only 15 inches in an hour. A boat was sent on to look for a likely spot to beach and repair the ship, and on 18 June she was anchored in Endeavour River, and the task of lightening her began. On the 22nd she was hauled well up the bank on the south side of the river, with her bow among the mangroves, and when the tide went down it left her nearly dry. The rock, it was found, had cut through three planks on the starboard bow and injured three others, leaving a piece wedged in the hole. On 4 July the ship was afloat again but still leaking, so they erected a staging, brought the ship alongside it and continued the repairs until 20 July; adverse winds then detained them within the bar, but after a thorough overhaul, and with a renewed stock of fresh water and some turtle, they got under way and put to sea on 6 August. During their stay natives came to the camp occasionally, but no progress was made in getting to know them. They refused the presents offered them, but were anxious to obtain turtle-meat, and when that was denied them attempted to seize it, fired the grass round the camp, and at last had to be driven off with small shot. Cook and his officers surveyed the country from the neighbouring hills and agreed that, though it looked wild, it would doubtless if inhabited yield all that man could wish for.

Their course from this time was full of difficulties, as the Barrier Reef closed in towards land, and the ship could only be navigated by continually stationing an officer at the mast-head. At last they saw what Cook hailed as an opportunity of getting outside the Barrier, and passed through 'Cook's Passage,' a little north of Lizard Island. Cook, however, was not content to leave the newly discovered coast; he wanted to know whether New Holland and New Guinea were joined. He had with him a copy of De Brosses' *Voyages*, published in 1756, which contained charts he considered tolerably good with regard to New Guinea. 'I always,' he wrote, 'understood before I had sight of this map that it was unknown whether or no New Holland was one continued land, and so it is said in the very history of voyages these maps are bound up in.' With this in his mind he stood W. again on 15 August, but on the 17th it fell calm and the ship began drifting rapidly towards the breakers; the boats were got out, and with difficulty towed her clear. 'In this truly terrible situation' wrote Cook afterwards, 'not one man ceased to do his utmost, and that with as much calmness as if no danger had been near.' A light breeze sprang up, an opening was seen, the ship steered for it, and soon passed through Providential Channel and was once more at anchor inside the Barrier. From this time onwards Cook picked his way, with the boats ahead almost all the time, until on 22 August he passed the strait between Cape York and New Guinea. Then, landing for the last time on Australian soil, he hoisted the English flag and 'at 6 possession was taken of this country in his Majesty's name and under his colours: fired several volleys of small arms on the occasion, and cheered 3 times, which was answer'd from the ship.' In the King's and the admiralty copies of Cook's journal the name is given as New South Wales, and in a letter to John Walker of Whitby (his old employer) dated 13 September 1771 Cook wrote 'The East Coast of New Holland or what I call New South Wales.' Cook had intended to land on Cape York, but a tribe of aborigines threatened to oppose the landing; to avoid bloodshed he made his landing on Possession Island, two miles off the western shore of the cape. Satisfied that he was through the straits, Cook now set all sail, but narrowly escaped running on a reef near Booby Island; at first he made for the New Guinea coast, but, taking into consideration the health of his people and the state of the ship (which was still leaking), he decided that it was not worth while to survey coasts already explored by the Dutch, and so made for Savu near Timor, where he refreshed the crew. He reached Batavia on 11 October, and England on 13 July 1771.

The officers chiefly responsible for the survey and observations under Cook were Green the astronomer and Molineaux the master. All the officers, however, took a part in the work, and Forwood the gunner and Saunders and Monkhouse, midshipmen, are mentioned as taking observations. With this help Cook compiled the *Chart of the East Coast of New Holland by James Cook 1770*, on which he wrote in more than 100 names of places. The 150 years that have elapsed since then have, of course, brought about corrections and additional details; but the accuracy of his positions (which was, no doubt, chiefly due to Cook himself and to Green) is often remarkable, especially as there was no chronometer on board the ship, and the longitude had usually to be found by lunar observations.

Cook's second voyage in command of the *Resolution* (in company with Tobias Furneaux in charge of the *Adventure*) has no great importance so far as Australia is concerned. The

ships left England on 13 June 1772 and parted company early in February 1773, after entering the Antarctic circle. Cook, having gone as far south as he considered prudent, altered his course for Tasmania, where he intended to call on his way to New Zealand, but met with a heavy gale and sea and ran before it direct to Dusky Bay in New Zealand. On 11 May the *Resolution* made Queen Charlotte Sound; here they found the *Adventure*, which had put into Adventure Bay in Tasmania, stayed there five days, and then sailed north along the coast till it trended away to the west. Furneaux, who believed that Tasmania was part of the mainland, took this westward trend to indicate a deep bay, and decided to head for the New Zealand rendezvous. Cook accepted Furneaux's opinion on this point, and went off to Tahiti to recruit and then make south again in pursuit of the main object of the voyage—the search for an Antarctic continent. The rest of the *Resolution's* voyage is outside the scope of this article except for the fact that Norfolk Island was discovered on 10 October 1774. In the end Cook, having thoroughly traversed the Southern Ocean, felt that the southern continent (if it existed) was so far south, so deep in the ice region, that further exploration would not be worth the cost and risk involved; he therefore headed for England, which he reached on 30 July 1775. He sailed again on his third and last voyage in the *Resolution* (accompanied by the *Discovery*, Charles Clerke in command) on 12 July 1776, primarily to search for land in the Indian Ocean reported by Kerguelen, then to explore such North American inlets as seemed likely to lead to the Atlantic. On 26 January 1777 the ships arrived at Adventure Bay, and on 12 February were in Queen Charlotte Sound, whence they proceeded to Tahiti. After calling at various islands they reached the Sandwich Group where the career of the illustrious navigator was ended.

The authorities for the voyage of the *Endeavour* are Cook's charts, logs (official and private) and journal, the last containing details not to be found in the bare entries of the logs. A literal transcription of the original MS. of the journal, published in 1893, was edited by Captain (afterwards Admiral Sir) W. J. L. Wharton, hydographer to the admiralty, and a marine surveyor of the highest eminence. The MS. itself, after being lost for many years, was re-discovered in 1922 and purchased by the Commonwealth in 1923, and is now in the Mitchell Library at Sydney. The journals of Banks and Parkinson give useful additional details. The first volume of the *Historical Records of New South Wales* contains extracts from Cook's logs, and from journals kept by officers on the ship. Kitson's *Life of Cook* (Murray, London, 1911) gives a short and fairly accurate summary of Cook's work, and it has been excellently summarized in Wood's *Discovery of Australia*, cc. xxii-xxiv. Besides these there are a great number of 'Lives' of Cook in which the authors achieve remarkable success in avoiding the task of telling what Cook did.

Phillip, etc.—Phillip in his instructions was directed to use the *Sirius* and the *Supply* when possible to explore 'the several ports or harbours upon the coast, and the islands contiguous thereto, within the limits of your government.' As the King's commission gave him authority over a territory extending from Cape York to the South Cape of Tasmania and over all islands in the Pacific Ocean within the latitudes of those capes, the limits of his exploration were confined, practically, to such parts of it as had already been discovered by Captain Cook; eastwards, however, he had great scope. The survey of Port Jackson was begun by Hunter early in February 1788 and went on as often as opportunity offered until Hunter sailed for the Cape of Good Hope in October; it was revived soon after he returned on 9 May 1789. The survey of Broken Bay and Botany Bay was also carried on, Phillip himself taking an active part. The charts thus made were so accurate and detailed as to be sufficient for all practical purposes until Sydney became one of the principal seaports of the world, and the increase in the size of ships made extreme accuracy necessary. Phillip had no opportunity of examining the coast, as the ships were required for more important work; the survey of the harbour and bays was begun with boats, and one or two handy schooners were acquired later. Phillip's other explorations are enumerated under EXPLORATION BY LAND; but it should be noted that the sea was his main highway, and many of his expeditions started in boats from bases at Manly or at Botany Bay. The discovery of Lord Howe Island and the settlement at Norfolk Island are recounted under the names of those islands.

The *Francis*, a schooner-rigged vessel of 41 tons which had been sent out in frame from England, was launched on 24 July 1793—the first vessel launched in Australia—and did good service in coastal exploration. Some of the transports, too, added a little to the knowledge of the coast-line, especially those that were temporarily equipped as whalers (see WHALING) after landing their human cargo. The brig *Mercury* in 1789 visited and named Cox Bight in southern Tasmania and Oyster Bay on the inner side of Maria Island. In 1791 (a year prolific in this kind of discovery) the *Atlantic*, a transport in which Lieutenant Richard Bowen (see BOWEN, JOHN) was naval agent, put into Jervis Bay in August, and Bowen named the bay after Sir John Jervis (afterwards Lord St. Vincent) under whom he had seen active service; he also made a rough chart of the bay. In November the *Matilda* put into the same bay to stop a leak, and her master made an 'eye-sketch' of it. In December the *Salamander* put into Port Stephens, and her master made a similar sketch of the port and some of its branches.

On 21 August 1788 Bligh in command of the *Bounty* called in at Adventure Bay on the east coast of Tasmania, which he had previously visited when in the *Resolution* under Cook. Early in May 1789, during his famous boat-voyage after the mutiny aboard the *Bounty*, he noted several islands and bays and refreshed his crew with booby-birds on Cook's Booby Island, west of Cape York. Edwards in the *Pandora* was wrecked on a reef at the entrance to Torres Straits on 28 August 1791; and Bligh in the *Providence* (with Portlock in the *Assistant*) made the passage of the straits on his second voyage in 1793. The chart is strewn with names commemorative of these vessels and voyagers.

Lieutenant John McCluer—a distinguished surveying officer in the East India Company's service whose charts of the eastern coast of India remained practically unaltered for nearly half a century—on 16 July 1791 in the *Panther* (with Proctor in the *Endeavour*) started a survey of the northern coast of New Guinea which lasted two months; an important inlet which he discovered still bears his name.

Lieutenant John Hayes (q.v.) in 1793 sailed

from Calcutta to open up trade with New Guinea, but found it necessary to take the route round Australia, and on his way visited southern Tasmanian waters; the French admiral, Bruni D'Entrecasteaux, had during the previous year visited this coast and surveyed the channel which still bears his name (see EXPLORATION, FRENCH). Hayes in April-June 1793 thoroughly examined the Derwent estuary, and then proceeded to visit the SE. and N. coasts of New Guinea as well as several island groups in the near Pacific. On her passage to England the vessel carrying his charts and journal was captured by a French warship, and the documents are believed to be at the present time housed in some French public institution.

Bryant's party (see BRYANT, WILLIAM) in their boat-voyage of 1791 along the eastern coast entered a fine harbour said by them to be in 30° S.—which was, however, probably Port Macquarie (31°26′) discovered by Oxley in 1818.

In September 1797 the *Cumberland* was on her way to the Hawkesbury when she was seized by a part of the crew; the coxswain and three others, who would not take part in the seizure, were landed at Pittwater, proceeded overland to Port Jackson and gave information. Lieutenant T. G. Shortland of the *Reliance* was sent after the escapees in a good whaleboat; he found no traces of them in Port Stephens, but on his return entered a river about 10 leagues SW. of Port Stephens, on whose shores he found a considerable quantity of good coal lying so near the waterside as to be conveniently shipped. This was, of course, the estuary of the Hunter.

The *Sydney Cove*, from Calcutta to Port Jackson, was wrecked on Preservation Island (one of the Furneaux Group) on 8 February 1797; 17 of her crew, many of whom were lascars, embarked in the long-boat and attempted to reach the mainland; the boat was capsized near Cape Everard, but her crew landed and travelled along the coast in the hope of reaching Sydney. The party (two officers, three white seamen and 12 lascars) began its journey on 15 March, and on 15 May reached Coalcliff, about 14 miles S. of Botany Bay; here the smoke of a coal fire they had made attracted the attention of the settlement fishing-boat, and three survivors were picked up and brought to Sydney. Hunter despatched the *Francis* schooner and the sloop-rigged boat *Eliza* to the rescue of those who had been left on Preservation Island; what cargo could be salved was taken on board, six of the shipwrecked crew volunteered to remain behind in charge of the rest, and the *Francis* and *Eliza* sailed for Sydney on 21 June, the *Francis* arriving after a stormy passage 15 days later, while the *Eliza*, which had separated from her consort soon after leaving Preservation Island, was never afterwards heard of. In August 1797 George Bass (q.v.) was despatched in a whaleboat to Coalcliff, and there found the skeletons of some of the castaways, who had died of exhaustion before their comrades were rescued. About 21 miles from the south head of Botany Bay he discovered good coal,—but difficult of access, he reported, unless a good harbour could be found near it. So began our knowledge of the Illawarra coal-field.

In September 1791 Vancouver in H.M.S. *Discovery* (with Broughton in the *Chatham*), after rounding the Cape of Good Hope on his way to take over Nootka Sound from the Spaniards and survey the North American west coast, discovered and named King George's Sound in Western Australia. The Middleton Reef and adjacent banks were reported from time to time by transports and whalers bound north; the Middleton was first seen by J. Shortland in the *Alexander* in 1788, and the *Supply* in 1798 was sent specially to fix its position. The whaler *Chesterfield* and the storeship *Shah Hormuzear* in 1793 attempted some exploration in boats in Torres Straits and along the Barrier Reef, so that they were six months on the voyage to Timor. On 29 June natives attacked one of the boats, killing four of the seamen and wounding others. Two Spanish ships on a voyage of discovery, the *Descubierta* and the *Atrevida*, arrived in Port Jackson on 13 March 1793 and remained until 12 April. They coasted New Guinea and New Zealand, but added nothing of importance to the charts of Australasian waters.

The authorities for this period are Collins, Hunter, Phillip, and Tench, who took part in the work; the charts made by the explorers themselves; and the various editions of sailing directions in and near the time. Contemporary books and periodicals relating to naval subjects have many references to the work, and there is much other miscellaneous literature on the subject. The manuscript journal of William Bradley, 1st lieutenant in the *Sirius*, which is in the Mitchell Library at Sydney, is of primary importance as regards the years 1788-91. Besides the text, it contains views in water-colour of Broken Bay and its branches, and charts of Port Jackson as far as Rose Hill, Broken Bay up to the entrance of Berowra Creek, George's River to Salt-pan Creek, and Norfolk Island.

Bass and Flinders.—When on 25 September 1795 H.M.S. *Reliance* entered Port Jackson, she carried among her officers George Bass as surgeon and Matthew Flinders as one of the midshipmen. A month after their arrival these two began a famous and important series of explorations. Bass had brought out on the deck of the *Reliance* a boat eight feet long, which he called *Tom Thumb*; in this the friends explored Botany Bay with such success that they had another boat built, not much bigger, and in March 1796 set out in it southwards along the coast in search of a rivermouth supposed to lie not far away. During the night of 25 March the Notonectian current carried them beyond Bulli, and a head wind prevented their return; they were therefore compelled to run for the Five Islands (close to Cook's Red Point), near which they were fairly washed ashore by the surf, and their stores thoroughly wetted. Some blacks whom they encountered were inclined to be aggressive; Flinders, to divert them, produced a pair of scissors and persuaded them to have their hair and beards cut, while Bass dried the stores and made the boat ready to resume the voyage. On their way back they encountered bad weather, had all they could do to keep the boat from broaching to, and were glad to make Providential Cove, now known as Wattamolla (Flinders says the native name was Watta Mowlee). On 1 April they examined Port Hacking, previously discovered by and named after Henry Hacking the Sydney pilot; and on the evening of the following day the *Tom Thumb* was secured alongside the *Reliance* in Port Jackson. In June 1796 Bass diverted his energy to an attack on the Blue Mountains, described under EXPLORATION BY LAND. In August 1797 he was sent in a whaleboat to Coalcliff, as already narrated. The news he picked up from the survivors of the *Sydney Cove's* crew led him to ask Hunter for a good boat manned by six seamen

wherewith to investigate the region in which that vessel had been wrecked. Flinders, who had just been promoted lieutenant, was busy on repairs of which the *Reliance* stood greatly in need, so Bass on this occasion went alone. 'On Sunday Dec. 3, 1797 at 6 p.m.' he wrote in his journal, 'we towed out between the Heads. At night we anchored at Little Harbour, for the night looked squally and uncertain and things had not yet found their proper places in the boat.' On 7 December he was near Jervis Bay, where he discovered and named the Shoalhaven; on the 14th in Bateman Bay; on the 19th in Twofold Bay; and on the 20th off Cape Howe. On 1 January 1798 he was in the vicinity of Cook's Point Hicks (which he did not see), and the next day rounded Wilson's Promontory, intending to make Furneaux Islands, replenish his water and obtain mutton-birds for food. But the wind was from the SW., and the boat leaked; he was driven to the westward, and so discovered and entered Western Port. On the return he spent some time examining Wilson's Promontory, and from what he saw came to the conclusion that:—'Whenever it shall be decided that the opening between this and Van Diemen's Land is a strait this rapidity of tide and the long south-west swell that seems to be continually rolling in upon the coast to the westward will then be accounted for.' He arrived in Sydney on 25 February 1798. The whaleboat was preserved for some time; Péron, writing in 1802, says that it was treated with 'religious respect;' but the picture given of it in his Atlas is certainly not a whaleboat—someone may have played a practical joke on him. When the boat fell to pieces, its timbers were made into snuff-boxes and similar curios.

Flinders meanwhile had gone with the *Francis* on her second voyage to the wreck of the *Sydney Cove* (see previous section), and the information he gathered there about the westward-setting tides strengthened his belief that a passage was open in that direction. Talks with Bass confirmed the belief; Hunter was willing to back it; six months later the *Norfolk* (a sloop of 25 tons that had been built at Norfolk Island) was fitted out, and with a crew of eight men Bass and Flinders started on 7 October 1798 to settle the question. They passed Green Cape two days after leaving Sydney, and then made for Twofold Bay, which they surveyed between 9 and 14 October, and reported it as useful for a whaling station. Past Cape Barren Island they sailed through Banks' Strait, and proceeded along the north coast of Tasmania, discovering Port Dalrymple on 3 November. On 3 December they left this port westwards, and on the 8th rounded a headland and saw a swell from the south-west breaking heavily on a reef. This was final: they had passed a strait and come back into open ocean. Rapidly—for the western coast of Tasmania struck Flinders as 'dismal' and 'horrible'—they ran down to South-west Cape, entered the estuary of the Derwent on 21 December, spent ten days in investigating it, and on the 31st set sail again for Sydney, which was reached on 12 January.

On 8 July 1799 Flinders in the *Norfolk* went off to explore Cook's Glasshouse and Hervey Bays (Bass had gone to England). On this voyage Flinders named Shoal Bay, added five islets to Cook's Solitary Group, and named Sugar Loaf Point, Pumice Stone River, and Point Skirmish (after a slight affray with the blacks); also, following Hawkesworth's narrative instead of Cook's chart, he altered the spelling of Morton Island to 'Moreton.' He returned to Sydney on 20 August.

The authorities for this section are the charts for the period, the contemporary narrative in Collins's *Account of New South Wales*, the logs of the boat-voyage and of that in the *Norfolk*, and Flinders's own *Voyage to Terra Australis* with its accompanying atlas. Ernest Scott's *Life of Matthew Flinders* covers the ground very fully, and is well documented.

Grant and the 'Lady Nelson.'—Captain John Schanck, R.N., one of the commissioners of the transport board, who during the American war had given evidence of his skill in constructing small vessels for service on the lakes, in or before 1783 invented sliding keels (centre-boards) and in 1789 demonstrated their utility in the cutter *Trial*. It was then determined that a 60-ton brig, the *Lady Nelson*, should be constructed to test still further the value of the invention. This vessel was in 1799 assigned for work on the Australian coast, and on 16 January 1800 left the Thames in command of Lieutenant James Grant. On her way out she met with bad weather, but behaved well, thoroughly demonstrating that her sliding keel (which was constructed in three parts) did not interfere with her seaworthiness. The brig called at Santiago in Cape Verde group and at Cape Town in South Africa, where Grant received a letter from the Duke of Portland instructing him to make for Sydney via the newly discovered Bass Strait. On 3 December 1800 Grant made his landfall on the South Australian coast, naming on that day two mountains (Schanck and Gambier) and two capes (Northumberland and Banks). Thence he made a careful examination of the coast-line as the *Lady Nelson*—the first vessel to do so from the west—passed through the strait (crossing almost directly from Cape Otway to Wilson's Promontory), and arrived in Sydney on 16 December. On 6 March 1801 King sent the *Lady Nelson* to make a further survey of the bight near Western Port which he had previously left uninvestigated. The *Bee* (a local vessel of about 15 tons, manned by convicts) was ordered to accompany the *Lady Nelson* as a tender; but she was so unseaworthy, and her master and crew so unskilful, that Grant when off Jervis Bay sent her back to Sydney. Francis Barrallier—afterwards well known in land exploration—and George Caley the botanist accompanied Grant, who remained in Jervis Bay from 11 to 13 March, surveying it in boats, and then proceeded to Bass Strait, coasted along from the Promontory to Western Port, stayed there surveying from 21 March to 29 April, and returned to Sydney on 14 May 1801. The *Lady Nelson* was now ordered to convey Lieutenant-colonel Paterson to the Hunter to make a survey there. The *Francis* was to accompany Grant and bring back a cargo of coals; and Dr. Harris, Barrallier, and Lewin the artist were to assist in the survey. On 12 June Grant rounded Nobby's, and on the 26th sent back the *Francis*, loaded with 40 tons of coal and plenty of wood. Grant, Paterson, Barrallier and Harris meanwhile examined the neighbouring country. On the 28th the ship was taken six miles upstream, and the party spent more than three weeks in boat-voyages up various rivers. It is noteworthy that Barrallier considered the main stream to run due N. and S.—on his map what is now the Hunter is treated as a tributary and called the Paterson, while the name 'Hunter' is given to the Williams. On 22 July the *Lady*

Nelson sailed for Sydney, where Grant handed her over to the colonial government and decided to return to Europe.

Grant was succeeded by Lieutenant John Murray, who had been master's mate of the *Porpoise* and acting first mate of the *Lady Nelson* on her trip to Western Port. After a voyage to Norfolk Island he was sent by King (who had never been satisfied with Grant's doings in Bass Strait) to 'prosecute discoveries in those straights on the southwest coast of this country.' His instructions were exceptionally precise: King was determined to have things properly done this time. He was to go first to the Kent group, then to Wilson's Promontory, then to Point Schanck (which seems to have been the western limit of Grant's view), and then to 'trace the coast between Point Schanck and Cape Albany Otway.' King Island must next be investigated, the western end of the strait charted, and the coast west of the Otway examined as far as Cape Banks. Murray left Sydney on 12 November 1801, and began badly by mistaking the Furneaux group for the Kent group, but retrieved his error and by 7 December was in Western Port. Leaving this harbour on 4 January, he ran west along a coast-line obscured by bush fires, but about 3 p.m. 'saw ahead an opening in the land that had the appearance of a good harbour NW. 10 or 12 miles'—the first authenticated sight of Port Phillip by a white man. Fearful of being driven on a lee shore, he stood away towards the Otway, ran down to King Island, spent the rest of January making a careful survey of it, and on the 30th, while trying to reach the Otway again, was driven back to Western Port. On the 31st he sent off the ship's launch under Bowen to look at the new harbour westwards; it returned on the 4th with the news that the entrance was good, about 1½ miles across, that within it was '*a most noble sheet of water*,' and that the boat's crew had lived on swans all the time they were away. On the 14th, therefore, Murray took the *Lady Nelson* in through the heads and anchored somewhere near Sorrento. His enthusiasm about the beauty of the shore led him to compare it first to Greenwich Park, then to Blackheath; 'the hills and valleys' he wrote in his log, 'rise and fall with inexpressible elegance.' No wonder Collins a year or two later was disappointed with the actual country. On the 16th the crew had a brush with the natives; no harm was done, but the natives were scared away, and no information was procured from them. On the 21st the launch discovered and explored Corio Bay: on 5 March the South Channel was found after much hunting: on the 8th at 8 a.m. Murray hoisted the Union Jack on shore and at 1 p.m. took formal possession of the country for England. On the 11th he passed the heads outwards in 'such a ripple that we expected every minute it would break on board'—the first mention of the Rip—and on the afternoon of the 23rd was back in Port Jackson.

The original authorities for this period are the logbooks of Grant and Murray, and the charts of the latter officer preserved in the admiralty's library. These documents have been fully used and are largely quoted by Ida Lee in her *Logbooks of the 'Lady Nelson.'* Grant's *Narrative* of the ship's voyages while under his command is also worth study.

Flinders.—When the *Reliance* reached England, the charts of the discoveries mentioned under *Bass and Flinders* above were published, and a plan was proposed by Sir Joseph Banks for completing the examination of the Australian coast. The *Xenophon*, a sloop of 334 tons, was chosen for the work; her name was changed to *Investigator*, and Flinders, promoted commander on 25 January 1801, was given charge of her on 16 February. He was supplied with a long letter of 'Instructions' and a passport in French setting forth the peaceful mission of his ship, in case he should fall in with French warships. Among the ship's company were John Crossley (astronomer), Robert Brown (naturalist), Ferdinand Bauer (natural history painter), and William Westall (landscape painter). Crossley left the ship at the Cape of Good Hope on account of illness, and Flinders, his brother Samuel (the second lieutenant), and John Thistle the master were principally responsible for the scientific work. On 6 December 1801 the ship was off the Leeuwin, and Flinders began a thorough survey from that point onwards, of a coast-line only before known imperfectly by the vague discoveries of Nuyts, Vancouver, and D'Entrecasteaux. Grant in the *Lady Nelson* had discovered a part of it in 1800 on his way to Port Jackson, but of this Flinders was unaware when he was on the coast.

On the 7th Flinders fixed the position of the Leeuwin, and from the 8th to 5 January 1802 was in King George's Sound. He next passed through the Recherche Archipelago, sighting 45 islands in the group. Eight years earlier D'Entrecasteaux had been in these waters, and to that navigator Flinders gave full credit for his discoveries, leaving unaltered names that he had given, though often correcting their positions. The Frenchmen had stood away after passing the islands of St. Peter and St. Francis at the extremity of Nuyts' Land, and from there Flinders was on a practically unknown coast-line. On the night of 26 January he crossed the meridian that now forms the western boundary of South Australia, and work in Nuyts' Archipelago, the Investigator group, and along the coast as far as Cape Catastrophe, filled the period from that date till 20 February. On the night of 21 February John Thistle was drowned; he had been with Flinders in the *Norfolk*, and before that with Bass in the whaleboat, and his loss was deeply felt by his commander. The *Investigator* was now just within Spencer Gulf, where—because of an unusually strong tide-set from the north, whither also the lie of the land was—Flinders hoped to find some passage through to the Arafura Sea. After a thorough survey of Port Lincoln he on 6 March started hopefully up the gulf; but it narrowed and shoaled steadily, and on the 11th he took to a boat, made sure that there was nothing north of him but mangrove swamps, and reluctantly gave up his illusion. Working slowly down the eastern coast, he passed Cape Spencer on the 20th, coasted along Kangaroo Island to the eastern side of Nepean Bay, worked back and forth across Investigator Strait and up into St. Vincent Gulf (the head of which he reached in a boat on the 30th), came back to Nepean Bay—where he was greatly interested in the abundant fauna, emus, kangaroos, pelicans, seals—and on 7 April traversed Backstairs Passage to meet next day a strange sail. He knew before he left England that the French government had sent an exploring expedition to Australian waters, and surmised rightly that this was one of their vessels; it was, in fact, Baudin's *Le Géographe*, whose story will be found under EXPLORATION, FRENCH. After friendly conversations the two explorers parted

company, and Flinders on the 27th passed Cape Banks. At this point we may note his extreme punctiliousness in the matter of nomenclature. He bestowed names freely wherever he believed himself the first discoverer; where anyone had preceded him, he insisted on the retention of the first-given name, were it Dutch or French or English. Thus from the Leeuwin to Encounter Bay (where he met Baudin) all the names are his own except what few the Dutch had given long before and two patches of French names —one near the Leeuwin itself, the other on Kangaroo Island—that were rightfully D'Entrecasteaux's or Baudin's. From the Bay to Cape Banks also Baudin was undoubtedly first, and his names remain on the map to-day; east of Cape Banks—where Baudin scattered French names profusely, naming the whole country from Wilson's Promontory to Streaky Bay 'Terre Napoléon,' just as he complacently renamed the very gulfs from which Flinders had just come —Flinders abode by the nomenclature of Grant and Murray and Bass, adding a few names of his own, but never altering those already given. The fact that a few of Murray's names in Port Phillip were replaced by those of Flinders is due to the fact that Murray's charts were lost for many years.

On 21 April Flinders found himself under the lee of King Island, and on the 26th ran across to Cape Schanck and bore up towards the entrance of Port Phillip, which he at first took for Western Port. Next day he discovered his mistake, and began to examine the country; but the mass of shallows that lies just inside the mouth of the bay, and is now evaded by keeping well along the southern shore, puzzled and hindered him, and (except for a visit to Station Peak beyond Corio Bay) he did little but unconsciously duplicate Murray's work. On 3 May he left the bay, and on 9 May was in Port Jackson. On 21 July he sailed again, in company with Murray in the *Lady Nelson*, to make a more careful examination of the coastline Cook had charted, and to survey Torres Straits and the western side of the Cape York peninsula. Against the skill of Flinders Murray's zealous amateurishness showed badly, and on 18 October he was sent back to Sydney. Meanwhile they had discovered the two best harbours on the north-eastern coast, Port Curtis and Port Bowen (now known as Port Denison, with the town of Bowen on it). Soon after the last of these discoveries Flinders threaded his way through the Barrier Reef by Flinders Passage, the most southerly of those now used, and on 28 October was in the mouth of Torres Straits. On 3 November he entered the Gulf of Carpentaria, careened his ship, and to his great disappointment found her in very bad condition; she was quite unfit to stand a storm, but with continued fine weather might last six months. This made return through the straits too dangerous to be contemplated, and Flinders determined to continue his work in the Gulf, where mild weather might be expected, and then to run for Sydney clean round Australia with possibly following winds. On the eastern side of the Gulf he identified as well as he could (but unfortunately with many inaccuracies) the rivers laid down from Carstensz's survey on Tasman's chart; along the western side he put in three months of assiduous investigation; and on 18 February, when among the English Company's Islands off the NE. corner of Arnhem Land, fell in with a flotilla of praus from Macassar that were searching for bêche-de-mer, and gave them the first news the Malay princes ever received of the occupation of Australia by the English. Then, making hastily for Koepang in Timor to make what minor repairs he could, he left again on 12 April and ran west-about past the Leeuwin to Port Jackson, which he reached on 9 June after an absence of 10 months and 19 days. The *Investigator* never explored again. Used as a storeship in Port Jackson till 1805, she was thought sound enough in that year to make the voyage to England; but, when she at last reached Plymouth in a 'deplorably crazy' state, she was condemned at once and in 1810 broken up.

Flinders, however, was not to be put off his life's work by a ship's unseaworthiness. King offered him any of the vessels lying in the harbour, but none was sound enough for rough usage. It was finally decided that the *Porpoise* should be sent to England 'by the route Captain Flinders may indicate,' so that, without incurring the great expense of fitting up a doubtful vessel for special work, Flinders might carry out some explorations on the way home and then return to Australia in a seaworthy ship. The *Porpoise* left Port Jackson on 10 August 1803, taking by Flinders's orders the route via Torres Straits; on the 17th she went ashore on Wreck Reef, which lies in open ocean about 740 miles NNE. of Sydney. Two merchant vessels were with her; one was wrecked a little way off, the other deliberately deserted the wrecked ships and went on to Batavia and India—and on her way from India to England disappeared, and was never heard of again. Flinders made a camp on the reef, organized the refugees, and on the 26th started back to Sydney in a ship's cutter, regaining Port Jackson on 8 September —no mean feat of navigation. Just six weeks from the day he left he was back again with three rescue vessels—one, the old *Francis*, to take to Sydney those who wished to return there; one, the *Rolla*, bound for China (in her went the younger Flinders and John Franklin); one, the *Cumberland*, a 29-ton schooner that had been built some years earlier in Australia, to take Flinders himself and ten picked men to England as directly as possible. This vessel was leaky and deficient in storage-room, so that Flinders was compelled to put into port oftener than he wished. He filled up and did some repairs at Koepang, and then tried to make the Cape of Good Hope direct, but met a heavy swell 23 days out, took in more water than he dared neglect (he had only one pump in working order), and was forced to run for the Mauritius. This was possibly an enemy colony; he had left England in peace-time, but everyone knew then that war was imminent; the *Investigator*, however, like most vessels engaged in scientific expeditions at that time, had a passport ensuring her safety from hostile attack, and Flinders trusted that his would serve for any peaceful vessel that he might command. On 15 December 1803 he entered a small port in the south-west of the island; he left it on 13 June 1810. The full story of his captivity, and the reasons—some of them mere misunderstanding, some of real weight in wartime—which induced Decaen, governor of the Mauritius, to detain a peaceful explorer engaged in purely scientific work, are set forth in great detail in Scott's *Life of Matthew Flinders*, and may be studied there; suffice it to say here that the detention was not the mere brutal act of tyranny that is so often depicted, and that the charge (even more frequently made) that advantage was taken of

Flinders's position to steal his charts and publish them in Paris as showing French discoveries has been completely disproved.

Set free in June 1810 and given a passage via the Cape to England, Flinders reached London on 23 October and at once set to work to prepare his charts and logs for publication. One evil his long detention had wrought; it had given Péron and Freycinet, the geographers of Baudin's expedition, a chance of publishing their results first; and, as they had skirted the same coasts between Bass Strait and the Leeuwin, and had (as already mentioned) renamed every feature they noted without the slightest regard for the work of previous explorers, the prior publication of their book and atlas both irritated and injured Flinders. He worked incessantly and with extreme care, in spite of the recurrence of a constitutional trouble which aged him so that at 39 he looked like 70. On 18 July 1814 the first copy of *A Voyage to Terra Australis* was sent to his house, but he was already unconscious; on the 19th he died.

The story of his detention, release, later work and death does not properly belong to the records of exploration. But Flinders was too great and too unfortunate to be left at a loose end; his story had to be completed when once begun.

Phillip Parker King.—Between Flinders and King there was no serious attempt to explore the coast; occasionally merchant vessels reported patches of reef, and some surveying was done by Lieutenant Charles Jeffreys in H.M. brig *Kangaroo* near Newcastle and in Tasmania. Flinders had left practically untouched the coast-line west-about from Arnhem Land to the Leeuwin, but a good deal was known as far north as Shark Bay; in 1817, therefore, Lieutenant Phillip P. King (q.v.) was instructed by the admiralty to proceed to Sydney and complete the survey, Macquarie being asked to supply him with a small vessel suitable for the service. The *Mermaid* (a cutter of 84 tons burthen) arrived from India just after King landed, and was purchased for £2000. Her complement of 19 included Allan Cunningham the botanist and Bongarie, the aboriginal who had been with Flinders. She left Sydney on 22 December 1817. It was decided to begin the survey at North-west Cape, and to proceed there via King George's Sound, which was reached on 20 January 1818. In spite of several accidents during the first month of his surveying, King managed to accomplish a good deal of useful work: he examined 'the great bay of Van Dieman,' corrected the observations of Dampier and Baudin, fixed the position of the Imperieuse and other shoals, added many new discoveries, some of major importance, to the chart, and returned to Sydney to refresh on 29 July 1818. The construction of the charts of this voyage (which represented 500 miles of coast surveyed) occupied him in Sydney until December 1818, after which he decided to make a survey of Macquarie Harbour, then lately discovered. The *Mermaid* sailed on 24 December, and on the way King noted that Cook's 'Red Point' really consisted of five islands and that the natives called the district Illawarra. On 10 January 1819 the *Mermaid* left Hobart, passed through D'Entrecasteaux Channel (then 'improperly called by the colonists Storm Bay Passage'), was in Outer Bay on the 17th, buoyed Kelly's Channel, chartered Macquarie Harbour, and on 29 January was back in Hobart. On 8 May she sailed from Sydney for Torres Straits via Port Macquarie, accompanied by Oxley in the *Lady Nelson* bound to examine Port Macquarie. King was at Port Macquarie on 10 May and with Oxley examined Camden Haven and the Hastings, noting the abundance of 'what the colonists call the Swamp Oak;' on 21 May the *Lady Nelson* returned to Sydney. The *Mermaid* was off Mount Warning on 23 May, and King felt sure from what he saw that there must be a big river-mouth in the neighbourhood; Oxley in 1823 discovered the river, and named it the Tweed. On his way up the coast and through Torres Straits King made numerous additions to the discoveries of Cook, Flinders, and the Dutch and French explorers. At the Endeavour River he found the local native tribes unfriendly—an experience which Cook had had, and which King was to repeat in an aggravated form two years later. Near the western head of Bathurst Bay he found the deserted wreck of the *Frederick*, which had sailed from Sydney early in 1818—one of the long list of shipwrecks that was to mark this dangerous passage for years to come. Passing Torres Straits and crossing the Gulf, he resumed his survey of the north coast at the Wessel Islands, discovered the Liverpool River, crossed Van Diemen's Gulf, and passed the entrance to Port Darwin without thinking it worth investigation, but made a thorough examination of Cambridge Gulf. By the middle of October, when he was in Admiralty Gulf, he felt the necessity for refreshing his crew, made for Savu in the Malays, and anchored there on the 24th; the next day he sailed for Koepang, and reached Sydney west-about on 12 December, having surveyed 540 miles of coast. On 13 July 1820 he sailed again, and on 14 August found a board on Booby Island narrating the safe passage so far of the *Sea-Flower*—a vessel that left Sydney on 21 May, took the outer passage, and entered Torres Straits past Murray Island after a 21 days' passage; this showed that merchant ships were already beginning to take the outer route with confidence. On 6 September at Montague Sound the survey was commenced again, but on the 20th the cutter began to leak badly. They managed to reach Brunswick Bay; there, as they had already lost two anchors, the weather was bad, and the crew began to grow sickly, it was decided to return to Sydney for a thorough overhaul and the *Mermaid* reached port on 6 December 1820.

The *Mermaid* was now surveyed, and condemned for this particular service, but was subsequently repaired and served in New South Wales waters for years. A teak-built brig of 170 tons was purchased and renamed the *Bathurst;* the total complement was increased to 33, and they were now able to carry a long-boat—a resource they had not possessed in the *Mermaid.* The *Bathurst* sailed on 26 May 1821. In Bathurst Bay they had disquieting encounters with the natives, and on Clack Island, not far away, Cunningham discovered a remarkable aboriginal picture-gallery. The survey began again at Brunswick Bay; Hanover Bay and King Sound were thoroughly examined, and the coast-line charted with great exactness to a little west of Roebuck Bay. Thence King made for the Mauritius, refitted, made back to King George's Sound, recommenced his survey at Rottnest Island near Fremantle, and thence worked northwards round North-west Cape to King Sound. On 20 February 1822, finding himself short of provisions, with only one anchor left, and threatened with a spell of

stormy weather, King decided to end his work and make back to Port Jackson. On 15 April he was in Bass Strait; on the 25th he reached Sydney, to find that he was to take the *Bathurst* to England 'when the survey should be completed.' As nothing more could be done on the north-west coast until the following year, he decided to go to England at once. On 25 September he sailed: on 6 October he was south of Tasmania, correcting Flinders's charts (which here were unusually inaccurate); thence he made his way via King George's Sound, Simon's Bay and St. Helena to Plymouth, which he reached on 23 April 1823.

The 'Beagle'.—The next serious attempt to survey the coast of Australia was begun in 1837. From 1826 to 1836 P. P. King was employed by the admiralty on a survey of the coast of South America with the *Adventure* and *Beagle*, and during his term had under him in the *Beagle* Captain Fitzroy (afterwards governor of New Zealand) as commander (1828-36), Owen Stanley as a midshipman (1831-6), Conrad Martens as artist (1832-4), and Charles Darwin as naturalist (1831-6). Australia was visited, and Darwin recorded the visit in his *Voyage of the 'Beagle,'* but no explorations were made here. In 1837, however, the *Beagle* was recommissioned under Captain J. C. Wickham for the survey of Bass and Torres Straits and of that part of the north-western coast which Flinders and King had either neglected or treated sketchily. George Grey and Franklin Lushington embarked with Wickham, but left the ship at Cape Town to hire a schooner and make for Hanover Bay, where they began the journey described under EXPLORATION BY LAND. The *Beagle* reached the Swan River on 1 November 1837, and Wickham, after resurveying Roebuck Bay (Jan. 16-22) and the outer part of King Sound (Jan. 27 to Feb. 23), took up King's interrupted work at Disaster Bay and on the 26th discovered and named the Fitzroy River. Working northwards along the coast, on 15 April he met Grey's party near Hanover Bay, and then made his way back to Swan River and so to Hobart and Sydney (24 July), whence on 11 November the *Beagle* sailed to survey Bass Strait.

On 22 May 1839 Wickham sailed again for the north-west, running up the coast of New South Wales and commencing his discoveries with an island off Cape Capricorn. Having in 1838 fraternized in Port Jackson with the expedition under Bremer and Owen Stanley that was to make a settlement at Port Essington, he made straight for that port and, during investigations in neighbouring waters, discovered on 27 July the Adelaide River; but the real work of this cruise was done after leaving Port Essington on 4 September, and included the discovery and charting of Port Darwin and Bynoe harbour (9 to 26 September) and of the Victoria River (17 October to 12 December). The year 1840 was occupied with resurveys of areas on the west coast, at King George's Sound, and in Bass Strait, and it was not till the end of May 1841 that the *Beagle* (now under Captain Lort Stokes, Wickham having been invalided to England) left Port Jackson for another cruise of exploration. This time she doubled into the Gulf of Carpentaria, surveyed its southern end, and discovered the Flinders (28 July) and Albert (1 August) rivers, and on the latter an area of rich land which Stokes called the 'Plains of Promise.' The rest of her term in Australian waters (which lasted until 6 May 1843) was devoted to surveys of areas that were already roughly known; these, like the subsequent work of the *Fly* (1842-5), the *Rattlesnake* (1847-50), and the *Basilisk* (1871-4) hardly come under the heading of exploration.

W. J.

Eyre, EDWARD JOHN (1815-1901), born at Hornsea in Yorkshire on 5 August 1815 and educated at Louth and Sedbergh, was intended for the army, but at the age of 17 found that he must wait yet longer for a commission and impatiently took the purchase-money, migrated to Sydney, and busied himself in droving cattle and sheep to the new settlements on and beyond the Murray. In 1837 he conceived the idea of taking stock across country to the just-founded settlement at Adelaide, which was then reached only by sea; and, organizing his party on the upper Murray and obtaining supplies from Port Phillip, he on 9 February 1838 started west past Castlemaine and across the Loddon to the Wimmera, which he followed to Lake Hindmarsh. Here he found himself in thick waterless scrub, and was forced to return to the Loddon, follow it to the Murray, and make for Adelaide by a track along that river already pioneered by Joseph Hawdon. In 1839 he made two expeditions, one from Adelaide to Mount Arden north of Spencer Gulf (during which he sighted Lake Torrens), the other from Port Lincoln to and beyond Streaky Bay and back to Mount Arden. Having found himself almost continuously in barren and waterless country, he came to the conclusion that it was useless to attempt the discovery of a stock route westwards, and that the only field for explorers lay to the north. Accordingly—after a short visit to Western Australia early in 1840, during which he drove stock from Albany to Perth—he on 18 June 1840 left Adelaide with an expedition intended to penetrate the unknown region east of Lake Torrens. After two attempts—in one of which he reached Mount Deception, in the other Mount Hopeless—he abandoned the northern route, sent his party across to Streaky Bay, obtained fresh stores from Adelaide via Port Lincoln, moved the expedition as far as Fowler's Bay, and made several attempts to take it farther westwards. In January 1841 he determined to send the expedition back to Adelaide and try to force a way through to King George's Sound with packhorses only. Starting on 25 February, accompanied only by one white man (Baxter) and three blackfellows, he spent two months in skirting the Bight, here bordered by a plateau entirely destitute of water; on the evening of 29 April two of the natives murdered Baxter and stole most of the stores; and for another month Eyre and one blackfellow (a native of King George's Sound) continued their desperate journey until on 2 June they found a French whaler lying in Thistle Cove, a little E. of Esperance. Replenishing their stores from this friendly vessel, the travellers reached Albany on 7 July, and by the 26th Eyre was back in Adelaide.

From October 1841 to November 1844 Eyre was resident magistrate and protector of aborigines in the Murray district of South Australia, and proved himself one of the kindliest and most judicious officers ever placed in contact with the wild native tribes. In 1844 he twice offered to lead an expedition from Moreton Bay to Port Essington; but Gipps considered that Sir T. Mitchell had the prior right to this exploration, and Eyre in 1845 went back to England for his health's sake. There he

published his *Journals of Expeditions of Discovery*, in which he included a long and valuable study of aboriginal habits that has not yet lost its value. His subsequent career had no connection with Australia. From 1846 to 1853 he was lieutenant-governor of New Zealand under his friend Sir George Grey, in 1854-60 governor of St. Vincent in the West Indies, in 1860-1 acting governor of the Leeward Islands; in 1861 he became acting governor of Jamaica, and in 1864 received the permanent appointment. There in the following year he was confronted with a serious negro mutiny, promptly suppressed it, and in so doing irregularly hanged a negro member of the local legislature who was undoubtedly an agitator among the mutineers. The ensuing scandal caused his reprimand and recall; but in England an outcry against him led by John Stuart Mill, T. H. Huxley, and Herbert Spencer was counter-balanced by a body of supporters among whom Carlyle, Tennyson, and Ruskin were prominent, and the final result of much agitation and two legal trials was that in July 1872 the Gladstone ministry, with the approval of parliament, paid his legal expenses from public funds. In 1874 Disraeli allotted him the pension due to a retired colonial governor, and he lived in seclusion from that time until his death on 30 November 1901.

agus. See NOTHOFAGUS.

Fairfax, JOHN (1804-1877), born at Warwick in England in 1804, was at the age of 12 apprenticed to a local printer and afterwards worked on the *Morning Chronicle*. In 1825 he settled at Leamington as a printer, and published a small newspaper, the *Leamington Spa Chronicle;* but an action for libel brought against him by a town official, although he won it, ruined him commercially, and he migrated to Australia in 1838, reaching Port Jackson in the *Palmyra* on 26 September. On 1 April 1839 he obtained an appointment as librarian to the Sydney subscription library (which afterwards became the public library of New South Wales). Shortly after this he was engaged by F. M. Stokes of the *Sydney Herald* to set up type and do other work after office hours, and proved so valuable an assistant that the management of the paper was gradually transferred to his hands. On 2 September 1840 the *Herald* began its daily issue; on 8 February 1841 it passed into the possession of John Fairfax and Charles Kemp (a reporter on the staff), and on 1 August 1842 appeared for the first time as the *Sydney Morning Herald*. Fairfax had in February 1841 resigned his position at the library, and thenceforth devoted himself to the management of the paper, of which in 1853 he became sole proprietor. In 1857 he took in his sons as partners. Outside his office he was a prominent and useful citizen, and took a large part in establishing the Australian Mutual Provident Society on a firm basis. In 1871 he was appointed to the council of education, and in 1874 was nominated to the legislative council. He died at Sydney on 16 June 1877.—His second son, SIR JAMES READING FAIRFAX (1834-1919), born at Leamington on 17 October 1834 and educated at Parramatta and Sydney under Dr. Woolls and Henry Cary, was at the age of 17 given employment in his father's office, taken into partnership in 1857, and in 1888 took over the active management of the paper. Like his father, he devoted his life to the *Herald*; but he was also a founder and high official of the national art gallery, the Prince Alfred hospital, the royal naval house, the national rifle association, the boys' brigade, and the Y.M.C.A., a director of two banks and several business firms, vice-president of several musical societies, and commodore of the royal yacht squadron. He died at Sydney on 28 March 1919.

Farming. See AGRICULTURE.

Farrell, JOHN (1851-1904), was born on 18 January 1851 at Buenos Aires in South America, brought by his parents to Victoria at the end of 1852, reared on his father's farm near Maldon on the Victorian Loddon, and privately educated. In 1870 he began work at a brewery in Bendigo, and for the next 17 years was mainly employed in that trade, with short intervals during which he tried gold-mining in northern Queensland (1873-4) and farming at Benalla (1876-7). In 1887, when he was part-owner of a brewery at Queanbeyan, he determined to abandon the trade altogether and take to journalism.

From 1876 onwards he had been writing occasional verse and prose for local newspapers, and in 1882 became a contributor to the *Bulletin*. His best-known poem, 'How He Died'—which was read and approved by Tennyson—appeared in that journal on 21 July 1883, and his first book of verse (named after the poem) in January 1887. Between those dates—at some time in 1884—he had read and delighted in Henry George's *Progress and Poverty*; and the double thread of authorship and political enthusiasm drew him from trade to letters. He bought a newspaper circulating in the Lithgow district, made it a literary success but a financial failure, obtained the editorship of a 'single tax' journal that was published first at Lithgow and then in Sydney, and finally settled down as leader-writer to the Sydney *Daily Telegraph*. This post he occupied from February 1890 to June 1903, with an interval (June-September 1890) during which he was editor of the paper. Journalism, however, was almost fatal to verse; after 1887 he wrote very little, though his two best poems belong to the later period—'Australia,' a fine piece of eloquence written for the *Picturesque Atlas of Australasia* in 1888, and 'Ave Imperatrix' (afterwards published as *Australia to England*), written for the diamond jubilee of Queen Victoria, which was not only Farrell's but the Empire's high-water mark in patriotic verse. His health had for many years been bad—not because of his trade, for it is hard to believe that any other brewer ever made so little use of his own goods; and at the end of 1903, possibly because the strain of incessant active work had been removed, he broke down altogether. He died in hospital of heart failure on 8 January 1904. See LITERATURE.

Farrer, WILLIAM JAMES (1845-1906), son of a Westmoreland landowner, was born on 3 April 1845, educated at Christ's Hospital and Pembroke College, Cambridge (B.A., 1868; wrangler), and studied for the medical profession, but abandoned this intention on account of ill-health and migrated to Australia in 1870. Here he worked at first as tutor in the family of the Campbells of Duntroon, then (losses in mining speculations having swallowed up the capital with which he had hoped to purchase a sheep-station) as a surveyor; in 1875 he entered the New South Wales department of lands as a contract surveyor, and worked in the Dubbo, Cobar, and Cooma districts until 1886. In that

year he resigned, and settled at Lambrigg near Queanbeyan, where he commenced to experiment in hybridizing wheats with the object of finding rust-resisting or rust-proof varieties. The annual loss from rust in Australian wheat was at that time estimated at £2,500,000. For the next 11 years Farrer pursued his experiments steadily at his own farm, developing his researches so as to include the improvement of the milling value of wheats; for this purpose he invited and received the ungrudging help of F. B. Guthrie, chemist to the department of agriculture, who had specialized in this subject. In 1898 Farrer was made wheat experimentalist to the department of agriculture; this enabled him to command more help and a greater variety of soils and climates for testing purposes, and gave him, for growing his seed-wheat, areas sufficiently large to let him distribute it to farmers for general cultivation. Eight years, however, of hard and constant work wore him down; early in 1906 he began to acknowledge overstrain, and on 16 April in that year he died.

In the pursuance of his objective—the improvement of wheat so as to get the best results under Australian conditions—Farrer was driven to produce a large number of varieties, each with characteristics suitable to encounter some or all of the exceedingly diversified conditions imposed by the very various Australian soils and climates. He had not only to press upon his creations powers of resistance to rust, or of resistance to or immunity from smut and bunt, but to provide wheats suitable to the coastal districts and tablelands as well as to the semi-arid western areas; wheats specially adapted for hay as well as 'dual-purpose' wheats (which enable the farmer either to allow his grain to ripen, or in the case of adverse seasons to save it by cutting it for green feed or hay); wheats with short stiff straw, enabling the crop to resist wind-storms; wheats which mature early or late or in mid-season; wheats which hold their grain well and thus escape the serious loss by shelling that was common with many of the older varieties; wheats of high gluten content, and consequently of great nutritive value; above all, wheats of high milling excellence and greater commercial value than were the varieties previously in cultivation in Australia. He never allowed a variety to be distributed unless he was sure that it could produce a flour of high quality.

Of the actual value of his work to Australia it is difficult to speak highly enough. Few men have so persistently fought their way through against such discouragements and embarrassments as fell to his share; fewer still have won so lasting a triumph, have so fully achieved their desires, and given their country so great and permanent a gift. The work he undertook was colossal; for the making of any given strain scores of crosses had to be prepared (he actually made from 200 to 400 annually), the grain from each plant had to be sown separately, and the result of a whole year's toil might be only a few grains from one ear. His best-known creation—'Federation' wheat—transformed growing conditions in New South Wales, Victoria, and South Australia, and his 'Florence' is doing the same for Queensland; with them he made it possible to extend the area under cultivation into districts previously considered quite unsuitable for wheat. The increase in the average acre-yield of grain due to the general use of these wheats has been estimated at about two bushels; as the average acre-yield in New South Wales is about 12 bushels, this represents an increase of over 16 per cent on the total harvest. Moreover, the increase in the value of Australian wheat in the world's markets due to Farrer's work has been estimated at 2s. a quarter at least.

And the lesson has been learnt. Of the many strains generally cultivated prior to 1900 not more than two or three are now grown to any extent; the rest have been replaced either by Farrer wheats or by strains bred from them. And, if his products are nowadays not so outstanding as in 1906, but have their place among other greatly improved varieties, it is largely because his efforts and success encouraged other experimenters. In 1904 British experts were still asserting that 30 years of cross-breeding had failed to produce a single marketable variety, and were warning agriculturists against expecting practical results from 'these abstruse experiments in cross-fertilization.' Even then Farrer had disproved their words; since then his reputation has become world-wide, and his example has filled the laboratories of Britain and the United States with emulative followers.

Soon after his death it was decided to commemorate his work by raising a fund out of which the expense of further researches should be met. Although the response was disappointing—even discreditable—enough was obtained after some years to institute a Farrer research scholarship; in 1920-22 the first scholar studied in Britain and America, and in 1923-4 the second investigated the root development of wheat and similar subjects at Sydney and at the Wagga experimental farm.

Faucett, PETER (1821-1894), born in Dublin and educated at Trinity College (B.A., 1842), was called to the Irish bar in 1845, migrated to New South Wales in 1852, was admitted to the local bar, and in 1856 entered politics as member of the legislative assembly for King and Georgiana. This seat he held till 1859; in 1860 he was member for East Sydney; and from 1861 to 1865 he represented Yass Plains, being solicitor-general in the first Martin ministry from October 1863 to February 1865. In October of the latter year he left politics to become a judge of the supreme court, in which capacity he acquired a reputation for painstaking accuracy. In February 1888 he retired from the bench, and in April was nominated to the legislative council. From 1859 until his death he was a fellow of the senate of the university of Sydney. He died on 22 May 1894.

Favenc, ERNEST (1845-1908), born in London on 21 October 1845 and educated at Berlin and Crowley, migrated to Sydney in 1863 and, after a short experience of commercial life, spent many years in opening up new pastoral country and droving cattle in northern Queensland. In 1878 he was chosen leader of an expedition sent out by the *Queenslander* newspaper to explore unknown districts lying between the Barcoo River and the overland telegraph line through central Australia, as there was talk of constructing a railway line in that direction; an account of this journey will be found under EXPLORATION BY LAND. In subsequent journeys he (*a*) in 1882-3 mapped the upper courses of the Gulf rivers of western Queensland, and traversed the region between the Macarthur River and Daly Waters on the telegraph line, and (*b*) in 1889 investigated the upper Gascoyne and Ashburton. Favenc, who

did a good deal of journalistic work, published a small volume of verse and several collections of tales; but his chief book is *The History of Australian Exploration, 1788-1888*, published in 1888 at the expense of the New South Wales government, and still a standard work on the subject. He also published in 1908 a shorter account of *Explorers of Australia*. He died on 14 December 1908.

Fawkner, John Pascoe (1792-1869), born in London on 20 October 1792, was ten years old when his father was convicted of receiving stolen goods and sentenced to transportation. The family was allowed to accompany the father in the *Calcutta* (one of the vessels sent with David Collins, q.v., in 1803 to establish a settlement on Port Phillip), and went on with him in the *Ocean* to Hobart. Here the elder Fawkner was emancipated and allowed to settle on a 50-acre block in the Glenorchy district, where he throve moderately. His wife went back to England in 1806 as lady's maid to an officer's wife—a fact which may account for the vagrant life into which young John Fawkner thenceforward fell—but in later years returned to Tasmania and died there in 1825. The lad worked in the bush as a sawyer; in 1814 he aided the escape of some Portuguese convicts, was caught, and was deported to New South Wales 'to break the chain of a very dangerous connection which he has formed in the settlement:' returning to Hobart in 1817, he farmed land near his father, made a failure of it, tried baking and timber-selling, shifted to Launceston in 1819, there tried baking and timber-selling again, and gradually added to these activities those of butchering, bookselling (with a circulating library attached), nursery-gardening, coach-owning, and giving lessons in French. In 1824 he built and began management of the Cornwall Hotel, and in 1829 founded and edited the *Launceston Advertiser*. This, the first newspaper published in Launceston, reflected its owner's bitterness against nearly all authority, and he soon lost his hotel licence for libelling the local magistrates and was compelled to part with the newspaper. By making a public apology he was reinstated in the hotel, and for the next few years practised as an advocate in the lower courts of justice. By 1835 he had established a reputation as a fearless and vindictive fighter, and was one of Launceston's most influential citizens.

According to his own story he made plans early in 1835 to establish a small settlement on Western Port, and chartered in Sydney a vessel of 55 tons, the *Enterprise*, to take his assistants across the strait. While he was impatiently awaiting the vessel's arrival in the Tamar, John Batman (q.v.) on 11 June appeared in Launceston with the story of his great purchase of good grazing country on Port Phillip. Fawkner left in the *Enterprise* on 29 June, but seasickness forced him back to land; his party sailed without him to Western Port, found it unsuitable for settlement, moved into Port Phillip and, skirting the eastern shore of the bay, on 20 August anchored in Hobson's Bay. After a vain exploration of the Saltwater River they worked up the Yarra to the falls that then marked the head of tide-water, and on 31 August began building huts to mark a permanent occupation. On this occupation—at which he was not present, and which, as far as the evidence goes, he had neither intended nor anticipated—Fawkner afterwards based a claim to be considered the founder of the colony of Victoria. Lonsdale, writing as administrator of the settlement in 1837, thought otherwise:—

> The site of the present settlement had been previously chosen by Mr. Batman, but Mr. Fawkner, becoming aware of his plans, hastened to commence operations there and took the other by surprise whilst he was engaged in another part of the Bay.

While, however, Batman's claims to priority in settling Port Phillip definitely (ignoring, that is, the earlier failure of Collins) out-weigh those of Fawkner, it was to Fawkner rather than to Batman that the rise of Melbourne itself was due. Batman's association was one of pastoralists, more concerned with areas fit for sheep-runs than with the commercial activities of a town; and the official division, which in effect allotted to the association lands west of Geelong and to Fawkner's party town-sites on the Yarra, was on the whole a fair and satisfactory division.

Fawkner himself landed on Yarra bank on 10 October and before the end of the year had opened what is described by H. G. Turner as 'a general store and grog-shop.' While during 1836 Batman still took the lead in public affairs, Fawkner was steadily consolidating his position; the grog-shop became a hotel at which a lieutenant-governor's wife could stay; on 1 January 1838 appeared the first issue of the *Melbourne Advertiser*, a manuscript newspaper that ran through nine weekly issues; the tenth was printed, and the paper was immediately suppressed as not complying with the colonial press law. Nothing daunted, Fawkner on 6 February 1839 issued the first number of the *Port Phillip Patriot*, which from 4 July onwards appeared twice a week, and lasted till 1843. On 22 November 1840 he issued for the first time the *Geelong Advertiser*, which still exists. In December 1842 he was elected to the first town council, but behaved so vehemently there that he was ejected in 1843. As he grew older, however, his violence moderated, and he was recognized as an eccentric but effective leader in the community. In 1851 he was appointed to the goldfield discovery committee and elected a member of the first legislative council; in 1854 he even took the constitutional side in the disputes after the Eureka riots; in 1856 he was elected to the new legislative council, and held his seat till a short time before his death, which occurred on 4 September 1869. During these later years, though a bitter opponent (as always) of the squatting interests, he was otherwise a conservative, deprecating the introduction of the ballot and the reduction of the property qualification for council members and electors.

Federal Capital, The. See Canberra.

Federation. The early history of Australia is a record of separation. The first colony, New South Wales, when founded in 1788 comprised the whole continent east of the 135th meridian, together with Tasmania and (later) New Zealand. The developments of the first 71 years included the gradual lopping off of pieces of this territory, and the recognition of them as separate colonies, until only the portion now known as New South Wales remained. But almost as soon as the separating process commenced it was found wise to modify it by various attempts at re-linking the separated parts. In 1842 the legislative council of New South Wales passed an act to admit free of duty manufactured articles or produce from

Tasmania and New Zealand; the act, however, was disallowed by Lord Stanley, then colonial secretary, on the ground that 'a policy of discrimination would involve the commercial treaties and the foreign relations of Great Britain, and could not be satisfactorily dealt with except by the home government.' The fiscal policies of the colonies, differing as they did, soon created friction, and led Sir Charles Fitzroy on 29 September 1846 to write as follows to the colonial office:

> It appears to me that, considering its distance from Home, and the time that must elapse before the decision of Her Majesty's Government upon measures passed by the Legislatures of these colonies can be obtained, it would be very advantageous to their interests if some superior functionary were to be appointed, to whom all measures adopted by the local Legislatures, affecting the general interests of the mother country, the Australian colonies, or their intercolonial trade, should be submitted by the officers administering the several Governments, before their own assent is given to them.

This is the first recorded proposal for a central authority to deal with matters of common concern. On 31 July 1847 Earl Grey, then colonial secretary, outlined the first project for a national assembly. After enumerating the reasons for the creation of some central legislative assembly, he added:—

> Some method will also be devised for enabling the various legislatures of the several Australian colonies to co-operate with each other in the enactment of such laws as may be necessary for regulating the interests common to those possessions collectively. Such, for example, are the imposition of duties of import and export, the conveyance of letters, and the formation of roads, railways, or other internal communications traversing any two or more of such colonies—The subject of your own despatch of the 29th Sept., 1846, viz., the imposition of discriminating duties in any Australian colony, on goods, the growth, produce or manufacture of any other Australian colony, will also be adverted to, and provided for, in that part of the contemplated Act of Parliament which will relate to the creation of a central legislative authority for the whole of the Australian colonies.

In New South Wales the proposal was not received with any enthusiasm; it was mildly approved as unobjectionable, and possibly even useful, but of little immediate importance. The report of a committee of the privy council appointed in 1849 'to enquire into the constitutional changes which it might be advisable to make in the Government of the Australian colonies' carried the proposals a step further; the committee was of opinion that a uniform tariff should be established, with intercolonial freetrade, and proposed that

> One of the Governors of the Australian colonies should always hold from Your Majesty a commission constituting him the Governor-General of Australia. We think that he should be authorized to convene a body to be called the General Assembly of Australia, at any time and at any place within Your Majesty's Australian dominions which he might see fit to appoint for the purpose. But we are of opinion that the first convocation of that body should be postponed until the Governor-General should have received from two or more of the Australian legislatures addresses requesting him to exercise that power.
>
> We commend that the General Assembly should consist of the Governor-General, and of a single House, to be called the House of Delegates. The House of Delegates should be composed of not less than 20 nor more than 30 members. They should be elected by the legislatures of the different Australian colonies.

The bill which was introduced in 1849 for the separation of Victoria also provided for the creation of a general assembly on the lines of the report, and in a schedule set forth a uniform tariff; but these provisions were ultimately abandoned as premature, and the act for the separation of Victoria contained no reference to a federal authority. Earl Grey, however, did not wholly abandon the federal idea, and in 1851 sent out to the governor of New South Wales, besides four commissions appointing him governor of New South Wales, Tasmania, South Australia, and Victoria, a fifth appointing him 'Governor General of all Her Majesty's Australian possessions, including the colony of Western Australia.' Fitzroy was instructed not to interfere in internal administration, but to foster 'the completion of measures calculated to promote the common welfare' and the lieutenant-governors of Tasmania, Victoria, and South Australia were instructed to communicate with him on all measures affecting intercolonial interests. Only once did the governor-general actually concern himself with intercolonial interests. In 1855 Sir W. Denison (then governor of New South Wales) endeavoured to secure harmony between the tariffs of New South Wales and Victoria; but shortly afterwards responsible government was inaugurated in both colonies, and the governor-generalship fell into disuse. Its last shred of utility was, of course, gone when the several governors ceased to exercise control over the administration.

In 1853 a select committee of the legislative council of New South Wales, bringing up a report on a proposed new constitution, expressed the opinion that 'one of the more prominent legislative measures required by this colony, and the colonies of the Australian group generally, is the establishment at once of a General Assembly to make laws in relation to the intercolonial questions which have arisen and may hereafter arise among them.' A similar committee appointed the same year in Victoria also dealt with the question, but its proposals did not include a definite scheme. In the New South Wales proposition a list of subjects upon which the general assembly could legislate was given, but in the Victorian committee's report it was suggested that the body should deal with 'such questions as may be submitted to it by the Act of any Legislature of one of the Australian colonies.'

The constitution acts of 1855 (18 and 19 Vic. cc. 54-5) omitted any provision for a general assembly, and Lord John Russell, then colonial secretary, in a despatch stated that the matter had been considered and the government had concluded that the time was not opportune. In 1854 the project was kept alive by a series of letters in the *Sydney Morning Herald*, written by John West under the nom-de-plume of 'John Adams,' and in 1856 Edward Deas Thomson mentioned in the council the probability of some federal arrangement; but the next important stage was 'Wentworth's Memorial.' W. C. Wentworth, who had gone on a visit to England in 1854, in 1857 submitted to the colonial office a memorial and the draft of a short enabling bill, which had been adopted at a meeting of the General Association for the Australian Colonies, held in London on 31 March. The memorial referred to the necessity of a federal authority, and recommended the Imperial government to give, by means of a permissive act, 'to the legislatures of any two or more colonies a per-

missive power to form a federation themselves.' Complete equality of representation, as between all the Australian colonies, should be insisted upon without reference to the relative populations, and the federal assembly might in the first instance be 'perambulatory.' The bill empowered any two or more colonial legislatures to form a convention 'for the purpose of creating a Federal Assembly,' but laid down only a few rules as to its constitution. At the colonial office the scheme did not meet with a favourable reception; its acceptability in Australia was doubted, but copies of the correspondence were sent to the several governors.

In January 1857 Charles Gavan Duffy obtained the appointment of a select committee of the Victorian assembly 'to enquire into and report upon the necessity of a federal union of the Australian colonies for legislative purposes and the best means of accomplishing such a union if necessary.' The committee was unanimous as to the ultimate necessity of a federal union, and thought it was too soon to invite a mutual understanding on the subject; it recommended a conference (three delegates from each legislature) 'to frame a plan of federation to be afterwards submitted for approval, either to the Legislature or directly to the people, or both, and to receive final legislative sanction.' The recommendations were adopted by both Victorian houses, and forwarded to the other colonies. In New South Wales in August of the same year (1857) Deas Thomson obtained a select committee of the legislative council on the same subject. This committee endorsed the Victorian proposition, and put forward the outlines of a scheme. Had it been well backed up, union might have been achieved. Unfortunately, however, other influences were at work. During the deliberations of the committee, the Parker ministry (of which Deas Thomson was a member) had been replaced by a Cowper ministry with James Martin, its attorney-general, as its dominating personality. Neither Cowper nor Martin cared anything for federal union, and colonial politicians in general were engrossed in such questions as the franchise, the reform of the upper house, and the land question. Moreover, the rivalry between New South Wales and Victoria was already leading to jealousy and bad feeling, since the stream of immigration to the goldfields had suddenly given Victoria the lead in population; and Duffy's overtures were received with suspicion as part of a scheme of Victorian aggrandizement. Deas Thomson succeeded in securing the adoption of his report by the council; the assembly was asked to concur, and joint resolutions, based on the Victorian recommendations, were agreed to in conference; their consideration by the assembly was fixed for 18 December, and on the 17th the Cowper ministry was defeated on a crown lands bill, and a dissolution followed. On the reassembling of parliament in March 1858 the federal question was shelved; the assembly resolved that the discussion 'may, under existing circumstances, be deferred,' whilst the council resolved more emphatically that it 'must, under existing circumstances, be deferred.' Deas Thomson seems to have then resigned himself to the inevitable.

In South Australia a select committee in 1857 was of opinion that the promotion of a federal legislature would be premature; it adopted the Victorian proposal for a conference, but delegates were only to 'discuss and report.'

From 1857 to 1860 the history of the movement is a record of select committees and resolutions only. Duffy obtained committees of the Victorian assembly in December 1857 and January 1860; Tasmania resolved to appoint delegates to any conference; but the stumbling block was New South Wales. William Forster, who became premier in 1859, was no more enthusiastic than his predecessors. Even if New South Wales had fallen into line and a conference been held, it is doubtful if any practical result would have followed. To quote Quick and Garran:—'In no colony was there any general enthusiasm, or even interest, in the subject; though in all there were a few far-sighted statesmen who recognized the essential unity of Australia. Even in Victoria, whose statesmen showed the most eagerness for union, there was nothing approaching a real federal movement. Local politics, and the development of local institutions, engrossed the attention of the people; and probably no colony would have been prepared to accept the compromises and the partial sacrifices of local independence which a federal union would have involved. The best justification of the inaction of the Imperial Government is the want of interest shown by the colonies themselves.'

From 1863 to 1880 questions requiring concerted action were dealt with by intercolonial conferences. At one held at Melbourne in March 1867, Henry Parkes made a memorable speech:—'I think the time has arrived when these colonies should be united by some federal bond of connection . . . . there are questions projecting themselves upon our attention, which cannot be satisfactorily dealt with by any one of the individual Governments. I regard this occasion, therefore, with great interest, because I believe it will inevitably lead to a more permanent federal understanding.' In 1870 Duffy in Victoria made another effort to advance federation by securing the appointment of a royal commission to consider the subject; but, beyond a preliminary report nothing was done. At an intercolonial conference which met at Melbourne in November and December 1880 to discuss the subject of a uniform tariff, resolutions passed at the instance of Henry Parkes affirmed the desirability of creating a federal council, and New South Wales was requested to prepare the necessary bill. A bill was accordingly submitted to the conference at a later meeting in January 1881; the accompanying memorandum stated that in respect to the federal council bill now submitted, the following positions are assumed as hardly open to debate:—(1) that the time is not come for the construction of a federal constitution, with an Australian federal parliament; (2) that the time is come when a number of matters of much concern to all the colonies might be dealt with more effectually by some federal authority than by the colonies separately; (3) that an organization which would lead men to think in the direction of federation and accustom the public mind to federal ideas, would be the best preparation for the foundation of federal government. In a division on the acceptance of the bill New South Wales, South Australia, and Tasmania voted for the bill, and Victoria, Queensland, and New Zealand against, the Western Australian delegates abstaining from voting. The proposal was therefore abandoned.

The Federal Council.—Up to this point every effort to effect a federation of any kind had

been abortive. But in June 1883 the junction of the railway system of New South Wales with that of Victoria was effected, and during the accompanying festivities reference was made to federation. James Service, the Victorian premier, said 'We want federation, and we want it now,' but other speakers were not so enthusiastic. The most powerful incentive to federation, however, came from outside. In 1883 rumours were in the air that Germany had designs on New Guinea, and that France was coveting the New Hebrides and intended to transport to New Caledonia a number of recidivistes or habitual criminals. The executive council of Queensland on 17 July resolved that the imperial parliament should be invited to move in the direction of federal union. Service took more practical action by inviting an intercolonial conference, which met in Sydney on 28 November, seven colonies and Fiji being represented. Service was for federation 'pure and simple,' but the other delegates were not prepared to follow him. On the motion of Samuel Griffith, premier of Queensland, it was decided that a federal Australasian council should be created, and a bill (drafted by Griffith) was adopted by the convention. Each self-governing colony was to have two representatives on the council—crown colonies were to have one. The council was to be a legislature merely, with no executive powers and no control over revenue or expenditure. Even its legislative powers were very scanty, the matters over which it was given independent legislative authority being only seven. Foremost of these were 'the relations of Australasia with the islands of the Pacific' and 'prevention of the influx of criminals'—the two burning questions which had led up to the convention. The others related to fisheries in Australasian waters outside territorial limits, the service of civil process beyond the limits of a colony, the enforcement of judgments and of criminal process beyond the limits of a colony, the extradition of offenders, and the custody of offenders on government ships beyond territorial limits. Those were the only matters on which the council could legislate on its own motion. There was a second list of matters which the legislatures of two or more colonies might refer to the council, and on which the council might then legislate, but only so as to affect the referring or adopting colonies. This list comprised defence, quarantine, patents and copyright, bills of exchange and promissory notes, weights and measures, recognition of marriage and divorce, naturalization, status of corporations, and 'any other matter of general Australasian interest with respect to which the legislatures of the several colonies can legislate within their own limits, and as to which it is deemed desirable that there should be a law of general application.' All laws of the council were to be presented, for the royal assent, to the governor of the colony in which the council was sitting.

In July and August 1884 addresses praying for the enactment of the bill were passed by the legislatures of Victoria, Tasmania, Queensland, Western Australia, and Fiji, but New South Wales and New Zealand stood aloof. In New South Wales resolutions approving of the bill were brought before both houses of parliament; in the council the resolutions were carried by 13 to 9, in the assembly they were defeated by one vote. John Robertson and others frankly opposed union on the ground of mistrust of the other colonies; but the most general objection was that the scheme was premature, ill-conceived and ineffective. Henry Parkes referred to the proposed council as a 'rickety body,' and contended that it would impede the way for a sure and solid federation. The British government, acting on the addresses presented to it, decided to proceed with the matter, and passed 'The Federal Council of Australasia Act 1885' which became law on 14 August of that year. The act differed in some respects from the bill adopted by the convention. In the first place, a provision was inserted giving any colony the power to secede from the council; this was done in the hope that New South Wales might thereby be induced to join, one of the objections of that colony being the irrevocableness of the compact. Next, power was given to the Queen, at the request of the colonies, to increase the number of members of the council; it was hoped that this might lead to the gradual extension and development of federal institutions. Lastly, the council was given power to legislate on any matter which, at the request of the colonial legislatures, the Queen should think fit to refer to it.

Between September and December 1885 adopting acts were passed by Western Australia, Fiji, Queensland, Tasmania, and Victoria, and all these colonies sent representatives to the first meeting of the council, held at Hobart from 25 January to 5 February 1886. The council met again in 1888 and 1889. In December 1888 South Australia agreed to join for two years, but at the end of this period the colony withdrew. From 1891 to 1899 the council met in alternate years, but did little to justify its existence—a fact which its friends ascribed to the aloofness of New South Wales. The council met for the last time in Melbourne in 1899.

The Commonwealth Bill of 1891.—The immediate stimulus that brought about the convention of 1891 arose from the necessity of combined action regarding colonial defence. At the colonial conference of 1887 it was suggested that an imperial officer should be appointed to report on this subject, and in 1889 Major-general Sir J. Bevan Edwards was commissioned to inspect and report. On receipt of the general's report Parkes suggested a consultation of premiers, but Gillies, premier of Victoria, proposed that New South Wales should join the federal council and have the matter discussed by that body. This suggestion did not meet with Parkes's approval; he had come to the conclusion that popular sentiment was now ripe for a definite federal movement, at the head of which he resolved to place himself. At the time he was on a short visit to Brisbane, where he had received encouragement from the leading men of both political parties; and on his return journey he was no sooner within New South Wales territory than he opened out with his famous Tenterfield speech of 24 October 1889. In this he emphasized the necessity of federal defence, for which purpose the federal council would be altogether inadequate, because it had no executive power, and was not directly responsible to anyone; nor would it be enough to ask the imperial parliament to pass an act authorizing the troops of the colonies to unite in one federal army under imperial control. What was wanted was a strong central executive, under the control of the Australian people.

After some hesitation on the part of the

other premiers, Parkes obtained their consent to an 'informal' meeting. Accordingly on 6 February 1890 a conference met at Melbourne. New South Wales sent Henry Parkes (premier) and William McMillan (treasurer); Victoria, Duncan Gillies (premier) and Alfred Deakin (chief secretary); Queensland, Samuel Griffith (leader of the opposition) and John Macrossan (colonial secretary); South Australia, John Cockburn (premier) and Thomas Playford (leader of the opposition); Tasmania, Inglis Clark (attorney-general) and Stafford Bird (treasurer); Western Australia, James Lee Steere (speaker); New Zealand, Captain William Russell Russell (colonial secretary) and John Hall. At the inevitable banquet two famous phrases were born. James Service spoke of the tariff question as 'the lion in the path' which federalists must either slay or be slain by; and Henry Parkes responded that 'the crimson thread of kinship runs through us all.' The convention passed various resolutions, the principal of which pledged the delegates to induce the legislatures of their colonies to appoint delegates to a national Australasian convention. All the colonies agreed, and appointed delegates, but New Zealand's were instructed not to bind the colony in any way. On 2 March 1891 the convention met at Sydney. Sir Henry Parkes, W. McMillan, J. P. Abbott, G. R. Dibbs, W. H. Suttor, Edmund Barton, and Sir Patrick Jennings represented New South Wales. From Victoria came Alfred Deakin, James Munro, W. Collard Smith, Nicholas Fitzgerald, H. J. Wrixson, Duncan Gillies, H. Cuthbert, and William Shiels; from Queensland J. M. Macrossan, John Donaldson, Sir S. W. Griffith, Sir Thomas McIlwraith, Arthur Rutledge, A. J. Thynne, and Thomas Macdonald-Paterson; from South Australia Richard Chaffey Baker, John H. Gordon, Sir John C. Bray, Dr. John A. Cockburn, Sir John W. Downer, Charles C. Kingston, and Thomas Playford; from Tasmania William Moore, Adye Douglas, A. Inglis Clark, W. H. Burgess, Nicholas J. Brown, Bolton S. Bird, and Philip O. Fysh; from Western Australia John Forrest, W. E. Marmion, Sir James G. Lee Steere, John A. Wright, John Winthrop Hackett, Alexander Forrest, and W. T. Loton; from New Zealand Sir George Grey, Captain W. R. Russell, and Sir Harry A. Atkinson. The first act of the convention was to appoint Sir Henry Parkes to the position of president; Sir Samuel Griffith was appointed vice-president. Parkes then submitted a series of resolutions with the object of 'obtaining a preliminary interchange of ideas and laying down a few guiding principles.' They read as follows:—

That in order to establish and secure an enduring foundation for the structure of a federal government, the principles embodied in the resolutions following be agreed to:—

1. That the powers and privileges and territorial rights of the several existing colonies shall remain intact, except in respect to such surrenders as may be agreed upon as necessary and incidental to the power and authority of the National Federal Government.

2. That the trade and intercourse between the federated colonies, whether by means of land carriage or coastal navigation, shall be absolutely free.

3. That the power and authority to impose customs duties shall be exclusively lodged in the Federal Government and Parliament, subject to such disposal of the revenues thence derived as shall be agreed upon.

4. That the military and naval defence of Australia shall be entrusted to federal forces, under one command.

Subject to these and other necessary provisions, this Convention approves of the framing of a federal constitution, which shall establish:—

1. A parliament, to consist of a senate and a house of representatives, the former consisting of an equal number of members from each province, to be elected by a system which shall provide for the retirement of one-third of the members every years, so securing to the body itself a perpetual existence combined with definite responsibility to the electors, the latter to be elected by districts formed on a population basis, and to possess the sole power of originating and amending all bills appropriating revenue or imposing taxation.

2. A judiciary, consisting of a federal supreme court, which shall constitute a high court of appeal for Australia, under the direct authority of the Sovereign, whose decisions, as such, shall be final.

3. An executive, consisting of a governor-general and such persons as may from time to time be appointed as his advisers, such persons sitting in Parliament, and whose term of office shall depend upon their possessing the confidence of the house of representatives, expressed by the support of the majority.

The discussion of these resolutions occupied 11 sitting days. The main debate, extending over two days, was on the power of the senate with regard to money bills—a subject which at one time threatened to wreck the convention. On 18 March three committees were appointed to deal with the constitutional machinery, the financial and fiscal problems, and the judiciary; and in the course of the next 12 days was framed the first draft of a bill to constitute the Commonwealth of Australia. This marks an epoch in the history of the movement. In those few days federation was once for all crystallized into a practical scheme, complete in all its details, though as to many of the details, and even many of the principles, there was still to be keen and protracted dispute.

The deliberations of the committees were private. The last stage in the process of drafting the constitution was completed by a sub-committee consisting of Sir Samuel Griffith, C. C. Kingston, Edmund Barton and Inglis Clark, and on 31 March Sir Samuel Griffith, who had the chief hand in the actual drafting of the bill, brought up a draft bill to constitute the Commonwealth of Australia, to which the reports of the finance and the judiciary committees were appended. This practically completed the convention's work, for, except that the mode of distributing the surplus was readjusted, the bill as it came from the draftsmen was, with a few verbal alterations, adopted in its entirety. A few points of interest claim mention. The word 'Commonwealth' is used for the first time; it was first adopted provisionally for want of a better, but was so apt a description that it came to stay. The fiscal policy and the great inequalities of population were stumbling-blocks; the former was left to the federal parliament to decide, and the latter was minimized by a judicious compromise.

On 9 April the convention dissolved, and it became necessary to submit the bill to the colonial legislatures. In New South Wales there was much delay. When parliament opened in May, Parkes gave notice of resolutions in favour of the bill, but before they could be moved the house was dissolved. In the new parliament, which met in July, a new element—the Labour party, 30 strong in a house of 141—was present. This party supported the government, but was not zealous in the cause of federation, which therefore remained an unconsidered item on the

government's programme until in October Parkes was driven out of office. In Victoria the bill was discussed by both houses and amended in some particulars; there was strong opposition to the admission of New Zealand and ultimately an amendment was carried to exclude it unless it came in as an original State. In South Australia the bill was considered in a leisurely fashion, it being recognized that until New South Wales made a definite decision the movement was lifeless. Ultimately the bill was reported with amendments in December 1892. In Tasmania some effort was made to deal with the question, but on rather different lines. There it was proposed to ask the houses to consider the bill first, and then to remit it to the consideration of a provincial convention elected by the voters of Tasmania. Accordingly in July 1891 a 'Commonwealth of Australia Bill' was introduced by the attorney-general providing for the election of 50 representatives to consider the bill. The draft constitution was also considered by the house in committee. After several adjournments and other delays the business was ultimately shelved, on the ground that Tasmania's part in the matter was to follow, not to lead. Western Australia and New Zealand took little interest in the matter; indeed, in New Zealand an abstract motion by Sir George Grey on the subject of federation, but having no direct reference to the convention bill, was unceremoniously counted out. In Queensland Sir Samuel Griffith announced his readiness, and that of his colony, to follow the lead of New South Wales. All Australia, in fact, was waiting for New South Wales.

When Parkes, the recognized leader of the movement, retired from office in October 1891, the prospects of immediate action in the New South Wales parliament grew faint. George Reid and a large section of freetraders put free-trade before federation; the Labour party put social questions before federation. G. R. Dibbs, the new premier, was no friend of the bill, nor were most of his colleagues; but Barton, who was already recognized as Parkes's federal lieutenant (though in colonial politics they were on opposite sides), accepted the attorney-generalship in the Dibbs ministry on the understanding that he was to have a free hand in dealing with federation, and R. E. O'Connor, also an earnest federalist, took the portfolio of minister of justice.

On 23 November 1892 Barton introduced resolutions approving the main principles of the bill and expressing the opinion that amendments made by the colonial legislatures should be dealt with in a second convention. The same resolutions were moved in the legislative council by R. E. O'Connor on 17 May 1893. Both houses carried the resolutions—and there the matter ended. With the resignation of Barton and O'Connor from the ministry in December (for reasons unconnected with federation) all hope of finalizing federation on the lines of the bill was shattered.

Intervention of the Public.—Up to 1892 the public had not been concerned greatly with the subject of federation, though in Victoria the Australian Natives' Association had done something to stir up popular sentiment. But in March 1893 the annual conference of the association recognized the necessity of kindling popular sentiment, and a deputation from it urged Barton to form a central federation league in Sydney; leagues had already been formed at Corowa and Albury, but the necessity of a central league was apparent. At a public meeting held in the Sydney town hall on 3 July 1893 a central league was created, and at the end of 1893 and beginning of 1894 other leagues were formed in Melbourne, Bendigo, Ballarat, Echuca, and other Victorian towns. In August 1895 a league was formed at Adelaide, in July 1898 at Brisbane, and in July 1899 one at Auckland in New Zealand. On 31 July and 1 August 1893 a conference of leagues was held at Corowa in New South Wales, and was made historically important by a resolution moved by Dr. John Quick—'That, in the opinion of this Conference, the Legislature of each Australasian colony should pass an Act providing for the election of representatives to attend a Statutory Convention or Congress to consider and adopt a Bill to establish a Federal Constitution for Australia, and upon the adoption of such Bill or measure it be submitted by some process of referendum to the verdict of each colony.' This scheme—the essence of which was to substitute a popular for a parliamentary election of delegates to the next convention—was adopted with a slight modification by the central league at Sydney.

Dibbs at Tamworth on 22 May 1894 propounded a scheme of complete unification to take the place of federation, but it was condemned by federalists as impracticable. But George Reid, who succeeded Dibbs as premier on 3 August, immediately placed federation on his programme. At a conference of premiers (George Reid of New South Wales, George Turner of Victoria, H. M. Nelson of Queensland, C. C. Kingston of South Australia, Sir Edward Braddon of Tasmania, and Sir John Forrest of Western Australia) held at Hobart on 29 January 1895, Reid moved resolutions of which the principal were (*a*) that a convention, consisting of ten representatives from each colony, directly chosen by the electors, be charged with the duty of framing a federal constitution, and (*b*) that the constitution so framed be submitted to the electors for acceptance or rejection by a direct vote. These being accepted, Reid in October 1895 introduced into the legislative assembly of New South Wales an enabling bill which received the royal assent on 23 December; it included a provision requiring 50,000 affirmative votes before the constitution could be accepted by the colony. New South Wales having led the way, other colonies were not slow to follow. South Australia, under Kingston's leadership, took action as soon as it was clear that New South Wales was in earnest, and dealt with its enabling bill so promptly that it became law on 20 December—three days in advance of the mother-colony. In the South Australian bill no minimum vote was stipulated for. The Tasmanian bill, introduced by Sir Edward Braddon, was passed on 10 January 1896; it required a minimum affirmative vote of 6000—representing about the same proportion of voters as the New South Wales minimum. In Victoria, an enabling act had been introduced by George Turner in December and had passed the assembly almost without opposition, the division on the second reading being 71 to 4; in the council an amendment was made which the assembly regarded as infringing its money powers, and which resulted in a temporary deadlock. In February, however, a second bill was introduced, and became law on 7 March. It required a minimum vote of 50,000. In Queensland, through a difference

between the two houses, the bill was laid aside. In Western Australia an enabling bill was passed, but the constitution was only to be submitted to the people 'if approved by parliament,' and delegates were to be selected by the parliament.

The elections in four colonies were held on 4 March 1897. New South Wales chose as delegates Edmund Barton, G. H. Reid, J. H. Carruthers, W. McMillan, W. J. Lyne, J. N. Brunker, R. E. O'Connor, Sir J. P. Abbott, J. T. Walker, and B. R. Wise. Victoria chose Sir George Turner, John Quick, Alfred Deakin, A. J. Peacock, I. A. Isaacs, W. A. Trenwith, Sir Graham Berry, Simon Fraser, Sir William A. Zeal, and H. B. Higgins. From South Australia came C. C. Kingston, F. W. Holder, J. A. Cockburn, Sir R. C. Baker, J. H. Gordon, J. H. Symon, Sir John Downer, P. McM. Glynn, J. H. Howe, and V. L. Solomon; and from Tasmania Sir Philip O. Fysh, Sir Edward Braddon, Henry Dobson, N. E. Lewis, Nicholas J. Brown, C. H. Grant, Adye Douglas, William Moore, M. J. Clarke, and John Henry.

The first meeting of the convention was fixed for 22 March, and on the 12th the Western Australian parliament amended its enabling act, so as to allow a more speedy selection of the representatives of that colony. They were Sir John Forrest, Sir James G. Lee Steere, George Leake, F. H. Piesse, J. W. Hackett, W. T. Loton, W. H. James, A. Y. Hassell, R. F. Sholl, and J. H. Taylor; but in August Piesse, Loton, Sholl, and Taylor resigned, and were replaced by Henry Briggs, F. T. Crowder, A. H. Henning, and H. W. Venn. This was a notable gathering. It included the premiers of five colonies, the speakers of three, nine other ministers, and 11 ex-ministers.

The convention met at Adelaide on 22 March 1897. Kingston, as premier of the colony, was elected president, and Barton 'leader;' and it was decided not to take the bill of 1891 as the avowed basis of a new constitution, but to start from the beginning. Barton submitted resolutions on the lines laid down by Parkes in 1891, and three committees were then chosen: the constitutional committee was dominated by Barton, Deakin, and Sir R. Baker, but the actual drafting of the constitution was entrusted to Barton, Downer, and O'Connor. On the judiciary committee Higgins, Glynn, and Symon were the leaders. This committee finished its work on 6 April; in the other two the debates were somewhat prolonged, and they did not finish till the 8th. Then the drafting sub-committee prepared a bill, which was submitted to the convention on the 12th. Its framework followed closely that of the bill of 1891. Alterations were made in the basis of representation, in the judiciary, in finance, and in the mode of amending the constitution. During the discussions in committee the most momentous debate was on a clause empowering the senate to amend laws imposing taxation—an extremely important issue, since in the senate all States were to have equal representation, while in the house of representatives (which alone could originate money bills) the more populous States could out-vote the emptier. Thus, if the senate was given power to amend money bills, the less populous States could to some extent control expenditure. Barton, however, pointed out that New South Wales and Victoria would not accept such terms, and it was agreed to retain a compromise arranged in 1891, by which the senate might 'suggest' amendments to money bills, but could not make them. On 22 April the bill was reported to the convention, and adopted the next day; the convention then adjourned until 5 May and was then further adjourned until 2 September, to allow the colonial legislatures time to discuss the bill.

In New South Wales discussion commenced on 5 May, and a number of amendments were suggested; in the legislative council the bill received very hostile treatment. In Victoria and the other colonies the bill was more favourably received but the smaller colonies decided in favour of giving the senate power to amend money bills.

On 2 September the convention assembled in Sydney to consider the proposed amendments, which were 286 in number. As another sitting was inevitable, it was decided to discuss at this one only the larger issues and the debates dealt with the financial problem, the basis of representation in the senate, the powers of the senate with regard to money bills, and the provision for deadlocks between the two houses. On 24 September the convention adjourned, to meet for its final session at Melbourne. The interval between the sessions was seized upon in New South Wales by the opponents of the convention to stem the tide, fast flowing towards a federal union, the force of which they had not recognized before. In June, a bill had been introduced into the assembly by a private member 'to amend the Enabling Act by requiring an affirmative vote at the federal referendum of an absolute majority of all the electors on the roll.' As about 278,000 electors were on the roll, this meant an affirmative vote of some 139,000; there were not sufficient members to go to this extreme, but enough were found to increase to 80,000 the minimum affirmative vote of 50,000 imposed by the enabling act, and on 12 December the bill became law.

On 20 January 1898 the convention assembled at Melbourne for its longest and most important session. The whole bill was thoroughly revised by the drafting committee and thoroughly reconsidered by the convention. During the debate on the financial clauses the famous 'Braddon Clause' (q.v.) was inserted in the bill. On the question of the site of the federal capital, a proposition by Sir George Turner that it should be 'within federal territory' was carried. On 13 March 1898 the convention held its last sitting.

The Referendum of 1898.—The next stage in the history of the bill was to submit it to the electors of the various colonies. In New South Wales formidable opposition was met. J. H. Want resigned his position in the ministry to fight the bill untrammelled. The Sydney *Daily Telegraph* declared against it, and a strong anti-convention bill league was formed. Reid did not declare his policy until 28 March, when he stated that he personally would vote for the bill, but would abstain from any recommendation to the electors, one way or the other. The federalists for their part conducted an active campaign and formed the New South Wales Federal Association. The *Sydney Morning Herald* and the *Evening News* supported the bill. At a late stage the government appointed a commission, consisting of J. Russell French (a banker whose federal views were unknown), Normand MacLaurin (a strong critic of the bill) and Bruce Smith; witnesses were examined, and on 17 May a report was presented which —like Reid's speeches—was claimed by each side

as in its favour. In Victoria the fight was one-sided from the outset, chiefly because of the influence of the Australian Natives' Association. The financial obstacles, too, were less grave than in New South Wales. The anti-bill party was led by H. B. Higgins and Allan McLean. In South Australia the federal representatives united in an appeal to the electors to vote for the bill, and the issue was never in doubt. In Tasmania dissatisfaction was expressed for a time at the provisions limiting the powers of the senate, and fears were expressed that sufficient revenue would not be available for the State under the Braddon clause, but the federalists combated these objections successfully. Western Australia did not take a vote, preferring to await the issue in the other States. The referendum was taken on 3 June 1898 in New South Wales, Victoria, and Tasmania, and on the 4th in South Australia. The result was as follows:—

	N.S.W	Vic.	S.A.	Tas.	Total
For ..	71,595	100,520	35,800	11,797	219,712
Against	66,228	22,099	17,320	2,716	108,363
Majority	5,367	78,421	18,480	9,081	111,349

There was thus a majority for the bill in each of the four colonies. In Victoria, South Australia, and Tasmania the majorities were decisive; but in New South Wales not only was the majority a slender one, but the total affirmative vote fell short by 8405 of the 80,000 minimum required by the act of 1897. In New South Wales therefore, under the provisions of the act, the barely victorious bill was 'deemed to be rejected,' and the whole statuary process, so far as New South Wales was concerned, was at an end. It was recognized by the federal leaders that the next move must be made by Reid. He lost no time; the day after the referendum he suggested to the premiers of the other colonies a conference on proposed amendments, but, as New South Wales was on the eve of a general election, the consensus of opinion favoured delay until the election had been held. On 21 June, before parliament was dissolved, Reid made proposals for modification of the bill, to which Barton and O'Connor objected on the ground that they were practically an ultimatum. At the ensuing election federation became a party question, Reid leading the 'Liberal Federal' party and Barton the 'National Federal' party. Reid defeated Barton, but his parliamentary majority, which had been large, was reduced to about four. Parliament met on 16 August, and Reid introduced resolutions studiously moderate in tone, which the assembly passed with slight additions, the council making more drastic amendments. No attempt was made to harmonize the two sets of resolutions.

On 29 January 1899 the premiers met in Melbourne to consider the suggestions of New South Wales. For the first time since 1895 Queensland was represented at the conference, which lasted until 2 February and resulted in a unanimous agreement. Seven amendments were made in the bill, six at the instance of New South Wales and one at the instance of Queensland. Among them, a provision as to the site of the capital city fixed it definitely in New South Wales, but at least 100 miles from Sydney. The Braddon clause—the temporary retention of which was a general surprise, for it had few friends—was affected by an amendment which placed it, after ten years, at the mercy of the federal parliament. Reid announced that he would support the amended bill with all his power, and on the reassembling of the New South Wales parliament on 21 February introduced a new enabling bill; this provided for a referendum on the amended constitution, at which a simple majority was to decide. The bill passed the assembly with slight opposition, but met with strong hostility from the council; on 30 March parliament was prorogued, and 12 new members were appointed to the council. The hint was accepted, and when parliament met again the enabling bill passed.

The referendum was taken on 20 June. In South Australia a new enabling act was passed in March, and the vote taken on 29 April. Victoria and Tasmania, when the verdict of New South Wales was known, passed enabling acts and fixed 27 July as referendum day. In Queensland an enabling bill was introduced by the premier, which met with strong opposition, but became law on 19 June; the referendum was taken on 2 September. The total results of the voting were as follows:—

	N.S.W.	Vic.	S.A.	Tas.	Qld.	Total
Yes.	107,420	152,653	65,990	13,437	38,488	377,988
No..	82,741	9,805	17,053	791	30,996	141,386
Majority .	24,679	142,848	48,937	12,646	7,492	236,602

The bill was therefore carried in all five colonies.

It will be noted that Western Australia took no referendum. Sir John Forrest's support of the bill slackened, and it was not till July 1899 that the constitution was submitted to the parliament of Western Australia, but amendments proposed in the assembly and the hopeless tangle that occurred in the council prevented the submission of the bill to the people.

The Final Stage.—The next step was to pass through the various legislatures addresses praying that the constitution should be passed into law by the imperial parliament. This done, on 22 December 1899 Joseph Chamberlain (then secretary of state for the colonies) telegraphed his hope that a delegation from the federating colonies would visit England and be present when the Commonwealth bill was submitted to the imperial parliament. It was therefore arranged that a delegation should be sent, consisting of Edmund Barton, Alfred Deakin, J. R. Dickson (of Queensland), and C. C. Kingston, and that they should be joined in London by Sir Philip Fysh. It was agreed that the delegation should unitedly urge the passage of the bill without amendment, and act as one man in explaining legal or constitutional questions. The government of Western Australia expressed a desire to be represented, and (with the concurrence of the secretary of state) despatched S. H. Parker, as its delegate.

Towards the middle of March 1900 the delegates arrived in London. Barton was appointed spokesmen, and on 15 March they had their first informal conference with Chamberlain and the crown law officers. The chief objection was made to clause 74, which restricted the right of appeal to the privy council. On 27 March W. P. Reeves, agent-general for New Zealand, informed the colonial office that he had been appointed a delegate, and a few days later forwarded a memorandum of amendments desired by his colony. On the 30th the Western Australian delegate also forwarded a memorandum asking that Western Australia should be allowed for five years after the imposition of the federal tariff, to receive the customs duties in force

at the passing of the Commonwealth act. If this amendment were made, he said, Western Australia would probably enter the Commonwealth.

Then followed conferences, memoranda, and minutes, through all of which the delegates from eastern Australia steadily urged that the bill should be passed as adopted by the five colonies. Chamberlain, on the other hand, was—or the law officers who advised him were—anxious to alter the clause restricting the right of appeal to the privy council; he referred the matter over the delegates' heads to their premiers, who conferred in Melbourne from 19 to 21 April and replied that the mandate of the Australian people was to seek the enactment of the bill in the form in which it was adopted by the people. On 27 April Chamberlain cabled to Western Australia urging the colony to join the Commonwealth as an original State, and was told in answer that parliament had been summoned for 17 May, and an enabling bill would be immediately introduced. On 14 May Chamberlain introduced the Commonwealth Bill into the house of commons; the second reading was moved on 21 May, and Chamberlain announced that a settlement had been arrived at with the delegates in regard to the form of proposed amendments. On 16 June the privy council appeals clause (74) was remodelled in the form in which it now stands in the constitution. In the house of lords the bill was read a first time on 26 June; the second reading was moved on the 29th; on 3 July the bill passed through committee without amendment, and on the 5th was read a third time and passed. On the 9th the Queen gave her assent to the bill, signing the commission, declaring her assent to the bill in duplicate at the delegates' request, and gave one of the copies, as well as the pen, inkstand, and table she had used, to be preserved in the federal parliament buildings.

In the meantime, the parliament of Western Australia had taken action. On 13 June an enabling bill, on the lines of those passed by the other colonies, was assented to, and referendum day fixed for 31 July. The result of the vote was as follows:—Yes 44,800; No 19,691; Majority for bill 25,109. On 21 August both houses passed the necessary addresses to the Queen. The proclamation by Her Majesty of the Commonwealth had been delayed until Western Australia had arrived at a decision, and it was now decided to call the Commonwealth into being on 1 January 1901. On 17 September 1900, therefore, Her Majesty signed a proclamation in the following terms:—

> Whereas by an Act of Parliament passed in the Sixty-third and Sixty-fourth Years of our reign intituled "An Act to constitute the Commonwealth of Australia" it is enacted that it shall be lawful for the Queen, with the advice of the Privy Council, to declare by Proclamation, that, on and after a day therein appointed, not being later than One year after the passing of this Act, the people of New South Wales, Victoria, South Australia, Queensland and Tasmania, and also if Her Majesty is satisfied that the people of Western Australia have agreed thereto, of Western Australia, shall be united in a Federal Commonwealth under the name of the Commonwealth of Australia.
>
> And whereas We are satisfied that the people of Western Australia have agreed thereto accordingly.
>
> We therefore, by and with the advice of Our Privy Council, have thought fit to issue this Our Royal Proclamation and We do hereby declare that on and after the first day of January One thousand nine hundred and one, and people of New South Wales, Victoria, South Australia, Queensland, Tasmania and Western Australia shall be united in a Federal Commonwealth under the name of the Commonwealth of Australia.
>
> Given at Our Court at Balmoral this Seventeenth day of September, in the Year of our Lord One thousand nine hundred and in the sixty-fourth year of our reign.
>
> GOD SAVE THE QUEEN.

On 14 July 1900 it had been officially announced that the first governor-general of the Commonwealth would be the Earl of Hopetoun, and the official appointment was made on 21 September. An announcement was made at the same time that the Duke and Duchess of York would visit Australia early in 1901 and that the Duke would be commissioned by Her Majesty to open the first session of the federal parliament in her name.

The history of the movement towards federation is fully told in Quick & Garran's *Annotated Constitution of the Australian Commonwealth* (Sydney, 1901). The later campaigns are described well, but with some bias, in Wise's *Making of the Australian Commonwealth* (London, 1913); and the constitution is thoroughly examined and annotated both in the Quick and Garran volume and in Harrison Moore's *Constitution of the Commonwealth of Australia* (2nd edition Melbourne, 1910). A good deal of light is thrown on the early stages of the 1883-1897 campaign in Sir Henry Parkes's *Fifty Years in the Making of Australian History* (London, 1892).

Fellows, THOMAS HOWARD (1823-1878), son of a Hertfordshire solicitor, was born in 1823, educated at Eton, trained for the law under Tompson Chitty, and called to the bar in 1852. Almost immediately he migrated to Victoria, was admitted to the local bar, and in 1855 entered politics as a member of the old legislative council. In June 1856 he succeeded Robert Molesworth as solicitor-general in the first Haines ministry; later in the year he was returned by St. Kilda to the new assembly; and in the February following he took W. F. Stawell's place as attorney-general when the latter was made chief justice. In the second Haines ministry (1857-8) he was again solicitor-general; when Haines was defeated, he left the assembly for the council and in that body represented the Nicholson ministry from October 1859 to November 1860; he was postmaster-general in the first McCulloch ministry from October 1863 to March 1864, but then resigned because his policy differed entirely from that of his colleagues, and in the succeeding years opposed bitterly McCulloch's attempts to 'tack' tariff and other clauses to the annual appropriation bill. This three-years' fight—during which Fellows was more than once approached to form a ministry, and, vacating his seat in the council, was re-elected by St. Kilda to the assembly—ended in the formation of the two-months' Sladen ministry, in which Fellows was minister for justice. From July 1868, when that ministry came to an end, until February 1872 he held his assembly seat, devoting much time (as always) to his profession, in which he attained eminence; he was then made a judge of the supreme court, and remained on the bench until his death on 8 April 1878.

Felton, ALFRED (1831-1904), born at Maldon in Essex on 8 December 1831, was attracted to Victoria by the news of the great gold-rush and reached Melbourne in 1853 to open in the business of wholesale druggist and

general merchant. In 1866 he joined F. S. Grimwade in founding the drug-importing and manufacturing firm of Felton, Grimwade & Co., and in later years acquired much pastoral property. Never married, he employed his constantly increasing wealth mainly on charitable and artistic objects, and, when he died on 8 January 1904, left an estate of (roughly) £400,000 to be applied to these objects in equal shares. The terms and results of the Felton bequest for art purposes, through which the national gallery of Victoria in 1905-22 acquired nearly £200,000 worth of pictures and sculpture, are discussed under ART GALLERIES. A similar amount has been distributed among charities.

Ferguson, SIR JAMES (1832-1907), born in Edinburgh on 14 March 1832 and educated at Rugby and Oxford, entered the army as ensign in 1851, and served with his regiment (the Grenadier Guards) in the Crimean war until May 1855, when he returned to Scotland to represent Ayrshire in the British parliament. After a somewhat chequered parliamentary career he became under-secretary to the India office in 1866, and took the same post in the home office in 1867, winning the reputation of an excellent and helpful subordinate. In 1868, when Disraeli succeeded Lord Derby as premier, Fergusson accepted the governorship of South Australia, and reached Adelaide on 16 February 1869. His term of office there included little of importance that a constitutional governor could greatly influence, but he gave all possible aid to the establishment of the overland telegraph line to Port Darwin and of through communication with England by this means. Leaving South Australia in 1873, he was for a short time (14 June 1873 to 3 December 1874) governor of New Zealand, but in 1875 returned to England and unsuccessfully attempted to re-enter parliament. In 1880 he succeeded Sir R. Temple as governor of Bombay, where he had real power, and used it to improve the condition of the agricultural population and avert famines, besides developing the port of Bombay and encouraging education. Politics, however, were his hobby; in 1885 he hurried home to resume his parliamentary career, gaining the seat of North-east Manchester in November and holding it for 20 years, during which he was under-secretary to the foreign office (1886-91) and postmaster-general (1891-2). Business affairs in 1907 drew him to Jamaica, where he was killed by the fall of a building during the earthquake of 14 January in that year. (P.C., 1868; K.C.M.G., 1874; C.I.E., 1880; G.C.S.I., 1885.)

Fern-bird. See SCRUB-WRENS.

Ferns. The fern-flora of Australia follows the flow of the recognized tropical and antarctic life-streams (see ZOOGEOGRAPHY), and shares in a still wider distribution, having Pacific and even European affinities. The richest fern-region of the Commonwealth is the tropical north-eastern area of Queensland.

In discussing ferns we must employ many technical terms that are unfamiliar to the flower-lover. Thus the plant itself is the spore-bearer or sporophyte, and a small film (prothallium), developed from the spore, is the gametophyte or bearer of the generative organs. The root of a fern is called the rhizome, the leaf-stem the stipes, and the leafy growth above the stipes the frond—whose divisions, if any, are successively pinnae, pinnules, and lobes or segments. The main rib of a frond is the rhachis; the rib of a pinna is the secondary rhachis; the ribs of the ultimate divisions are costae and costules. The spores are grown in a sporangium; a cluster of sporangia is a sorus; the sori are frequently

Sporangia of (a) *Polypodium*, (b) *Cyathea* (showing spores), (c) *Schizoea*.

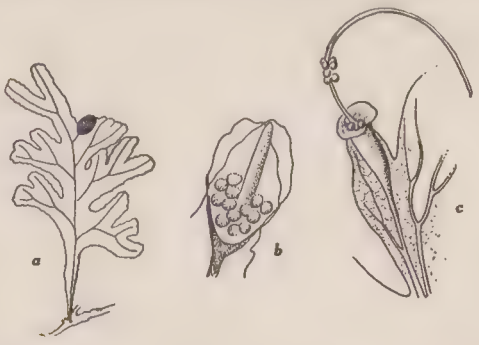
covered or surrounded by a membranous indusium. The part of a fern which carries the sorus is the receptacle.

The classification adopted in this article is as follows:—

Class I. FILICALES.
  Series i. Leptosporangiatae (each sporangium developed from a single cell).
    Sub-series 1. Eufilicineae (ferns proper).
      Families Hymenophyllaceae, Cyatheaceae, Polypodiaceae, Parkeriaceae, Gleicheniaceae, Platyzomataceae, Schizaeaceae, Osmundaceae.
    Sub-series 2. Hydropteridineae (water-ferns).
      Families Salviniaceae, Marsileaceae.
  Series ii. Eusporangiatae (each sporangium developed from a group of superficial cells).
    Families Marattiaceae, Ophioglossaceae.
Class II. LYCOPODIALES.
  Series i. Eligulatae, family Lycopodiaceae.
  Series ii. Ligulatae, family Selaginellaceae.
Class III. ISOETALES, family Isoetaceae.
Class IV. SPHENOPHYLLALES, family Psilotaceae.

This article deals with Class I only: for the other classes see LYCOPODIALES and PSILOTACEAE.

The main distinction of the Hymenophyllaceae (Filmy Ferns) lies in the nature of the receptacle, which is a hair-like development within a cup-shaped or vase-shaped indusium. The sporangia are sessile. There are two genera, *Hymenophyllum* and *Trichomanes*, the former having a more or less deeply two-valved indusium, the latter an indusium that is vase-shaped. The



(a) Frond and (b) fruit of *Hymenophyllum babindae*; (c) indusium of *Trichomanes venosum*.

surfaces of the sporangium in *Hymenophyllum* are composed of numerous regular cells, whereas in *Trichomanes* they are few and irregular. *Hymenophyllum* has about 15 known species, mainly in southern Australia, though a few

beautiful species have been recently added from the tropics. *Trichomanes*, on the other hand, is found chiefly in northern Queensland, where there are 25 species, but five or six of these extend into New South Wales.

Of the tree-ferns (Cyatheaceae) three genera are represented in Australia, *Dicksonia*, *Cyathea* and *Alsophila*. In *Dicksonia* the sorus is intramarginal at the apex of a vein, and the indusium two-valved, the outer valve consisting of a modified lobe of the frond. *D. antarctica*, a magnificent tree-fern, is common in the southern States and in New Zealand, and extends north to southern Queensland. *D. Youngiae* is found in the northern half of New South Wales, and as far north as the Bellenden Ker range in Queensland. *Cyathea* carries its sori at the back or at the forking of veins; the indusium is distinct and globose, quite enclosing the sorus when young, but afterwards bursting downwards irregularly and disappearing, or becoming more or less cup-shaped. *C. medullaris* and *C. Cunninghami* are found in Victoria and Tasmania. *C. Lindsayana* (from Mount Lindesay in Queensland) and *C. arachnoidea* (from Rockingham Bay in northern Queensland) have been collected once only. The globose sori of *Alsophila* occur on the backs or in the forks of veins: the indusium, in the few cases where it exists at all, is spurious and minute. This is the most characteristic Australian genus: *A. australis*, the southern species, extends well to the northwards; *A. Cooperi* and *A. Leichhardtiana* are of the central zone, the former reaching the tropics: *A. Rebeccae*, *A. Baileyana* (sometimes reckoned a variety of *A. Rebeccae*) and *A. Robertsiana* belong to northern Queensland. It is doubtful whether *A. excelsa* occurs in Australia, and *A. Loddigesi* is a doubtful species. No tree-ferns have yet been recorded from Western Australia.

By far the largest family of ferns is the Polypodiaceae, characterized by stalked sporangia with an incomplete vertical ring. The family includes twelve tribes—Woodsieae, Dryopterideae, Aspidieae, Oleandreae, Davallieae, Asplenieae, Blechneae, Pterideae, Vittarieae, Polypodieae, Acrosticheae, and Platycerieae.

The small tribe Woodsieae is represented in Australia by *Cystopteris fragilis* (Brittle Bladder-fern), found in cold regions in many parts of the world. The indusium is attached below the sorus and inflated over it. This little fern has been recorded from Tasmania, Victoria, and the Snowy Mountains in New South Wales.

The Dryopterideae, whose fronds somewhat resemble the leaves of an oak, include all ferns ascribed in Christensen's *Index* to the genus *Dryopteris*, both the indusiate and the ex-indusiate species. The genus *Dryopteris* in our classification includes indusiate species with free veins: *D. decomposita* is a typical species. *Nephrodium* includes indusiate species in which the veins are more or less united, especially alongside the midrib: typical species are *N. parasiticum* and *N. gongylodus*, the latter apparently the only *Nephrodium* that extends to South and Western Australia. *Phegopteris* has free veins, but the indusium is either absent or disappears early: typical species are *P. punctata* (which in Australia exists mainly as the variety *rugosula*) and *P. Queenslandica*, which extends over southern Queensland and northern New South Wales. *Goniopteris* resembles *Nephrodium* in venation, but has an early-disappearing indusium or none at all. All the species, including the handsome *G. urophylla*, belong to the tropical north. In *Meniscium*, which is represented in northern Queensland by the rare *M. triphyllum*, the veins unite, and the sori (which lack an indusium) are often confluent at the junction of the transverse veinlets: they are also known to run along the ex-current veinlets.

Nephrodium parasiticum.

The Aspidieae comprise the genera *Aspidium*, *Polystichum* and *Leptochilus*. *Polystichum* is characterized by free veins, a circular (rarely slit) indusium attached at the centre, and a coriaceous or sub-coriaceous texture. Typical species are *P. adiantiforme* (also known as *Aspidium capense*) and *P. aculeatum*, both widespread. *P. hispidum*, a beautiful species, is found in Tasmania and Victoria, and on Mount Wilson in the Blue Mountains of New South Wales. The indusium of *Aspidium* resembles that of *Polystichum*, but the veins are reticulated—that is, they form meshes (areoles), with free veins within the areoles. The only Australian species is the handsome *A. Mucllcri*. In *Leptochilus* the indusium is elongated along the rhachis, and sometimes overlaps it, the sori ultimately covering the underside of the fertile part of the frond; usually some fronds are fertile, others sterile. The three Australian species are tropical—*L. cuspidatus* has a wide tropical range, but *L. neglectus* and *L. Taylori* (which may be only a variety of *cuspidatus*) are indigenous to northern Queensland.

Polystichum aculeatum.

The Oleandreae comprise a single genus, *Oleandra*, with round sori and a reniform indusium; the sori are placed in a row near the base, or below the centre, of the compact free veinlets. The beautiful *O. neriiformis*, which has a wide tropical range, is found in northern Queensland.

In the Davallicae the indusium is attached at the bottom, or at bottom and sides (like a half-goblet or a swallow's nest), and open at the top; the sorus is at the apex of a vein. In *Nephrolepis* the pinnae are jointed to the rhachis, the fronds are not jointed to the rhizome, and the indusium is fastened at the base only. *N. exaltata* has been recorded from north-western Australia; *N. cordifolia* extends from the tropics well into New South Wales; *N. acutifolia* (also known as *Lindsaya lanuginosa*) is a beautiful fern with a wide tropical range that is found in the scrubs of northern Queensland. In *Hu-*

(a) *Nephrolepis cordifolia* (b) *Microlepia speluncae.*

mata the pinnae are not jointed to the rhachis, the fronds are jointed to the rhizome, and the indusium is fastened at the base only. *H. repens*, a widespread tropical fern, is found in the gullies of the Bellenden Ker range, where also *Leptolepia tripinnata* (whose fronds are not jointed to the rhizome) is endemic. In *Davallia* the indusium is attached on three sides, and the fronds are jointed to the rhizome. *D. pyxidata* is the common Hare's-foot Fern, extending from northern Queensland into Victoria; *D. dubia* (Mountain Bracken) occurs throughout Australia; tropical species are *D. denticulata*, *D. solida* and *D. epiphylla* (recorded from Cairns). *Microlepia* has the *Davallia* indusium, but the fronds are not jointed to the rhizome; *M. speluncae*, a widespread tropical species, occurs in northern Queensland. In *Dennstaedtia* the indusium is a bi-valvular flattened scale, the outer valve not belonging to the leaf-margin; the sori are submarginal at the base of the sinus. *D. davallioides*, a beautiful fern, extends from Tasmania to southern Queensland. In *Schizoloma* the sori are often confluent at the margin, and in the Australian species the nerves are reticulated: *S. ensifolium* occurs in northern Queensland in a bewildering diversity of forms. In *Lindsaya* the marginal or submarginal sori unite the ends of two or more veins, and the indusium is double, the outer valve consisting of the modified edge of the leaf-segment; in the pinnae the basi-scopic half is scarcely developed. This genus is represented in Australia by several delicate species, most found in northern Queensland—but *L. linearis* occurs in all the States.

Lindsaya linearis.

In the Asplenieae the sori are more or less elongated and linear, usually parallel with the side-nerves; the indusium opens lengthwise. *Athyrium* has fine-celled scales at the base of the stipes, short sori, one on a nerve, and an indusium often slightly curved and sitting on the nerve; *A. umbrosum*, a fern known in the islands of the Atlantic, occurs in the varieties *australe* and *tenerum*, which were described by Robert Brown under a separate genus *Allantodia*. The small *A. humilum* is found on the Ellenborough River west of Port Macquarie in New South Wales. In *Diplazium* sori occur two on a nerve, at least near the base of pinnules; its Australian species are mostly tropical, but *D. latifolium* extends southwards into New South Wales. In *Asplenium* the scales are strong-celled, the sori one on a nerve, and the indusium opens inwards: this genus is well represented in Australia. *A. bulbiferum* (Hen-and-chicken Fern) and *A. flaccidum* range from Tasmania into southern Queensland, *A. nidus* is the Bird's-nest Fern, and *A. adiantioides* is remarkably graceful. *Pleurosorus* lacks an indusium: *P. rutaefolius* (Rue Spleenwort) is widespread in extra-tropical Australia, especially among rocks and on dry ridges.

The Blechneae are closely allied to the Asplenieae, and F. O. Bower has proposed to make one family of the two: for the present, however, they may be treated as separate, the distinctive character of the Blechneae being that the sori are borne on a nerve-anastomosis parallel with the midrib. In *Blechnum* the sori are confluent and have an indusium; *B. cartilagineum*, with decurrent pinnae, is the typical species, and is common in the eastern States. *B. serrulatum* and *B. orientale* are northern, and *B. Whelani* is found in the Bellenden Ker range. All these have uniform fronds. In a section with dimorphic fronds (sometimes classed as a separate genus, *Lomaria*) the typical species are *B. Patersoni* and *B. discolor*, both found in most of the States. *B. capense*, which is variable and almost cosmopolitan, is frequently found with uniform fronds, and its variety *Gregsoni*, from the Mount Wilson district in New South Wales, is very rarely dimorphic. In *Stenochlaena* the confluent sori lack an indusium, and the fronds are di- or tri-morphic: the genus is represented in Australia by two fine climbing ferns, *S. palustris*—found in swamps and on the edge of lakes in northern Queensland—and *S. sorbifolia*, a pan-tropical species whose variety *leptocarpa* occurs in northern Queensland scrubs. The sori of *Doodia* are separate, in one or more rows. This genus comprises two well-defined groups, one with pinnatifid fronds, the segments towards the base being adnate to the rhachis, and the lowest pair occasionally free; in the other group the fronds are pinnate—at least in the lower half. To the first group belong *D. aspera*, widespread in Australia, *D. blechnoides* (which differs from *D. aspera* in having its lower pinnae less strongly shortened and its sori nearer the midrib), and *D. heterophylla* from the scrubs along the coastal railway line in southern Queensland. The second group is represented by *D. caudata*, which ranges from Tasmania to tropical Queensland.

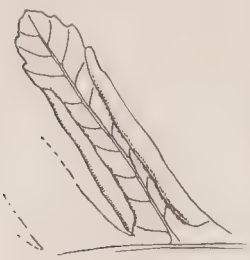
The Pteridеae include ferns that show a more or less wing-like arrangement of the sori. There are four sub-tribes, and further complicated subdivisions, but only the Australian species need be mentioned here. *Syngramma pinnata* and *Gymnopteris Muelleri* are found in northern Queensland: *Anogramma leptophylla* has been recorded from all the States except Queensland; *Gymnopteris Reynoldsi* is endemic near Mount Olga in the Northern Territory; *Peltaea falcata* (Sickle-fern) is widespread in Australia, growing usually in damp places, but in New South Wales and southern Queensland is often replaced by its variety *nana*, which grows among rocks. *P. paradoxa* is limited to New South Wales. The beautiful *Doryopteris concolor* is found in Queensland and northern New South Wales. *Notholaena distans* is hairy, *N. Browni* woolly; both range through all the States, as does *Cheilanthes tenuifolia*. *Hypolepis tenuifolia*, another widespread fern, is easily recognized by its solitary recurved marginal indusium. *Neurosoria pteroides*, which occurs in Queensland and the Northern Territory, is a

Anogramma leptophylla.

Peltaea paradoxa.

bipinnate form, with linear pinnae crowded with sporangia; the modified crenulate margins recurve until, in dried specimens, opposite edges often meet over the rhachis. *Plagiogyria euphlebia,* a widespread tropical species, has been recorded from Rockingham Bay in northern Queensland.

Two of the sub-tribes of Pterideae contain well-known ferns. The Adiantinae are the maidenhair ferns, all belonging to the genus *Adiantum*; *A. aethiopicum* is the cosmopolitan form, *A. formosum* the Giant Maidenhair, and *A. affine, A. hispidulum,* and the very delicate *A. diaphanum* occur in eastern Australia. *A. hispidulum* has also been recorded from the George Gills range in the Northern Territory. The Pteridinae include, besides *Histiopteris incisa* (found in all the States except Western Australia) and several species of *Pteris,* the cosmopolitan Bracken-fern (*Pteridium aquilinum*), which in Australia usually occurs in the variety *esculentum.* The Vittarieae are mainly tropical. Their sori are either



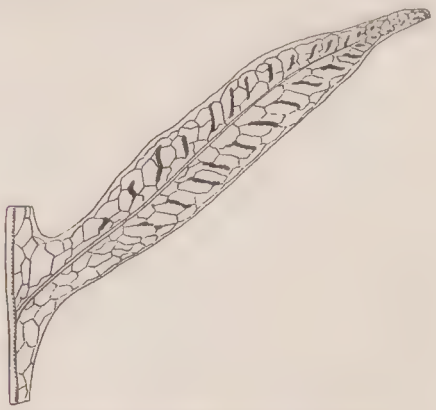
Pteris tremula.

marginal or carried on nerves more or less parallel to the midrib; the epidermis carries thick-walled spicular cells. Two species of *Monogramma* have been found in northern Queensland, *M. dareicarpa* in the Bellenden Ker range and *M. paradoxa,* var. *angustissima,* at Rockingham Bay and on the Atherton tableland. *Vittaria elongata,* a grass-like fern, ranges from northern Queensland into New South Wales; *V. wooroonooran,* a short-leaved species, occurs on Bellenden Ker. *Antrophyum reticulatum* and *A. callifolium* also occur in northern Queensland.

Polypodium Gordoni.

Antrophyum reticulatum.

An easily recognizable tribe is the Polypodieae, with roundish or elongated sori, no indusium, nervation pinnate, and stipes jointed to the rhizome. *Hymenolepis spicata,* with its unique tail-like sorus at the tip of the frond, occurs in northern Queensland. Of *Polypodium* there are several forms: in one—represented by *P. cucullatum* (Cowled Polypody), a rare tropical species—the upper pinnae which bear the sori are hollowed; in another the fronds are once divided, with pinnate nervation (most of the species are tropical, but *P. grammitidis* belongs to southern Australia); in a third (with two tropical species) the side-nerves are joined; in a fourth they are richly branched and form a close, irregular network—nearly all these species are tropical, but *P. Browni* extends from northern Queensland into New South Wales, and *P. scandens* and *P. pustulatum* (Scented Polypody) are southern ferns with a good range northwards. A fifth, characterized by simple fronds with free veins, is represented by *P. australe,* widely distributed, *P. Hookeri,* a tropical species covered with rich brown hairs, and *P. albosetosum,* found on Bellenden Ker. In *P. amplum,* which adorns tree-stems on the coast of northern Queensland, and *P. Selliguae,* found in a similar



Polypodium Selliguae (var. *Sayeri*).

position inland, the sori are more or less confluent, and form a continuous row parallel to the side-nerves. The genus *Cyclophorus* includes *C. serpens,* var. *rupestris, C. confluens, C. acrostichoides* (tropical), and *C. spicatus,* found in the Tambourine range in southern Queensland. *Drynaria rigidula* occurs throughout Queensland, and has been recorded from the Blue Mountains of New South Wales. *D. quercifolia,* a widely spread tropical species, is found in Australia only in the northern Queensland variety *sparsisora.*

The sporangia of the Acrosticheae occupy the whole under-side of the fertile frond. *Elaphoglossum conforme,* a pan-tropical species with (usually) undivided leaves, occurs rarely in northern Queensland. *Acrostichum aureum,* a worldwide tropical and subtropical fern, is found all over tropical Australia and in the north-coast swamps of New South Wales.

The last tribe of the Polypodiaceae, the Platycerieae, comprises certain well-known and dis-

tinct species. *Platycerium grande* (Staghorn) ranges from northern Queensland into New South Wales, and *P. bifurcatum* (Elkhorn) from mid-Queensland to southern New South Wales.

The Parkeriaceae are a small family represented in Australia by the unique *Ceratopteris thalictroides*, a denizen of tropical swamps. It has been found in north-western Australia and in Queensland, where its southern limit appears to be Moreton Bay.

In the Gleicheniaceae the sporangia open vertically and are surrounded by a broad transverse ring; there is no indusium. *Gleichenia linearis*, a pantropical species, has been found in New South Wales; *G. flagellaris* occurs in the eastern States as far south as Braidwood. In this genus F. von Mueller included Robert Brown's *Platyzoma microphyllum*, a tropical fern which has sorely puzzled systematists. Its long, narrow, pinnate leaves side by side with short filiform ones, and its broad, variable annulus (vertical, oblique, or horizontal, and almost always irregular and broken) make it so unique among ferns that we prefer to place it in a family by itself, the Platyzomataceae.

Platyzoma microphyllum.

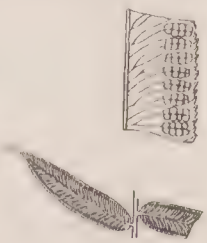
In the Schizaeaceae the sporangium is crowned by a ring like an operculum, which splits into two valves. *Schizaea* has bilateral spores, an upright rhachis, and leaves in several rows. In *S. rupestris* (limited to the neighbourhood of Sydney and the Blue Mountains) and *S. fistulosa* (found in all the southern States) the leaves are undivided: *S. bifida* occurs throughout the Commonwealth; *S. dichotoma*, a widespread tropical species, is found in the Northern Territory, Queensland and New South Wales, usually near the coast. *Lygodium* is a genus of climbing ferns, tropical and subtropical. *L. reticulatum* (known in Fiji as the God-fern) is plentiful in northern Queensland; *L. flexuosum*, also common there, is sometimes confused with *L. japonicum*, which probably does not exist in Australia; *L. scandens*, usually found in swamps, ranges throughout tropical Australia and has been found on the northern rivers of New South Wales.

In the Osmundaceae the sporangia open across the apex into two valves; the annulus is either lacking or very obscure. *Todea barbara*, widespread in Australia, is a large fern, thick-stemmed, with rigid light-green fronds; the pinnae stand at a sharp angle, the pinnules are decurrent, and the sporangia are densely clustered on the low pinnules and often cover them. *Leptopteris Fraseri*, probably the most delicately beautiful fern in Australia, is plentiful in the glens of the Blue Mountains, and ranges from the Clyde River in southern New South Wales to Bellenden Ker in northern Queensland; it is less robust than *Todea*, dark-green in colour, and its sporangia are smaller and fewer.

Of the water-ferns (Hydropteridineae) Australia has two families—the Salviniaceae, which are floating plants, and the Marsileaceae, which grow in marshy or inundated ground, to which their horizontal rhizomes are attached by means of rootlets. All these water-ferns have their sori at the roots, and the sporangia bear two kinds of spores—some yielding a single 'megasphore' which bears a female prothallium, others numerous 'microspores' from which come the male prothallia. The Salviniaceae are represented in Australia by *Azolla rubra* and *A. pinnata*, plants closely set with tiny leaves and with many true roots hanging down in the water. Of the Marsileaceae Australia has also two genera: *Marsilea Drummondi* is the well-known nardoo (q.v.), *Pilularia* has needle-like leaves. *P. novae-hollandiae*, the Australian form, has been sometimes confused with the European *P. globulifera*.

Marsilea.

The Marattiaceae include two genera of remarkable ferns in which the sporangia lie side by side in a boat-shaped sorus (synangium) and open by a slit down one side. In *Marattia* the synangium opens lengthwise and the sporangia are imbedded inside the two valves: *Marattia oreades is* found on Bellenden Ker, *M. fraxinea* (var. *salicina*) is plentiful in the coastal scrubs of northern Queensland. In *Angiopteris* the synangium opens crosswise, separating the sporangia by a thick wall; *A. evecta* is a magnificent tropical fern, sometimes 24-25 feet long and 13-14 feet across.



Angiopteris evecta.

The Ophioglossaceae are ferns whose sporangia grow in clusters on a special spike that springs from the sterile part of the frond; they are deeply two-valved, opening down the side almost to the base. *Ophioglossum pendulum* (Ribbon-fern) ranges from northern Queensland to the northern rivers of New South Wales; *O. vulgatum* (Snake's-tongue Fern) is found throughout Australia, but not in the typical form, so that some writers credit Australia with seven separate species. *Helminthostachys zeylanica* is rarely found in northern Queensland. *Botrychium ternatum* occurs in all the States except Western Australia; the Australian form was erected by Robert Brown into a separate species, *B. australe*. *B. lunaria* has been recorded from New South Wales, Victoria, and Tasmania.

Ophioglossum pendulum.

Besides the standard works by Labillardière, Brown, Hooker, Bentham, Christensen, Leuerssen, and D. H. Campbell, the following botanists have published handbooks on Australian ferns

or contributed papers about them to Australian scientific journals:—F. von Mueller, Domin, Moore, Maiden and Betche, Ewart, and Watts. Bailey has dealt with the ferns of Queensland, Turner with those of New South Wales, Pitcher with those of Victoria, Rodway with those of Tasmania, and Tate with those of South Australia. W.W.W.

Field, BARRON (1786-1846), born in London on 23 October 1786, probably educated at Christ's Hospital, trained for the law and called to the bar at the Inner Temple on 23 June 1814, had by that time made himself a small reputation among the literary companions of Charles Lamb and Leigh Hunt; he was also theatrical critic of *The Times*, and a contributor to the *Quarterly Review*. His career at the English bar was short and unsuccessful, and in 1816 he applied for and obtained a position as judge of the supreme court of New South Wales in succession to Jeffery Bent (q.v.). Reaching Sydney on 24 February 1817, he administered justice there until 4 February 1824; then he returned to England on a pension of £400 a year, and obtained the position of advocate-fiscal (i.e. crown prosecutor) for Ceylon, and dropped it in February 1829 to take the chief-justiceship at Gibraltar. In 1835 he resigned, returned to England once more and abandoned the law altogether, dying at Torquay on 11 April 1846.

Of Field's legal career little need be said. At the outset of it Macquarie took a great fancy to him and praised his 'mild, modest and conciliating manners,' and Biggs approved his conduct of affairs whole-heartedly; but he came into collision with Brisbane over the appointment of John Macarthur to the magistracy and over the Douglass case, and in 1824 Brisbane accused him of official discourtesy, slander, and making himself 'the head of a faction . . . . who seemed guided by no moral restraints in order to accomplish their ends.' Field's recall, while obviously caused by the necessity of entrusting the new supreme court (created by the act of 1823) to a lawyer of great ability and learning, may have been also partly due to the incessant friction between him and the governor. Of his term at Gibraltar nothing is known except that Disraeli in his Beau Brummell stage considered him 'noisy, obtrusive, jargonic'—an exaggerated form of the verdict frequently passed by conceited young men on elders perhaps rather too fond of laying down the law.

But Field's chief claim to remembrance lies in his writings, not so much for their intrinsic value as because one section of them pioneered Australian literature and science, and another forms no inconsiderable part of the critical literature inspired by Charles Lamb. Unfortunately he began his Australian work with the publication of a slim volume of verse, of which the less said the better for his credit—though he was proud of it, issued two editions in New South Wales (1819 and 1823), and republished the second edition in London as part of his *Geographical Memoirs on New South Wales* (1825). This was a collection of articles some of which he had originally written for the *London Magazine* during 1822-5. Not all were Field's, but he must have the credit of first publishing Oxley's report of his Moreton Bay voyage, Pamphlett's of his shipwreck, Allan Cunningham's of his discovery of Pandora Pass, and several monographs on the geology, botany, meteorology, ethnology, and maritime geography of New South Wales, and the astronomy of the southern hemisphere, all by the recognized local authorities on their subjects. It is unjust to the zealous and patriotic editor of these memoirs to remember him solely by a dozen pages of poor verse. Field also wrote a preface for the *Memoirs* of Hardy Vaux (q.v.). After his return from Gibraltar he devoted himself mainly to the study of Elizabethan drama, editing five plays of Heywood's between 1842 and 1846; he wrote a good memoir of Charles Lamb (1836), and wanted to write a *Life* of Wordsworth, but the poet would not allow it. Lamb reviewed his verse in the *Examiner*, addressed to him the essay 'Distant Correspondents,' and embalmed him as B.F. in 'Mackery End.' W.J.

Fig, the popular name of several species of *Ficus*, a large genus of the family Urticaceae, widely spread over the tropical and subtropical regions of the world, but most abundant in Malaysia. Sixty species are indigenous to Australia, chiefly to its eastern areas; but *F. platypoda* extends to Western Australia, and *F. orbicularis* is found in South Australia. *F. rubiginosa* (Port Jackson or Illawarra Fig—also Rusty Fig, from the colour of the under-side of its leaves) and *F. macrophylla* (Moreton Bay Fig) are useful fodder-plants, cattle and horses eating the twigs, leaves, and fruit with zest; the aborigines eat the fruit, and use the fibre obtained from the roots—which is very durable—to make their scoop fishing nets. Both these species are often planted as ornamental trees to provide shade or form an avenue. *F. rubiginosa* is found chiefly in the coastal districts, but extends as far west as Narrabri and northward into Queensland. These trees often develop huge projecting buttresses at the base, whose interspaces are sometimes ingeniously converted by settlers into shelters for animals. In brush forests the figs may originate either from seed or from the aerial roots of another fig, which attach themselves to the bark of a neighbouring tree. It is not uncommon to see a huge tree completely enveloped in these aerial roots, the fig finally strangling its host and taking its

Port Jackson Fig.

place. *F. macrophylla* extends from the northern rivers of New South Wales into Queensland. *F. glomerata* (Clustered Fig) extends from Queensland and northern Australia to India; it is a large tree, with fruits which hang in clusters, red when ripe, along the trunk and limbs, and are used as a food by natives in both Australia and India. *F. Henneana* is known as the Deciduous Fig; but the trees are bare for a few weeks only, the new leaves showing very soon. The ripe fruits are ornamental, red to purple, spotted with white. This species, originally described from specimens collected at Booby Island in Torres Straits, was found in 1902 on the banks of the Port Hacking River in New South Wales. It is a handsome tree, easily propagated from seed. *F. stephanocarpa* (Rough-leaved Fig) is a slender tree (15-25 feet) ranging from southern New South Wales into Queensland; it is the 'noomaii' of the Rockhampton aborigines, who eat the fruits—which turn black when ripe. In Fiji the leaves of this species are used for serving food, and in the Clarence River district of New South Wales as a substitute for sand-paper. *F. platypoda*, a small but robust tree, has edible fruits which explorers have described as very good. It has a soft, strongly fibrous wood. *F. columnaris* is the Lord Howe Island 'banyan;' old specimens cover large areas with a succession of aerial roots that penetrate the ground.

Fig-birds, perching birds about the size of thrushes, of the genus *Sphecotheres*, peculiar to northern and eastern Australia, New Guinea, the Papuan islands, and Timor. They have usually been placed in the oriole family (Oriolidae), but by some ornithologists are considered to be more nearly related to the cuckoo-shrikes (Campephagidae). Mathews has recently created for them a special family Sphecotheridae.

Yellow-breasted Fig-bird.

The plumage differs in the two sexes, the males being yellowish-green above, with black heads, wings and tails, and yellowish underparts; the females are brown above and whitish below, streaked with brown. In both sexes there is a patch of bare skin round the eye, extending forward to the bill, coloured bright scarlet in males and purplish-grey in females. The common Fig-bird (*S. vieilloti*) is plentiful in the coastal districts from Newcastle to Cairns; the Yellow-breasted Fig-bird (*S. flaviventris*) is found along the northern coast of the continent.

Fig-birds are forest-haunting birds, feeding on scrub fruits, especially those of fig-trees. They associate in small flocks, and when feeding utter loud and curious calls. Their nests are very slight structures of twigs, usually built in the fork of a horizontal branch near its extremity. The eggs vary from light-green to brown, and the reddish-brown markings upon them are also variable.

Finches, perching birds belonging to the families Fringillidae and Ploceidae. The former family is represented in all parts of the world except the Australian region; but since European settlement took place several of its members have become acclimatized in Australia—principally about Melbourne and Sydney, from which centres the majority are gradually spreading northwards and westwards. The House Sparrow (*Passer domesticus*, see NOXIOUS BIRDS) is the only species which has reached Queensland; none have yet succeeded in establishing themselves in Western Australia. In South Australia both the sparrow and the Goldfinch (*Carduelis carduelis*) have become common, and the goldfinch is also acclimatized in Tasmania. In Victoria and New South Wales the Greenfinch (*Chloris chloris*) and Tree Sparrow (*Passer montanus*) are also established.

The indigenous finches of Australia belong to the family Ploceidae, members of which are also found throughout the Malay Archipelago and southern Asia, as well as in Africa, where they are specially numerous. They are usually distinguished as weaver-finches or weaver-birds.

Weaver-finches feed principally on small seeds, especially grass-seeds, their conical, rather stout beaks being adapted for husking grain. Many species occur in very large flocks in those parts of northern Australia where there is a plentiful supply of grass. Their notes consist mainly of chirpings and twitterings; they are not songsters like many of the true finches (Fringillidae). Their nests are bulky, untidy structures of grass, domed, with the entrance at the side, placed in bushes. They lay five or more pure white eggs.

Owing to the bright colours with which they are mostly adorned, and the ease with which they can be captured and kept alive in cages, our finches are favourite birds for aviaries, and thousands are trapped annually in northern Australia for shipment to all parts of the world. Unfortunately a very large proportion die on the journey. Their numbers have become so much reduced from constant trapping in the more accessible districts that the Queensland government has prohibited their capture and export.

Of the 20 species found in Australia and Tasmania, the great majority are confined to the north and north-east of the continent, some of them appearing at times on the inland plains

of the southern States when the grasses are in seed. Four species are peculiar to the southern parts of the continent, all of them brown birds with brilliant scarlet colouring on the base of the tail—whence they are frequently known as fire-tails. The Spotted-sided Finch (*Staganopleura guttata*) and Red-browed Finch (*Aegintha temporalis*) are confined to south-eastern Australia, the Fire-tailed Finch (*Zonaeginthus bellus*) is found in the south-east and in Tasmania, the Red-eared Finch (*Z. oculatus*) is limited to the extreme south of Western Australia.

Of the northern forms, familiar to most Australians as cage-birds, the following are the best-known:—the Chestnut-eared or Zebra Finch (*Taeniopygia castanotis*); the Red-faced or Star Finch (*Bathilda ruficauda*); the Crimson or Blood Finch (*Neochmia phaeton*); the Masked Finch (*Poëphila personata*) and the Gouldian or Painted Finch (*P. gouldiae*). The alternative names in each case are those used by dealers and fanciers. The name 'painted finch' is applied by ornithologists to the rare *Emblema picta* of central Australia.

P. gouldiae is the most strikingly coloured of all our finches. Its head is black, margined with cobalt blue all round; its back green, with a patch of blue on the rump; its breast lilac; and its under-parts golden-yellow, with a patch of white under the tail. It was named by John Gould (q.v.) in memory of his wife. It is also interesting because in some individuals the black on the face becomes replaced by bright scarlet when they are a few years old, in others the black mask is retained throughout life. The scarlet-headed birds were at one time thought to constitute a distinct species. W.B.A.

Finn, Henry (1852-1924), born at Tenterden in Kent on 6 December 1852, in 1871 enlisted in the 9th Lancers and with them served in the Afghan war of 1878-80, gaining the D.C.M. In 1881 he was commissioned 2nd lieutenant in the newly formed 21st Hussars (captain, 1887; major, 1894; lieutenant-colonel, 1900; colonel, 1907; brigadier-general, 1912), and served on the staff of the Madras army as D.A.A.G. (1893-5) and A.A.G. (1895-8). In 1898 his regiment was converted into lancers, and he accompanied it to the Sudan and took part in its famous charge at the battle of Omdurman. In 1900 he left the regiment to become commandant of the military forces in Queensland, in 1902 was transferred to New South Wales, and in 1905 succeeded General Hutton (q.v.) as inspector-general of the military forces of the Commonwealth, with the local rank of major-general. He had worked loyally under Hutton through the difficult reorganization of six State forces into a single Commonwealth force, and carried on the process ably, but was forced for reasons of health to retire from the army in 1907. For a few years he engaged in commerce, but in 1912 was made secretary of the Walter and Eliza Hall trust, and in 1913-17 was private secretary to Sir Gerald Strickland during his governorship of New South Wales. In 1923-4 he was private secretary to the acting-governor, Sir William Cullen. He died after a short illness on 24 June 1924. Both as a man who had risen from the ranks and as a disciplinarian Finn had an excellent influence on the young and inexperienced troops he handled in Australia: he steadily encouraged promotion from the ranks, and at the same time persistently enforced the necessity of taking military training seriously. (C.B., 1907.)

Finniss, Boyle Travers (1807-1893), was born at sea on 18 August 1807, educated at Greenwich and at the royal military college, Sandhurst, and entered the British army in 1825 (ensign, 1825; lieutenant, 1827), but sold his commission in 1835 in order to migrate to New South Wales. However, having been appointed assistant to Colonel Light, the first surveyor-general of South Australia, he accompanied that official to Adelaide in 1836, and during the next 16 years rose steadily through the public service (deputy-surveyor-general, 1839; commissioner of police, 1843; treasurer and registrar-general, 1847) till in August 1852 he became colonial secretary—a position he had already held temporarily during Sturt's absence in 1849. As colonial secretary he carried through the council the first constitution act (which did not receive the royal assent) as well as the final act, and in 1854-5 was acting-governor for about six months. In October 1856 he became first premier of the colony under the responsible-government regime, but resigned in August 1857 after a good deal of friction with Sir R. MacDonnell. In the following June he became treasurer in the Hanson ministry (1858-60), and for the next two years represented Mount Barker in opposition. In 1864 he was appointed first government resident for the Northern Territory, and led an expedition to establish the main settlement at Escape Cliffs on Adam Bay, about 30 miles north of Darwin; but both the choice of site and the conduct of the expedition proved unsatisfactory, and in 1865 Finniss returned to Adelaide, resigned, and retired into private life. In 1875 he was appointed a member of the forest board, resigning in 1881, and devoting himself to the compilation of a *Constitutional History of South Australia*, which was published in 1886. He died on 24 December 1893.

Finniss is often styled 'lieutenant-colonel,' this rank having been conferred on him by an act of the local council in 1854, when for fear of Russian privateers the colony was raising a volunteer defence force of 2000 men. The unsettled state of the world in 1860 caused this force to be revived, and Finniss (who raised a company known as the 'Adelaide Marksmen') was given command of the 1st Adelaide regiment.

First Fleet, The. This article describes the organization, departure, and outward voyage of the first expedition that took convicts to New South Wales—ever since its arrival known as the 'First Fleet'—which was brought into being by a letter from Lord Sydney (then at the home office) to the lords of the treasury, dated 18 August 1786, which set forth the King's pleasure that ships should be provided for carrying '750 convicts to Botany Bay with such provisions, necessaries, and implements for agriculture as may be necessary for use after their arrival.' Upon this instruction were set to work the admiralty, which was responsible for the equipment and officering of the ships, and for the marine guard in the transports; the victualling department, for the provisions; the transport department, for the convict transports; the treasury, for the financial arrange-

ments; and a number of sub-departments. The East India Company also played a part, owing to its monopoly of trade to the East, for three of the transports were under charter to take cargoes of tea from China to London after landing convicts and stores in New South Wales. An enormous amount of correspondence was involved in the preparation which, beginning with the above letter, only ceased on 11 May 1787, when Arthur Phillip (q.v.)—who had been appointed to command the expedition, with the rank of commodore—sent his last despatch on the eve of sailing from Spithead.

In charge of the expedition was H.M.S. *Sirius*, commanded by Phillip in person, with John Hunter as second captain. The *Sirius*, originally named *Berwick*, was built on the Thames in 1781. She was classed as a sixth-rate, and armed with six carronades and four 6-pounders mounted—an armament less than that usually carried in a ship of her size. Ten 6-pounders, with iron-work for building the gun-carriages, were carried in her hold, to be used if required in the settlement. Her burthen was 520 tons, her dimensions about 100 feet by 32 with 12 feet depth of hold: it may assist some readers to conceive her as smaller than the small North Sydney ferry-boats, with a tonnage less than that of the larger Manly ferry steamers. The principle of construction was, of course, entirely different. The tonnage of the whole fleet taken together—3892 tons—was barely half that of the average coastal passenger steamer nowadays plying between Australian ports.

The *Supply*, an armed tender, was the other King's ship, a poor sailer and too small for the work. She was a brig-rigged sloop of 170 tons, commanded by Lieutenant Henry Lidgbird Ball, and carried eight 3-pounder guns and 50 men. The transports were the *Alexander*, Duncan Sinclair master, 452 tons; *Lady Penrhyn*, William C. Sever master, 333 tons; *Charlotte*, Thomas Gilbert master, 335 tons; *Scarborough*, John Marshall master, 430 tons; *Friendship*, (snow), Walton master, 274 tons; *Prince of Wales*, John Mason master, 350 tons. The storeships were the *Fishburn*, R. Brown master, 378 tons; *Golden Grove*, Sharp master, 375 tons; *Borrowdale*, R. Hobson master, 275 tons; making a fleet of two King's ships, six convict transports, and three storeships. The contract with the private ships was at the rate of 10s. per month per ton until their return to Deptford—except in the case of the *Lady Penrhyn*, the *Charlotte*, and the *Scarborough*, which when cleared in New South Wales ended their contract and began a new one with the East India Company. The other three transports and three storeships were to return to England in charge of Lieutenant J. Shortland (q.v.), agent for the transport department. The contracts for the most part were carried out through William Richards, a shipbroker of Walworth. The owners and masters of the vessels were supplied with warrants to 'secure and keep in safe custody' the prisoners, and entered into bonds to do so. Richards also contracted to supply the provisions, which were to be at the rate of two-thirds the allowance to seamen in the navy, and Zachariah Clarke was sent out in one of the ships to see to the contractor's interests. The transports were fitted for convicts as they would have been for troops, with hammocks, mess tables, and stools; but thick bulk-heads three feet high, studded with nails, were run across between decks from side to side abaft the mainmast, with loopholes to fire through in case of mutiny. This also prevented communication between the ship's company and the convicts and their guard. The hatches were secured with cross-bars, bolts and locks, and railed round from deck to deck with oak stanchions. Sentries were stationed at each, and a guard, always under arms, was kept on the quarter-deck to prevent any sudden outbreak. It was fortunate that nothing of this kind occurred; for among the few things forgotten by the authorities was ammunition for the guard, whose only supply was obtained from the small arms magazine on board the *Sirius*.

The food and water supply for the long voyage was a serious problem. It concerned about 1480 persons, most of whom were totally unaccustomed to sea life, unhealthy in every sense of the word, and highly receptive of such diseases as scurvy and the disorders that arise from close confinement and poor living. The voyage, moreover, was to end with their arrival in a country remote from help, affording neither food nor shelter, inhabited, for all they knew to the contrary, by a savage race and infested by wild beasts. The supply of food and water was, fortunately, plentiful, good and (incredible as it may seem) both in quality and quantity superior to that often served to merchant seamen in British sailing-ships down to very recent times. The official ration of water was three quarts per day per man; the food scale two-thirds, as already mentioned, of that fixed for the naval service—which was, per week per man, bread (i.e. biscuit) 7 lb., salt pork 2 lb., salt beef 4 lb., peas 2 lb., oatmeal 3 lb., butter 6 lb., cheese ¾ lb., vinegar ½ pint. The scale was not adhered to, the whole ration being largely increased, and varied by rice, portable soup, and dried fish. When in port, and as long after as the stock of fresh provisions lasted, fresh meat and vegetables in plenty were supplied. The ration was increased up to 20 oz. of meat and 1 lb. of rice per day in ports where these foods were cheap. The women and children were given a special diet, and the sick allowed wine and spirits. The prisoners were supplied with hammocks and blankets, and clothing for the year, consisting of two jackets, four pairs of woollen drawers, one hat, three pairs of worsted socks, three frocks, three pairs of trousers, and three pairs of shoes; and the women with suitable apparel. During the voyage the water ration sometimes had to be reduced; but not for long, as the supply was nearly always sufficient to last between ports and was, of course, renewed whenever rain fell. Some notion of the quantity of food necessary to be carried, not only for the voyage but to supply the settlement after landing, can be gained from documents showing the state of the stores at Sydney in September 1788, on which 933 persons were to be victualled:—flour 414,176 lb., 52 weeks' rations; rice 51,330 lb., 15 weeks' rations; beef 127,608 lb., 43 weeks' rations; pork 214,344 lb., 128 weeks' rations; peas 2305 lb., 58 weeks' rations; butter 15,450 lb., 49 weeks' rations.

The ships' decks were crowded with pens containing sheep, hogs, goats, puppies, kids, turkeys, geese, ducks, chickens, pigeons, and cats. More live stock, as well as seeds, were taken on board at the Cape of Good Hope—one bull, one bull-calf, seven cows, one stallion, three mares and three colts, 44 sheep, four goats,

28 boars and breeding sows; and the officers bought such private stock as room could be found for in the different ships. The following plants and seeds were procured:—at Rio de Janeiro coffee (seed and plants), cocoa beans in the nut, cotton-seed, bananas, oranges, lemons, tamarinds, guava-seed, prickly pear (plants, with the cochineal on them), 'eugenia or pomme rose,' jalap, and three sorts of ipecacuanha; at the Cape fig-trees, bamboos, sugar-cane, 'Spanish reed' (possibly esparto grass), vines, quinces, apples, pears, strawberries, oaks, and myrtles, besides rice, wheat, barley, maize, and other grains. Both at Rio and at the Cape Phillip bought sheep on government account, but the cost and bulk of their fodder made it impossible to bring along many. The officers, realizing that for some years their future abode would be almost completely cut off from civilization, brought with them much furniture and clothes and some luxuries: the surgeon of the *Sirius*, for instance, brought out a piano, which he left with the Macarthurs when he returned to England in 1791.

Naval and marine officers, naval surgeons, and four civilians constituted the governor's staff. As most of them are referred to under other headings, and many under their proper names, it is only necessary here to give a list of the establishment: governor-in-chief, Arthur Phillip; lieutenant-governor, Robert Ross (also major commanding marines); chaplain, Richard Johnson; judge-advocate, David Collins (a captain of marines); surveyor-general, Augustus Alt; commissary of stores, Andrew Miller; assistant commissary, Zachariah Clarke; provost-marshal, Henry Brewer (Brewer was a midshipman in the *Sirius* and was appointed on the voyage out, as George Alexander, who had been given the position, resigned at the last minute before sailing); peace officer and bailiff of the government, James Smith. Lieutenant George Johnston of the marines acted as aide-de-camp to the governor, and Lieutenant William Dawes of the marines as engineer and artillery officer. The hospital establishment was—surgeon-general, John White; first assistant, Dennis Considen; second assistant, Thomas Arndell; third assistant, William Balmain. The naval establishment was—H.M.S. *Sirius*: Captain, Arthur Phillip; second captain, John Hunter; lieutenants, William Bradley, Philip Gidley King, and George William Maxwell. H.M.S. *Supply*: Lieutenant Henry Lidgbird Ball, commander. There were also surgeons Bowes and Alltrees in the transports; surgeon G. B. Worgan and surgeon's mate Thomas Jamison in the *Sirius*; and surgeon Callan in the *Supply*. For the voyage all surgeons were under the surgeon-general. There were four companies of marines, which included one major, two captains, two captain-lieutenants, nine first lieutenants, four second lieutenants, one adjutant, one quartermaster, one judge-advocate, 12 sergeants, 12 corporals, eight drummers, and 160 privates. The captains were:—James Campbell, John Shea, David Collins (judge-advocate); captain-lieutenants (a rank since abolished) James Meredith, Watkin Tench; first lieutenants, James Maxwell, John Creswell, John Poulden, James M. Shairp, John Johnston, George Johnston (aide-de-camp), Robert Kellow, Thomas Davey, Thomas Timins, and James Furzer, quartermaster. The second lieutenants were William Dawes (engineer and artillery officer), Ralph Clarke, William Faddy, William Collins (brother of the judge-advocate), and John Long, adjutant. John Ross, son of the major, was a volunteer without pay, and there were 28 wives and 17 children belonging to the men of the detachment. The crew of the *Sirius* numbered 160 men; of the *Supply* 50 and the transports and storeships had crews varying from 30 in the largest to 22 in the smallest, with a total of 233.

Lieutenant Watt, R.N., was a passenger by the *Lady Penrhyn* on his way to China. Many of the junior officers of the *Sirius* and *Supply* afterwards came into prominence in the work of the settlement. The purser, John Palmer, became commissary; Henry Waterhouse, Newton Fowell, and Daniel Southwell, mates and midshipman, won their promotion on the station. Merton, master of the *Sirius*, and two midshipmen were invalided home from Rio de Janeiro. James Keltie, who had served as a master in the navy, but was acting as mate of the *Fishburn*, was appointed master in the *Sirius*, and in that capacity had much to do with the survey of Sydney Harbour. A midshipman, Francis Hall, disappeared—lost, it was supposed, in the bush on the shores of Port Jackson—in November 1789, and was never afterwards heard of. Ross, the gunner of the *Sirius*, died on his way home. Donovan, midshipman, and Brooks, boatswain, were largely employed in boat work at Norfolk Island, and became expert pilots for its dangerous coast. The three Shortlands in the fleet are referred to under their names. David Blackburn, master, and Robinson Reid, carpenter, of the *Supply*, were highly commended for their work by Phillip.

Authorities disagree curiously concerning the number of prisoners. Collins gives 756, Tench 757, Phillip's *Voyage*, 778, Hunter's *Voyage* 800; and each of these accounts varies the number in different parts of the same book. A transportation office return, dated 13 June 1794, gives the number as 778; this agrees with a return of the house of commons select committee on finance, dated 26 July 1798, and approximates to the figures given in the appendix to Phillip's *Voyage*, which supplies a list of names, places of conviction and sentences, making a total of 780, and to a return sent from Santa Cruz by Phillip, dated 10 June 1787. The latter document is probably the best authority, as it was made out when the fleet had been long enough at sea to have the accounts in order. The return is as follows:—marines, including officers, 197; marines' wives, 28; marines' children, 17; chaplain and wife, 2; surveyor-general, 1; surgeon and assistants, 5; servants, 2; men convicts, 558; women convicts, 192; children, 13; convicts dead since embarking, 21; convicts' children dead since embarking, 3; received King's pardon before the fleet left, 2. This gives a total of 789 convicts and their children embarked, of whom 2 were pardoned; the fleet therefore sailed with 771 prisoners and 16 children of convicts. Add to this 252 guards and officials, 210 seamen of the navy, and 233 merchant seamen, and we reach a grand total in the fleet of 1482 persons.

The *Charlotte* and *Friendship*, transports, took on board their prisoners at Plymouth, the other ships at Deptford and Spithead, where the whole fleet was ordered to rendezvous. The ships assembled on 17 March 1787. H.M.S. *Hyaena* under Captain Michael de Courcy joined the squadron on 12 May to escort it to sea. Some insubordinate seamen on the transports were removed to the *Hyaena*, and volunteers from

her took their places. Little notice was taken of the ships as they lay in sight of Portsmouth and the Isle of Wight, fleets of 200 or 300 sail being then by no means uncommon when the West India convoy was waiting for a fair wind down channel. Newspapers were not numerous, and were full of the trial of Warren Hastings, or the morganatic marriage of the Prince of Wales and Mrs. Fitzherbert. Two or three lines, to the effect that the fleet destined for Botany Bay had departed, is all the mention made of it in the press. But two private references to the sailing are still extant. The minister of a church in the Isle of Wight recorded in his diary that, as the convoy left Spithead, he prayed for its safety and for the souls of the prisoners. And an anonymous officer, writing in the *United Services Journal* for December 1846, described the embarkation of convicts at Portsmouth:

> I recollect perfectly all the shop-windows and doors of Portsmouth being closed on this occasion, and the streets lined with troops while the waggons—I think 30 in number—passed to Point Beach, where the boats were ready to receive them. As soon as they were embarked, they gave three tremendous cheers, and were rowed off to the transport ready for their reception at Spithead.

At daybreak on the morning of 13 May the fleet passed through the Needles. The ships were three days clearing the channel, and on 20 May hove to about 200 miles west of Scilly and sent letters and despatches by the *Hyaena*. On 3 June the fleet arrived off Teneriffe, anchoring in Santa Cruz roads, about a mile from the town. By this time warm weather and tropical rains necessitated strict enforcement of health regulations. The passengers were not allowed to get wet; explosions of gunpowder between decks, and a liberal use of oil of tar and lime, sweetened the ships. The problem of ventilation was doubly difficult in the female convict transports, as it was found absolutely necessary to keep the women locked up below at night to prevent intercourse with the guard and the seamen. Although windsails were rigged, the heat below was so great that women were continually fainting. On 6 July it became necessary to put everyone, without exception, on three pints of water per day, exclusive of cooking, for which one quart per man was allowed; this shortage of water soon brought on symptoms of illness, although the diet had been improved by catching a great number of fish. The equator was crossed on the evening of 14 July, but no ceremony of any kind was observed. So far the fleet had had moderate to fine weather; but on 23 July the wind increased, and during the ensuing three days some of the ships lost a few light spars in heavy squalls. On 4 August the fleet anchored in the harbour of Rio de Janeiro, and on the following day, at the invitation of the viceroy, came farther up the bay and anchored a mile and a half from the landing-place. Don Luiz de Varconcellos, viceroy of the Brazils, received Phillip and his officers with great kindness, remembering that Phillip, who spoke Portuguese well, had served with distinction in the navy of his sovereign. During the month the ships spent in port they were supplied at reasonable charges with everything needed. On 4 September the fleet got under way again, and on 13 October, at seven in the evening, reached Table Bay and anchored a mile and a half from the shore. The Dutch governor, Mynheer van Graaf was polite but unhelpful, explaining that the colony was short of provisions, and was not in a position to sell all that would be required, except at high prices. However, negotiations resulted in Phillip's obtaining sufficient to serve out 1½ lb. of fresh meat and a like quantity of soft bread per day to everyone in the fleet during its stay. Live stock was also obtained. On 13 November the ships were under way again. On 25 November Phillip, taking with him P. G. King and Dawes, changed his pennant to the *Supply*, and with the three best sailers in the fleet (the *Alexander*, *Scarborough*, and *Friendship*) went on ahead to make preparations for the landing, leaving Hunter in charge of the other ships. The two squadrons lost sight of each other the following evening. At early morning on 7 January 1788 the *Lady Penrhyn* signalled land in sight, and at 4 p.m. that day they sighted the Mewstone, near the South Cape of Tasmania—at that time believed to be the southernmost point of the Australian continent. Hunter did not make the land until he sighted Red Point (so called by Cook—really one of the Five Islands near Wollongong) on 19 January. Next day they entered Botany Bay, and were at anchor at 8 a.m. The *Supply* was only 40 hours ahead of them, and the three transports that had been detached with her only 20.

The voyage had taken eight months and one day, and the distance sailed was 15,063 miles. The ships had not, except by design, lost sight of each other for an hour, although nine of them were small merchantmen, and the greater part of the sailing was in unknown waters. Add to this that the death-rate was very low, although the ships were crowded to an extent incredible in the present day, and the people on board belonged to the most difficult and unhealthy class of passengers, many of them having left England in a very sickly state—and the success of this remarkable voyage can be appreciated. The officers of the fleet attributed much of the success of the voyage to the good quality of the provisions.

See Collins's *Account of New South Wales* (London, 1798); Phillip's *Voyage* (London, 1790); Hunter's *Historical Journal* (London, 1793); Tench's *Narrative of the Expedition to Botany Bay* (London, 1789); White's *Journal of a Voyage to New South Wales* (London, 1790); Gilbert's *Voyage from New South Wales to Canton* (London, 1789); *The Historical Records of New South Wales*; Bradley's journal and other mss. and pamphlets in the Mitchell Library, Sydney; contemporary newspapers and periodicals; and the log-books of some of the transports.

W.J.

Fisher, ANDREW, born at Crosshouse in Ayrshire, Scotland, on 29 August 1862, worked in the local collieries from the time he was 10 years of age until in 1885 he migrated to Queensland. There for eight years he worked on the Burrum coal-field and at the Gympie diggings. At Gympie he made himself a prominent member of the then just-born Labour party, and in 1893 was elected for that constituency to the Queensland assembly; he lost the seat in 1896, but regained it in 1899, and became minister of public works in the extremely short-lived cabinet of Anderson Dawson (q.v.). Wide Bay returned him to the first federal house of representatives in 1901, and continued to do so until he left politics altogether in 1915. Making his name as a slow-moving but upright and hard-headed politician, he was taken

into Watson's first Labour ministry as minister for trade and customs, became deputy-leader of the party when it went into opposition, and when Watson was forced by ill-health to resign in 1907 succeeded him as leader. For a time he supported the Deakin ministry, but in November 1908 withdrew his support, drove Deakin from office, and himself became prime minister and treasurer. Defeated in the house in June 1909 by a parliamentary combination of Deakin's and Cook's followers, he was returned at the head of a good majority at the elections of 1910, formed his second ministry, and was responsible within the next three years for the transfer of the Northern Territory to the Commonwealth; the establishment of the Commonwealth Bank (q.v.) and the issue of bank-notes by the federal treasury, superseding all private bank issues; the imposition of a federal land tax, the construction of the transcontinental railway (east-west) and the creation of the inter-State commission. He was also largely responsible for the creation of the Australian squadron (which he initiated during his 1908-9 term with the building of destroyers), and the development of the compulsory training military system; but these matters were on the whole outside party politics, and the Deakin ministry of 1909-10 and that of Cook in 1913-4 had also an important share in the complete organization of Australian defence, the first in particular being responsible for accepting the 'unit' scheme for the squadron and Lord Kitchener's advice about the citizen forces. In 1913 Fisher was defeated by a very small majority at the June elections, but those of September 1914 restored him to power just after the Great War had begun, and the despatch of the first contingents (which had been offered by his predecessors) and the maintenance of the Australian effort up to October 1915 were effected under his control. In that month he resigned his post, and his seat in parliament, to become high commissioner, and held that position until 1921, when ill-health forced him to retire altogether from public life.

While prime minister the second time, he attended the Imperial conference (q.v.) of 1911—the first at which Dominion ministers were taken into the confidence of the Imperial government about matters of foreign policy—and was made a privy councillor. The knowledge of world affairs he then acquired made him more than ever a steadying influence among the less experienced and more excitable members of his party, and an important factor in securing Australian unanimity when the strain of the war was first felt.

Fisher, Sir James Hurtle (1790-1875), son of a London architect, was born in 1790 in London, articled to a firm of solicitors in 1804, and in 1811 commenced practice in Cavendish Square, London. In 1835 he was selected by the South Australian commissioners to fill the office of land-commissioner in Adelaide, which he reached with Captain Hindmarsh on 28 December 1836. Almost at once he found himself at odds with the governor over the location of the first township, the naming of places and the disposal of land. Fisher contended that these matters were entrusted to him, the governor considered himself supreme; neither would give way, and the deadlock lasted 14 months. In July 1838, however, Hindmarsh was recalled; his successor, Colonel Gawler, was appointed to the joint position of governor and resident commissioner; and Fisher, his commission withdrawn, reverted to legal practice as a private citizen. In October 1840 he was elected first mayor of Adelaide. In 1849 he advocated responsible government, and in 1853 was elected a member of the old mixed council; defeated in 1855, he became a nominated member, and was speaker of the council that legislated for responsible government. He was returned to the first council under the new constitution, and in April 1857 elected its first president, a position he held until he left public life in February 1865. For some time after this he was leader of the South Australian bar. He died at Adelaide on 28 January 1875. (Kt. Bach., 1860.)

Fisheries. See Angling and Trawling.

Fisher's Ghost. The story of this alleged ghost, described as 'well authenticated' and 'testified to by people still alive,' for over 70 years went the rounds of English and Australian periodical literature. The ascertained facts are therefore worth recording.

In 1826 two ticket-of-leave men, Frederick Fisher and George Worrall, were living together on Fisher's farm near Campbelltown in New South Wales. On the evening of 17 June Fisher left a hotel at Campbelltown in company with some friends, and not long afterwards one or two of them returned to the hotel saying that they thought Fisher had done so before them. He was not there, and was never seen again alive. Worrall, when questioned some days later, said that his friend had left the colony hurriedly in order to avoid a prosecution for forgery, leaving him authority to deal with the property; he accordingly sold some of the stock, and offered to pay a debt left by Fisher if the deeds of the farm were handed over to him. Although the affair was highly suspicious, no action was taken on it for four months, by which time the authorities seem to have satisfied themselves that Fisher had certainly not left the colony and that an investigation was due. About that time, the story goes, a man named Farley reported with every sign of terror that he had seen Fisher's ghost sitting on the sliprails of a paddock and pointing to the paddock. But of his supposed report there is no contemporary evidence; that only shows that, a reward having been offered, a constable began his investigations where blood-marks had been noticed on a fence, and with the help of two aboriginals followed certain signs to a marshy spot in Fisher's paddock where the body was found. Worrall was arrested, tried, and convicted of the murder, and before his execution admitted that he had killed Fisher, but told a provably false story of the killing.

The advertisement offering a reward for evidence of Fisher's death or departure from the colony appeared in the Sydney press at the end of September 1826. On 3 November the *Monitor* published an account of the discovery of his body 'with the help of three blacks, in a field three feet below the surface of the ground,' and within a week the authorities were advertising for 'James Smith, alias Froggy' as an accomplice in the murder. There is no hint of supernatural guidance either in the *Monitor's* story or in the fuller accounts of the tragedy which are given (in connection with Worrall's trial and conviction) in the *Sydney Gazette* of 5 February 1827 and in contemporary issues of

the *Monitor* and *Australian*. The story of the ghost was mentioned briefly in R. M. Martin's *History of the British Colonies* (vol. iv., pp. 303-4), published in London in 1835; a very full account occurs in *Tegg's Monthly Magazine* for March 1836, and from this all later versions were derived. According to W. H. Suttor (*Australian Stories Retold*, 1887) the superintendent of police at Campbelltown admitted to a friend that Farley had made the report, and that his story set the actual search going; but this is later and third-hand evidence. It is noteworthy (*a*) that no mention is made of the story at the trial; (*b*) that the ghost was not seen until, after a lapse of four months, the authorities were commencing their investigations; (*c*) that neither Farley nor any of Fisher's companions at the hotel were called to give evidence. The narrative is complete and self-sufficing without Farley. If, however, we assume that Farley did make such a report, the probabilities are that it was his way of securing himself at the same time from arrest as an accomplice and from public contempt as an informer. Suttor's discussion of the story should be studied by all serious inquirers. W.J.

Fishes of Australia. Approximately 1800 species of fishes are at present known to occur in Australian and Tasmanian waters; of these the greater number have been found on the eastern coast-line. No doubt many more await discovery in southern, western, and northern waters. The deep seas of the Australian region remain almost unexplored; but such investigations as have been carried out with dredge and trawl indicate the presence of a rich and interesting fish-fauna. From the reefs surrounding the isolated Lord Howe Island (q.v.) Waite has recorded nearly 200 species, many tropical, others from the Australian coast; the known fish-fauna of Norfolk Island is small, and closely resembles that of Lord Howe Island. The tropical coast-line, coral reefs, and numerous rivers of Papua support an exceedingly large number and variety of species, of which comparatively few have as yet been recorded; and the literature relating to them is so scattered that no estimate of their number can be made.

The marine fish fauna of Australia is composed of three elements—species derived from the north, southern forms, and deep-sea types. The tropical forms that have wandered southward along our coasts are the most numerous, and commonly extend as far down as 30° S., lat.; some have straggled even farther south. The southern types form a very distinct group, ranging over the whole coast-line south of 30° S., and extending to New Zealand. A few—e.g. the warehou (*Serio'ella*), barracouta (*Thyrsites*) and rockling (*Genypterus*)—are circumpolar, but the majority are restricted to the waters of southern Australia, Tasmania, and New Zealand. As for our deep-sea fishes, specimens taken by the *Challenger* and more recently by the federal investigation vessel *Endeavour* bear a marked resemblance to those described from the deep waters of Japan, Hawaii, and the Indian Ocean, while some are identical with species occurring in the Mediterranean, and the neighbouring Atlantic Ocean.

The freshwater fishes of Australia and Papua are almost all closely related to marine genera, and have evidently migrated from the sea since the early Eocene period, after this region had been severed from Asia by water barriers. The great sub-order Ostariophysi, which includes all the carps and catfishes so characteristic of the fresh waters of other parts of the world, is represented in Australia by a few catfishes of the marine families Plotosidae and Ariidae. Several introduced species of carp, including the gold-fish (*Carassius auratus*), have become exceedingly plentiful over a large area; they are, however, of little value as food and, as they destroy the eggs of other more valuable species, are to be regarded as pests. The only indigenous freshwater types are the archaic Burnett River salmon (*Epiceratodus*) and burramundi (*Scleropages*) of Queensland rivers, which are survivors of an ancient fauna. The Murray cod (*Oligorus*), the perch (*Percalates*) and the grunters (*Therapon*), are all members of the family Serranidae, so largely represented in all seas. Certain species of mullets (Mugilidae), silversides (Atherinidae) and gudgeons (Gobiidae) have been likewise recruited from the sea, and some are capable of living in either fresh or salt water. The jollytails (*Galaxias*) spend most of their lives in fresh water, but some species go through their larval stage in the sea.

The remarkably uniform climatic conditions of the greater portion of the Australian continent, combined with the intercalating river systems, have enabled the fishes inhabiting them to extend their range over very wide areas. As the watersheds between many of the rivers are very low, fish are able to pass from one to another in times of flood; and extraordinary aid to their distribution is afforded by whirlwinds, which occasionally sweep small fish out of a pool, transport them a short distance, and drop them in some neighbouring creek that they would otherwise have failed to reach. Such whirlwinds are common in the central areas, and have doubtless served to extend the range of both freshwater fishes and crustaceans. For an account of falls of fish during thunderstorms see Ogilby in the *Proceedings* of the Royal Society of Queensland, vol. xx. (1907), p. 29. The Spangled Grunter (*Therapon unicolor*) ranges from the western rivers of New South Wales and Queensland through central Australia to the north-western part of the continent; it has even been known to make its appearance in artesian waters soon after they have begun to flow from the bore-head, and has been erroneously supposed to have come up with the bore-water. Some specimens living in such conditions are blind, their eyes being more or less decayed, possibly from the action of gases contained in the water (Coleridge in *Report* for 1912 of the Australasian Association for the Advancement of Science, p. 354).

In common with many other aquatic animals, Australian freshwater fishes have a remarkable capacity for aestivating during long periods of drought. As a stream or pool dries up, the fish in it bury themselves in the mud, and there remain in a dried state until further rains release them. By this means areas which were previously dry are speedily stocked with fish when a flow of rain-water or artesian bore-water provides suitable conditions.

The freshwater fishes of Papua are very similar to those of Australia, and include a number of species of *Therapon* and *Atherines* of the sub-family Melanotaeniinae. As in all tropical places, a large number of marine fish penetrate the rivers far beyond reach of the tide.

Literature.—Most of the early British and French voyagers to Australia were accompanied by naturalists, who made more or less extensive collections of our fishes. Some of those taken during Cook's voyage were described in the 1780s, and a small number of species from Port Jackson and its vicinity were described and figured by Shaw in 1790, in White's *Voyage to New South Wales.* The French collector Péron sent to the Muséum d'Histoire Naturelle Australian fishes which were later described by Cuvier and his collaborator Valenciennes; many others were collected and described by Quoy and Gaimard in the 1820s. Sir John Richardson's report on the fishes taken during the voyage of the *Erebus* and *Terror* did much to advance knowledge, and many of his descriptions are even now the best published. In 1843 he published what is apparently the first catalogue of authentically Australian fishes. During the next 40 years the subject was handled by Günther, Steindachner, Castelnau, Macleay, Klunzinger, and others; Dr. Günther's *Catalogue,* published by the British museum (8 vols., 1859-1870), supplied brief descriptions of most of the species then known from Australia, and served as a basis for all subsequent workers. During the seventies Castelnau dealt principally with the fishes of Victoria, but the value of his work was greatly discounted by inaccuracy. A bibliography of Australian ichthyological literature published by Klunzinger in 1879 is all-important to Australian students; his own papers, illustrated by Konopicky, were of a high standard.

Collections from the Northern Territory were examined by Sir William Macleay, who collected extensively on the coasts of Queensland and New Guinea in the *Chevert* expedition. He also reported upon specimens collected by Masters in King George's Sound, and formed what was then the largest collection of Australian fishes; this is now preserved at the university of Sydney. His *Catalogue,* though sadly out of date, is still the only work which deals with our fishes as a whole. Largely a compilation from Günther, with scattered descriptions of other writers sorted into their places, it also included the results of much original research.

Professor McCoy described, and figured in colour, numerous Victorian fishes in his *Prodromus of the Zoology of Victoria* (2 vols., 1878-1890). J. E. Tenison Woods in 1883 was the first to combine descriptions and illustrations of the fishes of New South Wales with notes on their habits and the methods employed in their capture. Important publications dealing with edible fishes of New South Wales have been published by Ogilby and Stead. Valuable lists have been prepared by R. M. Johnston (of Tasmanian species), A. H. S. Lucas (Victorian), Ogilby & Waite (New South Wales), Zeitz (South Australian), and Woodward (Western Australian). Catalogues of the fishes of Lord Howe Island and Norfolk Island have been published by Waite. Publications of scientific societies and museums in the several States include many smaller contributions. An illustrated work entitled *Fishes of Australia* by D. G. Stead (1906) provides a general account of New South Wales species; a later work, with the same title, by T. C. Roughley (1916) includes a general account of the fishes and fishing in New South Wales, together with a number of coloured plates of local species; and the writer of this article has published (1922) a fully illustrated list of all species found in New South Wales waters.

The following list, which includes the most usual vernacular names of the principal Australian fishes, shows their inter-relationship and their place in the general ichthyological scheme.

Class Elasmobranchii, sub-class Plagiostomi:

- Order Selachii—Sharks, including Seven-gilled Shark, Port Jackson Shark or Bullhead, Tiger Shark, Hammer-headed Shark, Wobbegong or Carpet Shark, Thresher Shark, Grey and Blue Nurse, Blue Pointer, White Shark, Basking Shark, Dog-fish, Saw Shark, Angel Shark or Monkfish, Tope.
- Order Batoidei—Rays, including Sawfish, Shovel-nosed Ray, Fiddler, Electric Ray or Numbfish, Skate, Sting-ray or Stingaree, Eagle Ray, Devil-fish or Diamond-fish, Thorn-backed Ray.

Class Elasmobranchii, sub-class Holocephali:

- Order Holocephali—Elephant-fish, Ghost Shark.

Class Pisces, sub-class Teleostei:

- Order Isospondyli—Herring, Anchovy, Sprat, Pilchard, Bony Bream, Jollytail, Trout, Grayling, Smelt, Yarra Herring, Barramundi.
- Order Iniomi—Sergeant Baker.
- Order Ostariophysi—Catfish.
- Order Apodes—Eel.
- Order Solenichthyes—Pipefish, Seahorse.
- Order Synentognathi—Long Tom, Flying-fish, Garfish or Halfbeak.
- Order Anacanthini—Beardie, Red Cod.
- Order Berycomorphi—Nannygai, Roughy, Dory.
- Order Allotriognathi—Ribbon-fish.
- Order Heterosomata—Flounder, Sole.
- Order Percomorphi—
  - Families:
    - Mugilidae—Grey Mullet, Tallegalane.
    - Sphyraenidae—Sea Pike, Threadfin.
    - Stromateidae—Trevalla.
    - Serranidae—Red Perch, Orange Perch, Rock Cod, Queensland Groper, Wirrah, Banded Sea Perch, Murray Cod, Freshwater Perch, Golden Perch, Macquarie Perch, Spangled Grunter, Silver Perch, Trumpeter, Giant Perch.
    - Sillaginidae—Whiting.
    - Pomatomidae—Tailor.
    - Carangidae—Yellow-tail, Trevally, Pennant-fish, Pilot-fish, Kingfish, Samson-fish, Dart.
    - Centropomidae—Pearl Perch.
    - Arripididae—Australian Salmon.
    - Lutianidae—Sea Perch, King Snapper, Hussar.
    - Nemipteridae—Butterfly Bream.
    - Pomadasidae—Javelin-fish, Sweetlips.
    - Gerridae—Silverbelly.
    - Sciaenidae—Jewfish, Teraglin.
    - Mullidae—Red Mullet or Goatfish.
    - Lethrinidae—Island Snapper or Emperor Bream.
    - Sparidae—Snapper, Black Bream, Tarwhine.
    - Kyphosidae—Silver Drummer.
    - Girellidae—Blackfish, Bluefish, Black Drummer.
    - Monodactylidae—Silver Batfish.
    - Scorpididae—Mado, Sweep.
    - Scatophagidae—Butterfish.
    - Platacidae—Batfish.

1. White Trevally (*Caranx georgianus*).
   Dart (*Trachinotus botla*).
   Young Snapper, or Red Bream (*Pagrosomus auratus*).
2. Snapper (*P. auratus*).
   Bluefish (*Girella cyanea*).
6. Giant Boarfish (*Paristiopterus labiosus*).
7. Red Gurnard (*Chelidonichthys kumu*).
8. Sharp-beaked Gurnard (*Pterygotrigla polyommata*).
9. Dusky Flathead (*Platycephalus fuscus*).
10. Yellow Leather-jacket (*Cantherines ayraudi*).

Chaetodontidae—Coral-fish.
Enoplosidae—Old Wife.
Cheilodactylidae—Sea-carp, Jackass-fish, Morwong.
Pomacentridae—Demoiselle, White-ear.
Labridae—Wrasse or Parrot-fish, Maori, Blue Groper, Pig-fish.
Neoödacidae—Rock Whiting, Herring Cale, Rainbow-fish.
Gadopsidae—River Blackfish.
Scombridae—Mackerel, Bonito, Tunny, Albacore.
Xiphidae—Spear-fish.
Istiophoridae—Sail-fish, Sword-fish.
Trichiuridae—Hair-tail, Frost-fish.
Gempyllidae—Barracouta.
Siganidae—Black Trevally.
Gobiidae—Goby, Gudgeon, Mud-skipper.
Blenniidae—Blenny, Weed-fish.
Order Discocephali—Sucker-fish.
Order Scleroparci—Red Rock Cod, Gurnet Perch, Bullrout, Fortesque, Gurnard, Flathead.
Order Pediculati—Angler.
Order Plectognathi—Trigger-fish, Leather-jacket, Box-fish, Cow-fish, Toado, Porcupine-fish, Sun-fish.

A.R.McC.

Fison, Lorimer (1832-1907), born at Barningham in Suffolk on 9 November 1832, and educated at Sheffield and at Caius College, Cambridge, in 1856 migrated to the Victorian goldfields, and in 1861 entered the university of Melbourne. While there he joined the Wesleyan ministry, was ordained in 1863, and was at once sent to do mission work in Fiji. Returning to Australia in 1871, he happened to meet A. W. Howitt, who had for some years past interested himself in anthropological studies among the Australian natives; the two at once entered on a remarkable personal friendship and scientific collaboration, which resulted in the publication at Melbourne in 1880 of *Kamilaroi and Kurnai,* which Sir J. G. Frazer described as 'a document of primary importance in the archives of anthropology.' Long before this, however, Fison had returned to Fiji—Britain had annexed the group in 1874, and his knowledge of the natives was much needed by the new government. He was an invaluable friend to Sir W. MacGregor and Sir J. B. Thurston, as well as to officials, merchants, and planters. His *Land Tenure in Fiji* (1881), first published in the *Journal* of the Anthropological Institute, was reprinted in a British Blue Book, republished in 1903 by the Fiji government press, and translated into German.

In 1884 Fison left Fiji for Victoria, residing first at Hawthorn, then at Flemington, finally at Essendon (all suburbs of Melbourne). From 1888 to 1905 he edited the *Spectator,* a local Wesleyan periodical; he also helped to found Queen's College within the university of Melbourne, and was one of its first fellows. In 1892 he was president of the anthropological section at the Hobart meeting of the Australasian Association for the Advancement of Science, and on the invitation of the British Association visited England in 1894 to represent Australia at the association's meeting at Oxford, where he was associated with Professor Tylor and Max Müller. In 1904 he published *Tales from Old Fiji.* In 1905 A. J. Balfour, then British prime minister, allotted him a civil list pension of £150 for his distinguished services to anthropology. He died at Essendon on 29 December 1907.

Fitzgerald, Charles (1798-1887), born in 1798, entered the royal navy in 1809, served in a naval campaign against Algiers, was made commander in 1840 and retired in 1856 with the rank of captain. From 1844 to 1847 he was governor of Gambia in West Africa, and was thence transferred to Western Australia, entering office there on 12 August 1848. His term of office included several notable events in the colony's history. In 1848 the first systematic census was taken; on 1 June 1850 the first convicts arrived (reformatory boys had been coming since 1843); the next year (on 13 March 1851) the colony was offered a representative legislative council, but did not take advantage of the offer (see Constitutions); in 1853 a chamber of commerce was founded, and in 1854 the first postage stamps were issued. Almost at the outset of his governorship Fitzgerald nearly lost his life, being speared in the leg by hostile blacks while returning from a visit to mineral lands just discovered by A. C. Gregory (q.v.) in the basin of the Murchison. He resigned his position in July 1855, and returned to England, where he died on 29 December 1887. (C.B., 1857.)

Fitzgerald, John Foster Vesey—known in Australia by his earlier name John Fitzgerald Leslie Foster—son of the Irish judge John Leslie Foster, was born in Dublin on 19 August 1818 and educated at Trinity College, Dublin (B.A., 1839). In 1841 he migrated to Port Phillip to take up pastoral pursuits, and from 1846 to 1848 represented the district in the New South Wales council. In July 1848 he was nominated for Melbourne, but was rejected in favour of Earl Grey (see Victoria); he was, however, in 1849 re-elected for the district of Port Phillip, but held the seat for one year only. After a visit to England he returned to the colony as colonial secretary, succeeding Lonsdale; in this capacity he administered the government in the interval between Latrobe and Hotham, passed the act that gave Victoria responsible government, turned the first sod of the Williamstown railway, introduced the telegraphic system, and took an important part in the conflict between miners and government that culminated in the Eureka Stockade. Although he was by no means responsible for many of the actions that embittered the miners' feeling, he was selected as scapegoat when they forced the governor's hand, and in December 1854 resigned in order to restore public confidence in the administration—a patriotic act which was its own reward. In 1856 Williamstown returned him to the new assembly, but among the newcomers he was out of his element; for seven weeks he was treasurer in the O'Shanassy ministry of 1857, and then retired to England, where he lived the rest of his life. From 1860 onwards, his mother having altered her name and that of her issue in accordance with the will of her brother the last Lord Fitzgerald, he was known by the name under which he appears here. He was still alive in 1892, but his death seems to have occurred soon afterwards.

FitzRoy, Sir Charles Augustus (1796-1858), grandson of that duke of Grafton who helped to lose Britain her American colonies,

was born on 10 May 1796 and educated for a military career; he obtained a commission in the horse guards, and was present as a staff officer at Waterloo. Leaving the army in 1830, he entered politics in 1831, but after one session left parliament also, and in 1837 was made lieutenant-governor of Prince Edward Island, and transferred in 1841 as governor to the Leeward Islands, where he built up a reputation for conciliating the colonists. Consequently, when the colonial office found that the politicians of New South Wales were growing restive under the able but stern rule of Gipps, FitzRoy was at once thought of as the obviously suitable successor, and in August 1846 reached Sydney and took up the reins of government—which he proceeded to hold very slackly. The personal popularity that naturally resulted from this was increased by popular sympathy with the governor on account of a distressing accident—the bolting of his carriage horses down the drive from the old government house at Parramatta, on 7 December 1847—which killed his wife and made him a cripple for many months. Retiring from his post on 17 January 1855, he settled down in London and died there on 16 February 1858.

FitzRoy himself was by no means a strong character, but in his term of office a strong governor would have done great harm. To students, looking back on those days in the light of what has happened since, it is clear that a good deal of excellent advice was given by the Imperial authorities, and Australia would have benefited if that advice had been followed; yet any attempt—such as Gipps would certainly have made—to insist on obedience to British authority would have driven the politicians and people of New South Wales to extreme measures, possibly to a declaration of independence. FitzRoy's part in moulding Australian society into fitness for responsible government is well defined by Rusden (*History of Australia* ii. 433):—

> With Wentworth controlling the bulk of the elected members—and desiring to form as close a copy of English institutions as circumstances permitted—with Deas Thomson suave and astute, loyal to the Queen and to the Governor, and patriotic as a colonist—with Sir Charles Fitzroy ready to assume responsibility when necessary, but content to leave the man who bore the brunt of battle to conduct the campaign in his own manner so long as principles decided on in the executive council were kept in view—the public men of New South Wales were gradually inured to parliamentary methods.

Nor was the exercise of his tact and conciliatory powers confined to Australia. His handling of the somewhat doctrinaire Earl Grey, while the latter was secretary of state for the colonies in 1846-52, was mainly responsible for the drastic modification of that politician's schemes, which in their original state would have produced endless friction and possibly worse. Here too it is probable that the guiding hand was that of Deas Thomson; but the governor deserves credit for knowing when to follow a good guide, and for supporting him steadily throughout. FitzRoy's term was crowded with events and problems. The anti-transportation agitation, the demand for the separation of Victoria, the claim for and devising of a new constitution in all the Australian colonies, the discovery of gold and the consequent disruption of the older (squatters') social regime, all fell within his period and had to be handled under his supervision. To deal with the constitutional questions, and to secure as much uniformity as possible without coercing the various colonies concerned—probably also to provide machinery for a scheme of Australian federation which Earl Grey much desiderated and local politicians much disliked—FitzRoy was on 3 January 1851 made governor-general of all the Australian colonies; this position, it was explained, was not intended to give him powers of general interference with their administration, but would provide him with a 'general authority to superintend the initiation and foster the completion of measures calculated to promote the common welfare.' It was, indeed, probably suggested by a despatch of his own (of 29 September 1846) advocating the appointment of 'some superior functionary . . . . to whom all measures adopted by the local legislatures affecting the general interests of the mother country, the Australian colonies, or their intercolonial trade, should be submitted by the officers administering the several governments before their own assent is given to them.' (Kt. Bach., 1837; K.C.B., 1854.)

Five-corners, a name given to the fruit of several species of *Styphelia* (q.v.). They are succulent drupes, with a sweetish pulp and a relatively large 5-angled stone containing five seeds; small boys appreciate them, and the aborigines in many districts use them for food. The best-known of the species are *S. viridis* and *S. triflora*.

Flagellariaceae, a small family of plants of which the only indigenous representative is *Flagellaria indica*, also widely distributed over tropical regions of Asia and Africa. It is a tall climber. The branches at the base are enclosed by the leaf-sheaths; leaves ending in a spirally twisted point which acts as a climbing tendril; flowers white, in clusters; fruit a small, nearly globular, drupe. Leichhardt, in his *Overland Journey to Port Essington*, says that his bullocks fed heartily on this plant, particularly as the country was most wretched and the grass scanty and hard. The stems are made into walking-sticks. The leaves are said to be astringent.

Flame-tree, the popular name for *Brachychiton acerifolius*, a large tree usually found in coastal brush forests, and confined to New South Wales and Queensland. The deeply lobed leaves are shiny, and fall before the tree flowers. It produces masses of bloom of a vivid scarlet; as the stalks of the bell-shaped flowers are also coloured, the result is a flame-like display which suggests the popular name. The flowering period is very irregular; in some instances the trees bloom for several consecutive years, but an individual tree may not produce flowers for several years. It is also known as the 'lace-bark tree.' When the tree is full-grown, the bark is fully 2 inches thick, and furnishes bast of a beautiful lace-like texture. The fibre is prepared by simple steeping, and is suitable for cordage, nets, mats, and baskets. It is also a good material for paper-making. The tow is of an elastic nature, suitable for upholstery, e.g. stuffing mattresses.

Flannel-flower, the popular name of *Actinotus helianthi*, a stout erect perennial herb of 1-2 feet, covered with a dense clothing of woolly hairs. The flowers are numerous, small, on short slender stalks, collected in a dense umbel and radiating from the top of the common flower-stalk, forming a convex button-like

head, resembling a daisy; calyx deeply divided

Flannel-flower.

into narrow, hairy, transparent lobes; petals obsolete; fruit flattened, covered with silky hairs; leaves twice tripartite, the usually obtuse segments again lobed. The spreading, woolly-white flannel-like bracts surrounding the umbel —often mistaken for petals—accentuate the likeness, and the flattened, hairy fruits contribute to the illusion. Its botanical name was given it by the early French botanist Labillardière. It extends from Gippsland in Victoria to southern Queensland, and is particularly abundant in the coastal districts of New South Wales. The plant is difficult to propagate; many of the seeds are infertile, and a few which germinate do not respond to cultivation. Seedlings taken from the bush rarely thrive. The plants are subject to a deformity known as 'fasciation,' which produces a banded or ribbon-like growth of the stem. They also occasionally break into a prolific floral growth, as in the 'Hen and Chickens' daisy.

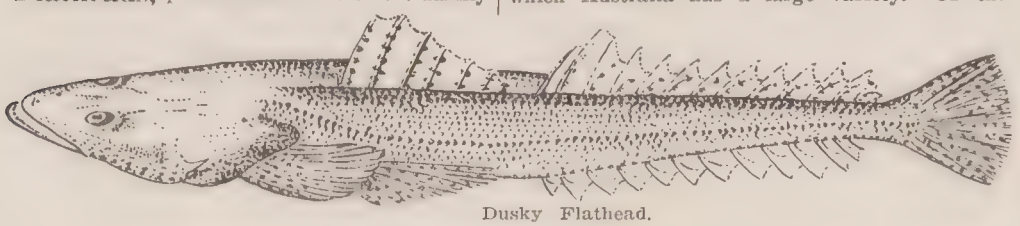
Flatheads, prized table-fishes of the family Platycephalidae, represented by over 30 species in Australian waters. They derive their name from the greatly depressed and expanded head, which is always considerably wider than the body, and is armed with spines capable of inflicting painful wounds. Being 'bottom' fish, they bury themselves in mud or sand, leaving only the upturned eyes exposed as they lie in wait for their prey. Their colour harmonizes with their environment, and the lower jaw projects forward in advance of the upper, so that the capacious mouth is directed upward and in the best position to snap up a crab or small fish unfortunate enough to approach.

Flatheads range from the shallows down to the depths, and are taken by line, hauling-nets, and trawlers. Those occurring in our cooler waters belong to the typical genus *Platycephalus*, but most of the tropical species are members of an allied genus (*Insidiator*) which is distinguished by the form of the teeth. In some the scales are minute, while in others they are large and rough. Their colours vary from the muddy-brown of the Dusky Flathead (*P. fuscus*) to an assemblage of beautiful lilac and mauve tints wonderfully variegated as in the Rock Flathead (*Thysanophrys cirronasus*) which harmonize with the weed-covered rocks among which the species lives. The Tiger Flathead (*Platycephalus macrodon*) is captured in large quantities by trawlers in deep waters, and is covered with small scarlet spots on a greenish ground-colour. Each State has its common local species, and all find a ready sale in the markets.

The spiny flatheads (family Hoplichthyidae) are distinguished by a row of stout bucklers with central spines along each side of the body. The head is greatly flattened and expanded, and the eyes are of large size to enable the fish to see in the dark depths they inhabit. *Hoplichthys haswelli* is plentiful in water of a depth of about 150 fathoms, where it is taken by trawlers; notwithstanding its forbidding appearance, it is a good food-fish. A.R.McC.

Flat-worms, the vernacular name of 'worms' (so-called) of the phylum Platyhelminthes, which includes the liver-flukes, tapeworms, and their allies. They are characterized by the formation of their alimentary canal—which opens anteriorly by a mouth, but ends blindly within the body—and by the absence of a body-cavity, the whole interior being packed with parenchymatous tissue. The phylum is divided into three classes—Turbellaria, Trematoda, and Cestoda; the last two are discussed under LIVER-FLUKES and TAPEWORMS.

Turbellaria are usually flattened and leaf-like in form, and move chiefly by means of minute protoplasmic processes (cilia) on their outer surface, which are capable of lashing forwards or backwards. From an Australian point of view the most interesting group of Turbellaria is that of the land planarians (q.v.), of which Australia has a large variety. Of the



Dusky Flathead.

marine forms *Diplosolenia*, a chocolate form with red and white margins, attains a length of two inches and a width of 1½ inches; *Leptoplana* is known to oyster-growers as 'the wafer,' and is accused of attacking oysters. In rivers and lakes forms belonging to the genera *Dendrocoelum* and *Mesostoma* are of common occurrence. A number of marine and several freshwater Turbellaria have been described by Haswell (see papers in the *Quarterly Journal of Microscopic Science* and in the *Journal* of the Linnean Society of London). L.H.

Flax. *Historical.*—Governor Phillip's instructions included a direction to attend to the cultivation of 'the flax-plant which is found in the islands not far distant from the intended settlement'—obviously the New Zealand flax (*Phormium tenax*) which Banks in 1770 and Matra in 1783 had noticed and praised highly. Phillip, however, mistook for the *Phormium* a much slenderer, reed-like plant (*Gymnostachys anceps*) which the Port Jackson natives used for making fishing-lines. This he found difficult to cultivate, as the natives pulled up the plants before they seeded. Some English flax-seed was also brought out, but seems to have failed. Hunter in 1798 applied for a fresh supply of seed; King took great trouble with the consignmeat that followed, and also experimented with a native flax-plant (*Linum marginale*, a relative of the European species) which was found growing in profusion on the banks of the Hawkesbury. In 1801 nearly 650 yards of linen was manufactured from the English plants. By 1804 nine looms were at work, and the output was 100 yards weekly; linen, sacking, and sailcloth were all manufactured. Marsden (q.v.) devoted a large area of his Hawkesbury lands to the cultivation of flax and hemp. Gradually, however, as methods of preparing and spinning the product of the New Zealand flax-plant were discovered and improved, the European plant fell out of favour. In 1810 Macquarie offered bounties for its local cultivation, but the demand was too limited to induce cultivation even with the aid of the bounty. Moreover, as the wool industry developed and prospered, woollen goods largely superseded linen. In 1824 a certain T. A. Curtis put before Lord Bathurst elaborate proposals for re-establishing the flax industry, and 369 barrels of seed were sent out for experiment; but the seed arrived in poor condition ('only one grain out of 150 retains its germinating principle') and at the wrong time of year, and—as Brisbane pointed out—it was lack of demand, not improper methods of cultivation, that had destroyed the industry already.

In Tasmania the first settlers found growing along the Derwent 'a great abundance of Grass . . . . which produces a Sort of Flax'—probably *Gymnostachys*; but nothing was done with it, and when many years later (in 1826) Arthur asked for a supply of flax-seed, Bathurst quoted the result of the Curtis shipment, and refused to try again.

Commercial.—In recent years (since about 1898) flax has been intermittently cultivated in Gippsland, and attempts have been made to introduce it to New South Wales and Tasmanian farms. From 1907 to 1917 the Commonwealth offered a bounty of ten per cent of the market value on all products of Australian-grown flax, but without apparent effect. During the war, however, the supply of flax from the Baltic provinces of Russia—which practically met the world's demand—almost disappeared, partly because Germany occupied the flax-growing districts, partly because the Bolshevik authorities seized all the seed for food purposes; the army council in England, therefore, agreed to purchase the 1918 Australian flax-crop at £170 per ton of fibre, and the Commonwealth authorities thereupon offered a bounty of £5 per ton (1918, 1922) and £6 (1919-21), and appointed a flax-industry committee to administer an act which provided *inter alia* for financing the establishment of mills to treat the flax-hay wherever grown in sufficient quantities to warrant it. This act expired in 1921, but was extended to cover operations in 1922. The results are shown in the following table:—

	Acres under cultivation.	Seed produced.	Fibre produced.
1917-18	419	1337 cwt.	925 cwt.
1918-19	1420	5200 „	3800 „
1919-20	1611	4970 „	1053 „
1920-21	993	3658 „	938 „
1921-22	918	4687 „	440 „
1922-23	590	3450 „	435 „

Up to the middle of 1922 the whole of the commercial flax crop was grown in Victoria (mostly near Geelong), but in the 1922-23 season 125 acres were planted in New South Wales, in the Albury and Twofold Bay districts. Flax sent to England in 1920 realized £325 per ton.

Flax cultivation in Australia is adapted to local conditions, the crop being harvested with a reaper and binder at a comparatively late stage of development, and the seed maturing while the sheaves are still in the field. The method of treatment is known as 'dew' retting: the straw is spread in thin layers over the paddock and thus exposed to the action of sun and dew.

Fleas, insects of the order Aphaniptera (or Siphonaptera), numbering a few species only, but cosmopolitan in habitat and all parasitic upon either mammals or birds. They are characterized by the highly-specialized piercing mouth-parts, the shape of the body (laterally, not vertically, flattened), and their great leaping powers, as well as by the absence of wings through degradation. The Aphaniptera are related to the Diptera, of which order some entomologists consider them only a sub-order; but it seems best to consider them a separate order that arose, probably, either from the very base of the Diptera or from the older order Mecoptera.

The flea's life-history is interesting. The eggs are laid either on or off the host; the larva is an elongated, legless grub, much resembling that of one of the mycetophilid Diptera. Larvae of fleas infesting the cat and dog are capable of nourishing themselves on the refuse and dust accumulated in an unswept room, and rapidly reach maturity. The pupa is enclosed in a light silken cocoon, and is of the *pupa libera* type.

About 30 species of flea are known in Australia. The fleas common in houses are either the world-wide *Pulex irritans*, or *Ctenocephalus canis* and *C. felis* (the dog- and cat-fleas), or *Ctenopsylla musculi* (the mouse-flea); all these take equal pleasure, apparently, in biting man and their normal hosts. The rat-flea (*Ceratophyllus fasciatus*) is abundant, as also the tropical rat-flea (*Xenopsylla cheopis*), the latter being the species instrumental in the spread of bubonic plague.

Of the species peculiar to Australia a number belong to the genus *Stephanocircus*, and are parasitic on various marsupials. The most interesting form is the peculiar *Echidnophaga ambulans*, whose host is the echidna. *Parapsylla australica* occurs on the little blue penguin. The largest flea yet found in Australia is *Pygiopsy la rainbowi*, found on the water-rat.

N. Rotschild added considerably to the number of species known in Australia. R.J.T.

Flies. The classification and natural history of these insects will be found under DIPTERA; here their economic importance as malignant or beneficent agents is discussed. As in other orders of insects, comparatively few of the indigenous Diptera are serious pests, most of the troublesome ones having been introduced.

Fruit-flies.—The most serious fruit-pests in Australia are the Mediterranean Fruit-fly (*Ceratitis capitata*) and the Queensland Fruit-fly (*Chaetodacus tryoni*). The former appeared in Western Australia in 1896; by 1899 the Swan River district was so badly affected that it was difficult to obtain a single sound peach or orange, and most of the softer apples and pears were attacked. It is now also a serious pest in eastern Australia; in Victoria and Tasmania, owing to the vigilant action of the official entomologists, it was quickly exterminated; it has not as yet appeared in South Australian orchards, but an unceasing watch is kept for it, and every year maggot-infected fruit is destroyed at ports of entry in the three States mentioned. The mature flies puncture ripening fruits, and in the small hole made lay a batch of about ten eggs. Sometimes many flies oviposit in the same fruit, so that the inside soon becomes a mass of squirming maggots. No effective and cheap controls are known. Kerosene has a powerful attraction for the males, but little for the females, and is therefore not of much use. Fly-papers, sprays, and poisons are also employed. In some Mediterranean districts the more valuable oranges are protected by enclosing each in a paper bag; in Western Australia and parts of Africa whole trees are enclosed in mosquito-netting or hessian. Gathering and destroying fallen fruit, and (where possible) picking unsound fruit, help to minimize the trouble. In Western Australia efforts to cope with the pest by the introduction of parasites (notably from Brazil) ended in complete failure. Many local insects attack the maggots after they have left the fruits—ants and carabid beetles being often in evidence—but no parasite of any importance has yet been found. There are several broods in a season, and in some districts it is difficult to obtain sound fruit of the later sorts. The fly attacks a wide range of fruits, even including the prickly pear and native berries.

The Queensland Fruit-fly (*Chaetodacus tryoni*) is very troublesome in northern Australia, India, and elsewhere. Sydney appears to be its most southerly range, but in this region it may disappear for years. This fly works its mischief very much as does the Mediterranean fly, but attacks a greater variety of fruits. In Queensland it infests many solanaceous berries and wild fruits, particularly guavas (which are victims of two other species as well); it is for this reason, probably, that the pest is so widely distributed in that State. Bananas especially are damaged, and have to be prematurely picked to avoid infection. In berries and the smaller wild fruits the maggots are often destroyed by small ichneumon parasites; but in the larger fruits the maggots live so far below the skin that parasites have very little chance against them. A vigorous outlook is being kept to prevent its introduction into hitherto uninfested States; fortunately it appears able to live only in warm climates.

Other fruit-flies are known, but are of less consequence.

The Tomato-fly.—The tomato in many parts of Australia is more or less seriously attacked by the 'blue' tomato-flies (*Lonchaea aurea* and *L. rugosifrons*) small, brilliantly metallic species about half the size of the Mediterranean fruit-fly. The maggot is about the same length, but much thinner; it is often mistaken for the other. The fruits are usually attacked long before they are ripe.

Ferment-flies.—Decaying fruits and other fermenting vegetable matter—grape must, vinegar, sour beer, etc.—are often seen to be swarming with small, yellow, red-eyed flies. These are ferment-flies, of which *Drosophila ampelophila* is the commonest species. The maggots are sometimes so abundant that alarm has been caused by confusing them with fruit-fly larvae. They do not, however, attack sound fruit.

Leaf-miners.—The introduced Marguerite or Cineraria Fly (*Phytomyza nigricornis*) is now almost universally distributed in Australia, and the white tunnels of its larvae may be seen in leaves of many kinds of plants, especially among the Compositae. A smaller native species (*Phytomyza betae*) attacks the beet, and will probably in time become a serious pest of the sugar-beet. In Western Australia its larvae are sometimes seen drilling the leaves of several poisonous plants.

Bean-fly.—A minute black fly (*Agromyza phascoli*) attacks the stems of beans in Queensland and New South Wales, and often kills the young plants; but its larvae and pupae are destroyed by a great variety of small parasitic Hymenoptera.

Useful Flies.—Aphides are commonly attacked by syrphid larvae; the curious thick-ended (and usually pale-green) blind maggots may be seen amidst clusters of aphides, and one will impale an aphis, hold it in the air till it is sucked dry, and then with a tremulous motion wave its head-end about till it can impale another specimen. This process may be continued for days. Unfortunately the larvae are themselves severely parasitized by small ichneumon and chalcid wasps. One of the commonest of the useful species is *Syrphus viridiceps*, which occurs in all the Australian States. Several curious forms live in the nests of *Iridomyrmex* ants (q.v.).

Many tachinid flies are parasitic on larvae of moths and butterflies; others attack locusts. *Locustivora pachytili* (which is now usually referred to the Sarcophagidae) is very useful in this respect. Very small flies of the Phoridae are parasitic on beetles in the adult stage, and others destroy their larvae; some species also infest cockroaches and other troublesome insects.

House-fly.—The house-fly (*Musca domestica*), of almost universal distribution, is the best-known instance of an insect that was formerly considered unimportant though annoying, but is now known to be one of man's most serious enemies, and largely responsible for the distribution of typhoid, tuberculosis, infantile diarrhoea, sandy blight, and ophthalmia—even,

occasionally, for the transmission of yaws and anthrax. These flies breed very largely in stable manure; and, as the female lays an average of 120 eggs, and in summer a generation may be produced every ten days, they soon become superabundant. Hence in cities it is now a common recommendation that manure be thrown into air-tight receptacles till it can be removed, or covered with lime or other fly-deterrents. Much of the mortality in past wars, and amongst permanent armies in India, is believed to have been due to these formerly despised creatures. They cannot pierce flesh, but their tongue has a slight rasping arrangement by means of which they can extract moisture; and, being especially attracted by cuts and sores, they easily infect their victims. In the drier parts of Australia this fly and the allied 'cattle' or 'bush' fly (*Musca vetustissima*) are incessant and irritating pests.

In 1912 Harvey Johnston discovered in these two flies, and in the Stable-fly (*Stomoxys calcitrans*), minute nematode worms which in the previous year had been shown by H. B. Ransom to be the larval stages of a species of *Habronema*, a parasite found in the stomach of the horse. In 1916-8 the work of Bull in Adelaide and of Lewis and Seddon in Victoria proved that this parasite caused granulomatous sores and inflamed eyes in horses, and possibly also the 'swamp cancer' known in the Northern Territory. G. F. Hill in 1918, and Harvey Johnston and M. J. Bancroft in 1918-20, published careful investigations into the life history of *Habronema* which confirmed the earlier results, and showed that each fly was host to a particular species of the parasite; those harboured by *M. domestica* usually infect stabled animals, but *M. vetustissima* is responsible for the transmission of equine granuloma to stock out of doors. The subject is fully treated in the *Proceedings* of the Royal Society of Queensland for 1919 and 1920 and the *Memoirs* of the Queensland museum for 1920. See BLOOD-SUCKING FLIES and BLOWFLIES. **A.M.L.**

Flinders, MATTHEW (1774-1814), son and grandson of surgeons, was born at Donington in Lincolnshire on 16 March 1774, educated first at the Donington free school and later at the Horbling grammar school, and designed by his father to follow the family profession. But the boy read *Robinson Crusoe*, and the course of his life was altered. Against the wish of family and friends he determined on a naval career. His father's consent was reluctant, and the advice of his uncle John Flinders, who had served 11 years in the navy and was not yet a lieutenant, was naturally discouraging. Matthew, however, was undeterred, and applied himself to the study of mathematics and navigation; through a cousin who was governess to the daughters of Captain Pasley he obtained an introduction to that officer, who entered him in H.M.S. *Alert* as lieutenant's servant on 23 October 1789 and seven months later (on 17 May 1790) took him under his own charge in the *Scipio* and—as midshipman—in the *Bellerophon*.

He saw no real service until the following year, when he entered upon a voyage which determined his future work. William Bligh (q.v.) was fitting out a second expedition—that of the ill-fated *Bounty* having been the first—to convey bread-fruit trees from the southern Pacific to the West Indies. An opportunity presenting itself of joining H.M.S. *Providence*, the ship selected for the purpose, Flinders with Captain Pasley's consent took it. The expedition was successful, and its educational value for the young midshipman was great. Bligh, a fine sailor, found Flinders's theoretical knowledge of navigation very useful, and employed him in the preparation of charts, the making of scientific observations, and the care of the chronometers and other instruments. From this voyage dates the definite hankering after exploration, the successful prosecution of which constitutes Flinders's principal claim to remembrance. When the *Providence* returned in 1793, Flinders again served under Pasley in the *Bellerophon*, and took part in the great action off Brest on 1 June 1794, when Howe inflicted a severe defeat on the French navy. The fifth lieutenant of the *Bellerophon* was Henry Waterhouse; he at the conclusion of the campaign was promoted to the command of H.M.S. *Reliance*, then being got ready to convey the second governor, John Hunter, to New South Wales. Flinders, eager for experience, and hoping to find in Australia scope for the kind of work he was most anxious to do, joined the *Reliance*, and sailed in her in February 1795. The ship's surgeon was another young man from Lincolnshire, George Bass (q.v.).

The exploratory work of Flinders—commencing with a cruise in the *Tom Thumb* in company with Bass, including the demonstration that Australia and Tasmania were separated by a strait, and concluding with the circumnavigation of the continent in the *Investigator*—is treated elsewhere (see EXPLORATION BY SEA). Here only biographical facts need be noted. Flinders secured his lieutenancy in 1797 returned to England in the *Reliance* in 1800, and was promoted commander in 1801. The admiralty was just then, under the influence of Sir Joseph Banks, fitting out a ship for exploration of the southern shores of New Holland. The *Xenophon* was chosen and renamed *Investigator*, and Flinders's previous services (and the friendship of Banks) secured him the command. He sailed in July 1801, resolved, as he wrote to Banks, 'that no person shall have occasion to come after me to make further discoveries;' and few men in maritime history have combined eminently unsparing devotion to an arduous task with such great practical skill and scientific knowledge.

On 7 December he reached the Leeuwin and commenced his detailed survey of the southern coast; on 8 April 1802 he met Nicholas Baudin, captain of a French exploring ship, *Le Géographe*, in Encounter Bay; on 9 May he reached Port Jackson, but started north on 22 July, examined the coast up to the Percy Isles and from Cape York to Arnhem Bay in the Northern Territory, and was then (March 1803) forced by the condition of his ship to run for Timor, make what repairs he could, and return hastily to Sydney round the western coast of Australia, reaching Sydney again after a perilous voyage on 9 June. From this time onwards he plunged into a series of misfortunes that made the later phases of his career little less than tragic. Wishing to take to England without delay the charts he had compiled, and finding the *Investigator* quite unseaworthy, he accepted a passage in the *Porpoise* and sailed on 10 August, intending to make for Batavia by the Torres Straits route. A week out from Sydney the vessel was wrecked on a reef in

the open ocean about 230 miles north-east of Sandy Cape in Queensland. Flinders organized a miniature colony on the reef, fitted up the *Porpoise's* cutter, and made his way back to Sydney; but Governor King, though keenly sympathetic with one whom he much admired, could give him no better a vessel than the *Cumberland*, a locally-built 29-ton craft, in which to make the best of his way home to England. To a seaman of Flinders's skill and courage the difficulty did not seem insuperable. He sailed on 21 September, again taking the passage through Torres Straits, reached Timor in October, and thence made sail to cross the Indian Ocean. The leaky condition of the ship gave constant trouble, and the pumps, worn by constant use, became unserviceable; Flinders therefore felt compelled to make for Ile de France (Mauritius), in order to get the schooner caulked and the pumps refitted before attempting the passage round the Cape of Good Hope. Ile de France was then a French colony, administered by General Charles Decaen, an officer who had won his rank during the wars of the Revolution, and whose soldierly qualities had attracted the quick eye of Napoleon. Flinders at the time of his arrival was not aware that war between England and France had again broken out. Had he known this, however, it is probable that he would still have sought assistance; for he bore a passport from the French government, and the usage of nations was understood to protect from hostile treatment vessels engaged on scientific service. But the misfortune which had pursued him since the abandonment of the *Investigator* reached its climax in Ile de France. As he was making for port, on 15 December, a French schooner ran before him, and reported on her arrival that she had been chased by an English ship; consequently a certain element of suspicion attached to him from the outset. At Baie du Cap, the port of arrival, the military force had been called out, and after a little delay a French officer came off to the *Cumberland* and demanded Flinders's passport. It was then seen that the document was made out, not for the *Cumberland*, but for the *Investigator*—a circumstance which, in the officer's eye, made it necessary that Flinders should give an explanation to the governor. At the first examination Decaen, apparently suspecting that Flinders was a spy, questioned him with a view of discovering from his answers whether his pretensions were *bona fide*. Consequently, when after the examination he sent an officer to invite Flinders to dinner, the latter, resenting the treatment to which he had been subjected—and not making sufficient allowance for the anxieties of a general charged with the duty of defending a colony thousands of miles from sources of supply and reinforcement, and in daily dread of attack from a British fleet—refused the invitation. Decaen in his turn resented this behaviour. A contemporary manuscript history of Ile de France (now in the Bibliothèque Nationale at Paris) describes Flinders as showing 'much impertinence' and 'arrogance,' whereas Decaen, according to the same writer, 'received him in uniform bareheaded,' and was disposed to listen patiently to his explanation. From this time onwards, at any rate, Decaen's disposition was harsh, and he resolved not to deal with the case himself, but to send a statement of the facts to Paris in order that the will of the government might be pronounced, in the meantime detaining Flinders as a prisoner. In 1806 Napoleon ordered Decaen to set him at liberty, but the general took the responsibility of not acting upon the instruction, explaining that he deemed the prisoner too 'dangerous' to be allowed to go. The evidence shows that he believed Flinders, during the years of his detention, had acquired too much information about the defences of the island to make it prudent to let him go. The malevolence which has been attributed to Decaen was not a characteristic of his. Flinders himself, who certainly had no particular reason for thinking kindly of him, testified that he bore 'the character of having a good heart, though too hasty and violent.'

The statement has been frequently made that during Flinders's detention his papers and charts were seized by the French, and dishonestly used in the preparation of the atlas illustrating the history of Baudin's expedition. For this charge there is not a tittle of evidence. Flinders made no such accusation; and a careful examination of the French charts affords not the slightest warrant for assuming that those who prepared them ever saw any of Flinders's material. It is true that his papers were taken from him, and sealed up; some were restored to him, at his own request, during his imprisonment, in order that he might occupy his time with the preparation of his charts; Decaen kept one log-book, because it contained entries showing why Flinders called at Ile de France; and the remaining papers he received back on his release, intact (according to his own testimony) except a few that had been eaten by rats.

On 13 June 1810 Flinders was released, and reached England on 23 October. For the remainder of his life he was chiefly occupied with the writing of his book—*A Voyage to Terra Australis*—and with the preparation of his charts. In a modest footnote in his book he suggested the name 'Australia' for the continent (see AUSTRALIA, NAMING OF). He died on 19 July 1814, at the age of 40, leaving a widow and one daughter in somewhat straitened circumstances: the first copy of his book had been delivered at his house on the previous day, but he was too ill to see it.

It cannot be said that he was liberally treated by the admiralty. Had he returned to England in 1804, he would have been promoted to the rank of post-captain. His detention in Ile de France cost him not only loss of health and great distress of mind, but also six years' extra pay; and the exigences of his work upon the charts and the book involved four years' personal expenditure of £200 a year in excess of his income. In 1852 the governments of New South Wales and Victoria granted to his daughter, Mrs. Petrie, a pension of £200 a year, and continued to pay it for 40 years—an honourable recognition of Australia's debt to one of the foremost, bravest, and ablest of her maritime explorers. E.S.

In 1901 Professor (now Sir) W. M. Flinders Petrie, grandson of the navigator, presented to the public library of Victoria transcripts from early journals (e.g. that of the boat-voyage of 1796) and a letter-book covering the period 1807-14. About 20 years later Sir Flinders Petrie agreed to present the rest of the Flinders papers in his possession to whichever of the Australian States would erect a suitable memorial to the explorer. New South Wales promptly offered to put up a statue, and the papers—which include two volumes of the *Investigator's* log

(1801-3), three letter-books, and Flinders's private diary from 17 December 1803 to 10 July 1814—were handed over to the State government and purchased by the trustees of the Mitchell Library, the purchase money defraying the cost of the bronze statue of Flinders by the late W. R. Colton, R.A. The sculptor died after executing the model but before the statue was cast.

See Flinders's own *Voyage to Terra Australis* (2 vols., London, 1814) and Scott's *Life of Captain Matthew Flinders* (Sydney, 1914). In the *Naval Chronicle* for 1814—vol. xxxii—there is a biographical sketch of the navigator based largely on material supplied by himself; and a valuable collection of his letters is reprinted in vols. iii-vii of the *Historical Records of New South Wales*. The *Voyage de Découvertes aux Terres Australes*, by Péron and Freycinet (Paris, 1807-17), gives the official account of the relations between Flinders and Baudin; the latter's diary is in the Bibliothèque Nationale at Paris, and many unpublished despatches in the Archives Nationales. Prentout's *L'Ile de France sous Decaen* (Paris, 1901) gives an account of Flinders's captivity in the Mauritius founded on the Decaen papers; these are preserved at Caen, and the documents relating to Flinders are as yet unpublished.

Flindersia, a genus of the family Rutaceae, endemic in Australia, consisting of trees with small flowers and large, elongated, capsular fruits covered with rough tubercles. The seeds are flat and winged. There are 16 species, all eastern. *F. australis* (Native Teak) is a coastal brush tree 100-120 feet high, ranging from northern New South Wales to Queensland. The fruit, owing to conical tubercles on the shell, is known as rasp-pod. The timber is hard and of great strength and durability, not discoloured by iron, and shrinks but little in drying; hence it is excellent for railway purposes. *F. Oxleyana* (Yellow-wood) is also a coastal brush tree in New South Wales and Queensland. It reaches a height of 100 feet, with a diameter of 3-8 feet. The timber is largely used in the frame-

Leopard Tree.

work of railway carriages and waggons, and is said to fill the place of English or American ash. A military board has decided that it is the most suitable Australian wood for ammunition boxes. The wood yields a yellow dye. *F. maculosa* (Leopard Tree, so called from its spotted trunk) is a small tree (20-30 feet), found in the dry interior from New South Wales to Queensland. In its early stages it is a tangled mass of long thin branches which, though not prickly, form a hedge, so that stock can prune but do not destroy the plants. Later a leading shoot emerges, protected by the encircling tangle of branches, which gradually atrophy; this main shoot develops into the trunk of the tree. In some cases the mass of branches persists for a long time near the ground; in others the branches at the ground level die off; or the whole of the early growth may disappear, leaving a clean barrel. It is an excellent fodder-plant, but requires careful pollarding, as its recuperative powers are not great It exudes a gum, which forms good adhesive mucilage, is pleasant to taste, and is eaten by the aborigines. This is a common bushman's remedy for diarrhoea.

Flounders, flatfishes of the family Pleuronectidae which, with the soles, differ from all others in having both eyes on the same side of the head. They are commonly confused with soles by fishermen, who apply both names indiscriminately to the same or to closely allied species. Flounders are characterized by having the margin of the preoperculum free and exposed, instead of hidden beneath the skin. One species (*Ammotretis rostratus*) is called 'sole' in Victoria and Tasmania, but is more correctly known in the Sydney markets as 'long-snouted flounder.' Several species of the genus *Pseudorhombus,* known as the large-toothed, small-toothed, and deep-sea flounder, find a ready sale in the markets, being delicate fishes for the table; unfortunately not enough of them are caught to supply the demand. Several species of the genus *Rhombosolea* are forwarded to the southern markets, where they are sold at a high price. The so-called Queensland Halibut (*Psettodes erumei*) has considerable economic potentialities, but has hitherto been taken in small quantities only by trawlers. It is a fine, fleshy fish, attaining a length of about two feet, and is one of the few flatfishes in which colour occurs as often on the left side as on the right. Its upper eye is close to the margin of the head.

Young flounders are bilaterally symmetrical, with an eye on each side of the head, and swim in an upright position. But at a very early stage of development they fall over upon one side, and the eye which then becomes the lowermost moves round towards its fellow, and distorts the skull in doing so. Normally the upper side alone is coloured, the lower being whitish; but individuals are occasionally encountered in which the lower surface is partly or entirely coloured like the upper. A.R.McC.

Flower-pecker. See MISTLETOE-BIRD and DIAMOND-BIRD.

Flycatchers, small perching birds with broad (sometimes very broad) bills surrounded by bristles, belonging to the family Muscicapidae. Birds of this family are confined to the eastern hemisphere, and are numerous in Australia. Though the typical members of the family are easily recognized by the characters mentioned, so many forms are intermediate between the flycatchers and the warblers, thrushes, and shrikes, that the limits of the family are

quite arbitrary, and every author has his own view as to what birds should be included in it. In this article only the more typical members will be treated—the species known in the vernacular as flycatchers and fantails. Fly-eaters, robins, thickheads, and other birds often placed among the Muscicapidae, will be dealt with separately.

Flycatchers, as their name implies, are insectivorous birds; they usually select perches from which they can watch for passing insects, flying out and catching them in the air and then returning to the same or another perch to repeat the operation. As they prey chiefly on the smaller day-flying insects, they must be counted among the most valuable of our birds, ridding us of great numbers of flies, mosquitoes, and other pests.

One of the most familiar species throughout a great part of the continent is the Brown Flycatcher (*Microeca fascinans*), familiarly known as 'Jacky Winter.' It is also called Peter-Peter, as its loud and cheerful call strikingly resembles these words repeated a number of times. But the best known is the Black-and-white Fantail (*Rhipidura leucophrys*), universally called 'Willy Wagtail.' This familiar bird frequents open bush country throughout Australia, but does not occur in Tasmania. It seems specially to delight in the neighbourhood of man and his domestic animals. Its song—which, though simple, is quite pleasing and is generally translated as 'Sweet pretty creature!'—it utters constantly during the day and frequently on moonlight nights. The wagtail's popularity is largely due to his bold and inquisitive nature. He is a constant attendant on all happenings about the homestead, perching on fence or gate or the ground, constantly wagging his long tail from side to side and springing up into the air to catch any insects that may be disturbed. When nesting he becomes especially daring, making vicious darts at the heads of human beings or animals that approach his chosen tree, and driving away birds much larger than himself should they have the audacity to settle in it or fly too near it.

The pretty little White-shafted Fantail (*Rhipidura flabellifera*) is one of the few small birds

Rufous Fantail.

found both in Australia and New Zealand. Like its larger relative the wagtail, it is a tame and inquisitive bird; but, instead of wagging its tail, it flutters about in the air, or among branches, with fan-like tail spread to its full extent. The lovely Rufous Fantail (*Rhipidura rufifrons*) has similar habits, but is much more retiring, inhabiting scrub and forest country.

The Restless Flycatcher (*Seisura inquieta*) bears considerable resemblance to the wagtail, but has no black on its throat. Its chief peculiarities are its habit of hovering in the air, and its curious harsh note, like the sound pro-

Restless Flycatcher.

duced in grinding tools on a wheel—whence it derives the name of 'scissors-grinder.' This note is frequently uttered, not only while hovering, but also when settled.

The remaining flycatchers on the Australian list are mainly birds of the tropical scrubs, and hence confined to the coastal districts of the north and east. The best-known are the Leaden Flycatcher (*Myiagra rubecula*) which migrates south to Tasmania, and the Black-faced Flycatcher (*Monarcha melanopsis*), which reaches Victoria. The most remarkable is the Boat-billed Flycatcher (*Machaerirhynchus flaviventer*), a little bird which has an enormously broad bill. It only comes south as far as Cardwell in northern Queensland.

Flycatchers construct beautifully neat cup-shaped nests of fine vegetable material, covered externally with spiders' webs. Those of the fantails (not including the wagtail) are further remarkable in the possession of a tail or stalk projecting downwards below the branch or twig on which the nest is placed. This appendage, which is variable in length, is generally left in a ragged condition, contrasting with the neat structure of the nest itself. About its object various suggestions have been made. Some authors maintain that it is for the purpose of making the nest less obvious and more like a casual collection of debris; others hold that it serves to increase the stability of the structure; a suggestion has also been made that is serves to drain off moisture. W.B.A.

Fly-eaters and Tree-tits, very small arboreal and insectivorous birds peculiar to the Australian region, belonging to the genera *Gerygone* (including *Pseudogerygone*) and *Smicrornis*. These genera are now usually placed

among the flycatchers (Muscicapidae) but seem to have equal or better claims to a position among the warblers (Sylviidae).

Both fly-eaters and tree-tits build domed nests, suspended either in bushes or among the twigs of trees. The nests are remarkable in possessing a projection over the entrance, forming a sort of hood or porch. Those of the fly-eaters have in addition a tail or appendage beneath, like those of the fantails (see FLYCATCHERS). They feed almost entirely on minute insects, in search of which they hop actively about among the foliage, meanwhile constantly uttering their songs—some of which take high rank in Australian bird-music, while all are pleasing. In the Australian bush they occupy the position filled by the wood-warblers (Mniotiltidae) in North American forests, and by warblers ('willow-wrens') of the genus *Phylloscopus* in European woods.

The Short-billed Tree-tit (*Smicrornis brevirostris*) has the distinction of being the smallest Australian bird. It is fairly common in southern Australia, but keeps largely to the tree-tops, so that it is little seen. The White-throated Fly-eater (*Gerygone albogularis*) of south-eastern Australia is a charming little song-bird, often

Bush Canary.

called 'bush canary'—not altogether inappropriately, as it has a bright yellow breast. In southern Queensland the same term is often applied to the Singing Fly-eater (*Gerygone cantator*), which chiefly inhabits mangrove belts along coastal creeks. The Brown Fly-eater (*Gerygone richmondi*) is common throughout south-eastern Australia. The Western Fly-eater (*Gerygone fusca*), very common in south-western Australia, is there sometimes called 'singer.' With regard to this species it must be noted that Gould (q.v.) gave it the name *fusca* before he knew its habitat, and then in error transferred that specific name to the brown fly-eater of New South Wales, calling the Western Australian species *culicivora*. The original name is now officially restored to the western bird, and the eastern bird receives the name of *richmondi*.

W.B.A.

Flying-fishes, species of the family Exocoetidae, many of which occur in all temperate and tropical seas; about a dozen are known from Australian waters. They attain a length of 16 inches, and are excellent table-fish. They have the habit of leaping from the sea and skimming above its surface at great speed for distances up to several hundred yards, probably to escape the attacks of enemies; in order to maintain the weight of the body while in the air their pectoral fins are greatly enlarged, and the ventral fins also may be considerably expanded. It is uncertain whether flying-fish actually fly by moving their 'wings' at great speed, or whether they merely glide; it is probable that both methods are employed, since the relative sizes of the fins vary greatly in different species. The initial impetus is gained from the tail-fin before the fish leaves the water, and a flight is often prolonged if the tail touches the crest of a wave as the fish speeds over it. Flying-fish move in shoals near the surface of the sea, and are greatly preyed upon by larger fish and dolphins in the water, and by birds in the air. They are frequently attracted by the lights of ships at sea, and fly aboard at night, shattering themselves against the ironwork as a result of their velocity. This habit of flying toward a light is known to the natives of many parts of the South Seas, and they erect in their canoes a net or sail to catch the fish, which they attract with torches at night. See also GURNARDS.

A.R.McC.

Flying Foxes. See BATS.

Flying Opossums—also known as 'flying phalangers' and (rather confusingly) as 'flying squirrels,' a name properly belonging to a family

Flying Squirrel.

of true squirrels that has no representatives in Australia—are diprotodont marsupials of the family Phalangeridae, provided with a parachute in the shape of a fold of skin that extends between the fore- and hind-limbs and, when stretched by the extension of these limbs, enables the animal not actually to fly, but to glide obliquely downwards through the air as do the true flying squirrels.

The largest, the Greater Flying Opossum (*Petauroides volans*), is almost as large as the common opossum. It has long, soft, silky fur varying from black to ashy grey or creamy white above, white or yellowish below; large oval ears, hairy on the outside; hands and feet thickly fringed with black hairs; the tail prehensile, grey or blackish, with the lower surface naked for a short distance at the free end. The greater flying opossum is, apart from its power of 'flight,' very similar in habits to an ordinary opossum. It is found throughout

eastern Australia from Victoria to Queensland, and is by no means rare, but is seldom seen unless specially hunted for; during the day it remains concealed in hollows in dead trees, and at night seldom descends to the ground. Its food consists of buds, leaves, and twigs.

The Yellow-bellied Flying Opossum (*Petaurus australis*), which inhabits the coastal ranges of New South Wales and Victoria, is much smaller than *Petauroides volans*, though still of considerable size, the head and body being 12 inches long, the tail 13 inches. It has long fur, brown on the upper surface, and variously marked with orange and black; the under-surface is orange. The long tail is very bushy, especially at the base.

The Squirrel-like Flying Opossum (*Petaurus sciureus*) is distinctly smaller, the head and body being only about 10 inches long, and the tail about 11 inches. It occurs over a wider range from Queensland to Victoria. It has soft, silky, slightly woolly fur, pale grey above—with a distinct band of black or brown along the middle of the back—and white with a tinge of yellow below. The Lesser Flying Opossum (*P. breviceps*) has a wider range, extending into Arnhem Land; it is distinguished from *P. sciureus* by its smaller size, shorter fur, and other minor differences. A still smaller allied species, *P. papuanus*, occurs in New Guinea.

The Pigmy Flying Opossum (*Acrobates pygmaeus*) is a minute, mouse-like creature, the smallest representative of the phalangers. The head and body together are three inches long, the tail about the same; the body is covered with a soft, silky fur, greyish-brown above, yellowish-white below. The flying membrane is fringed with long hairs. The tail is fringed on each side with a row of strong hairs, giving it a feather-like appearance; the under-side of the tip is naked. *Acrobates* feeds on leaves, buds, and fruits, with an occasional insect; like its allies, it is nocturnal, and lies concealed during the daytime in a nest constructed of leaves in a hole in the trunk of a tree. Though seldom seen unless specially sought after, it seems common enough in forest country in Queensland, New South Wales, and Victoria.

Nearly related to the flying opossums of the genus *Petaurus*, but devoid of a flying membrane, is Leadbeater's Opossum (*Gymnobelideus leadbeateri*)—a rare form, the only known specimens of which have been obtained on the Bass River in Victoria. The striped opossums (*Dactylopsi'a*), which similarly lack a flying membrane, are also closely related to *Petaurus*; they range from New Guinea (*D. trivirgata* and *D. melampus*) to central Queensland (*D. picata*). Their general colour is white, with black longitudinal stripes. A long-fingered form, *Dactylonax palpator*, also occurs in New Guinea.

The Feather-tailed Opossum (*Distoechurus pennatus*) is a near relative of *Acrobates*, but is devoid of the flying membrane, and is of distinctly larger size. It occurs in Papua. See MARSUPIALS. W.A.H.

Flying Pieman, THE. See KING, W. F.

Fodder-plants. Besides the native grasses (which are dealt with separately) Australia has many useful fodder-plants, some of which have not yet received the attention that is their due. The best-known is the saltbush (q.v.), a name applied somewhat indiscriminately to salsolaceous plants of six genera, one of which (*Rhagodia*) is endemic in Australia. Many wattles (*Acacia*) are valuable fodder-plants; some are becoming rare because stock eat down the seedlings. *A. aneura* (Mulga), sometimes called the 'king of fodders,' occurs in all the mainland States. *A. doratoxylon* (Spearwood or Carrawang) grows in all the States except Tasmania and Western Australia. *A. implexa* (Hickory) occurs in the three eastern States. *A. pendula* (Myall, called also Boree in southern New South Wales), extends also to Queensland, and is a great stand-by for sheep in dry seasons. *A. salicina* (Native Willow, Cooba, or Motherumba), now becoming scarce, occurs in all the mainland States. The portulaca family, including the genera *Calytonia* and *Portulaca*, are succulent spring and summer plants; *P. oleracea* (Pigweed), which the aborigines called 'munyeroo' and used for food, is readily devoured by stock. Among the Leguminosae, besides the wattles already mentioned, the Darling pea (*Swainsona*) and its relatives are nutritious and palatable, but appear at certain seasons to develop injurious narcotic qualities; they are therefore discussed under NOXIOUS PLANTS. A very useful legume is *Trigonella suavissima* (Menindie Clover), which is found throughout the interior of the continent from the Murray River to Shark Bay. Among the edible eucalypts are the Sugar Gum (*Eucalyptus corynocalyx*).

The Sapindaceae of fodder value include the Cattle-bush or Whitewood (*Atalaya hemiglauca*), Hop-bush (*Dodonaea lobulata*) and Rosewood (*Heterodendron oleaefolium*), but the last-named occasionally secretes excessive amounts of prussic acid in its leaves.

From the Cruciferae we have several species of *Brennodia*, particularly *B. lasiocarpa* (Mustard-plant), which affords good feed in the spring and early summer, and the widely distributed pepper-plants (*Lepidium*). The Geraniaceae are represented by the Native Crowfoot (*Erodium cygnorum*), a valuable spring fodder which the first hot wind scorches out of existence, and the Native Geranium (*Geranium dissectum*), which is less prolific. The Tar-wine (*Boerhaavia diffusa*), a valuable drought-resistant summer herb, much appreciated by stock, belongs to the Nyctagineae. The Meliaceae provide two good fodder-trees, *Flindersia maculosa* (Leopard-tree) and *Owenia acidula* (Native Nectarine or Emu Apple); and the Myoporaceae two more, *Myoporum platycarpum* (Dogwood) and *Eremophila longifolia* (Emu-bush). Among the Rutaceae occurs the Wilga (*Geijera parviflora*) a small umbrageous tree common in the inland pastoral country, which is so closely cropped by sheep as to become a symmetrical and even artistic feature in the landscape. Other useful trees or shrubs are Butter-bush (*Pittosporum phillyroides*), found in all the States and a good stand-by in time of drought; Native Currant (*Apophyllum anomalum*); Supplejack (*Ventilago viminalis*); Quandong (*Fusanus acuminatus*); and Belah (*Casuarina Cambagei*). Useful herbs not yet mentioned are the Native Carrot (*Daucus brachiatus*), a comparatively small plant, but palatable, nutritious, widespread, and available in the early spring; Rib-grass (*Plantago varia*), valued for its medicinal qualities, abundant in all the States, and especially common in association with *Danthonia* and *Stipa* pastures (see GRASSES); Hairy-head (*Ptilotus*) and Nardoo (*Marsilea quadrifolia*). E.B.

Football. Australia holds a probably unique position in the world of sport in that it is the home of four well organized codes of foot-

ball. In general terms the number might be reduced to three, since the Rugby League game is just as much 'Rugby' as the Rugby Union, though the Rugby League game requires fewer players and is maintained on a professional basis. The two other forms are the Australian game, and British Association (commonly known as 'Soccer'). The Australian game is popular in all States except Queensland and New South Wales, the Rugby Union strongest in New South Wales and Queensland (which has, however, adopted the League form in the last few years), and Rugby League and Soccer in New South Wales.

The Australian Game.—The first press notice of football in Australia appeared in the Sydney *Monitor* of 25 July 1829, where it is referred to as 'an amusement of the military' and 'much played in Leicestershire.' It is known that football was played in some form or other in the forties, but the first real effort to establish order in the control of the game appears to have been made in Melbourne in 1858, and included startling innovations in the rules recognized in England. The pioneers of the game were H. C. A. Harrison, W. Hammersley, J. B. Thompson, and T. W. Wills, an old Rugbeian; Harrison, a famous athlete in his day, is still living and actively interested in both football and cricket. These gentlemen founded the Melbourne Football Club, which was soon followed by the establishment of clubs at Richmond and South Yarra. Little interest, however, was taken in the game, which was from all accounts dangerous and brutal; hacking (i.e. deliberately kicking at an opponent) and tripping were not offences. Rough as football is to-day, there are fewer physical dangers in the game than there were at this early period. The rules were few, and the players' uniforms nondescript. Between 1858 and 1866 many clubs were formed, and it became obvious that some system must be agreed on. Accordingly on 8 May 1866 delegates from the leading clubs met to formulate rules for the Australian game; these rules, with a few minor changes, are substantially those which govern it to-day. The delegates were H. C. A. Harrison and R. W. Wardill (Melbourne), the former acting as chairman; G. O'Mullane and H. Murray (South Yarra), B. James and T. Power (Carlton), and J. E. Clark and R. Chadwick (Royal Park). At this meeting the distance between the goals was increased from 170 to 200 yards, and running with the ball was limited by a regulation that it must be bounced every five yards (a distance afterwards increased to ten yards). In 1869 the practice of deciding a match when two goals had been obtained by either side, in however brief a time, was altered to the present system of fixing a time-limit for the game. In 1872 a further conference ordained the change of sides at half-time, and insisted that all disputes on the field should be referred to a field umpire. In 1876 the Victorian Football Association was formed with W. T. Clarke as president, H. C. A. Harrison and R. Robertson as vice-presidents, H. H. Budd as secretary, and T. P. Power as treasurer. But the Association was never really popular, and in 1897 the Carlton, Collingwood, Essendon, Fitzroy, Geelong, Melbourne, South Melbourne, and St. Kilda clubs broke away and formed what is now known as the Victorian Football League, which because of its strength became the controlling body in Victoria. The Association still exists, the outer suburbs being represented on it.

From Victoria—which has always been its headquarters—the Australian game has gradually spread to Tasmania and South and Western Australia, where it has pride of place. In New South Wales the game has never been popular. An attempt made in 1878 to interest Sydney in the new game gained a few supporters, mainly because a team from Carlton had visited Sydney in 1877 and played an exhibition game with a team of Rugby players. In 1880 Victorians living in New South Wales succeeded in fixing a match between Rugby players and 'old Victorians' at Moore Park, and in the following year two clubs (Sydney and East Sydney) were formed and a team sent to Melbourne. A second team went to Melbourne in 1886, and the game was witnessed by 12,000 people. The Melbourne authorities did what they could to foster the game in Sydney by sending teams over, but enthusiasm ebbed steadily, and in 1897 the game ceased to be played. In 1903 it was revived, and League teams from Collingwood and Fitzroy played one of their premiership matches in Sydney; soon afterwards the New South Wales Football League was formed, and in 1912 obtained a large ground of its own at Botany. No official inter-State matches have been instituted, but since the war teams representative of Victoria and New South Wales have exchanged visits twice a year, and teams from other States also visit Sydney. In 1907 a league playing under Victorian rules was founded in Queensland, but progress there has been slow.

The first intercolonial match was played between Victoria and South Australia on 1 July 1879, when Victoria won by 7 goals 14 behinds to 3 behinds. The two States now exchange visits yearly, and in 1925 a Victoria-Western Australia annual match is to be instituted. Since 1908 triennial championship matches have decided State supremacy in the Australian game. In 1908 Victoria won the championship at Melbourne, in 1911 South Australia at Adelaide, in 1914 Victoria at Sydney, in 1921 (after an interval due to the war) Western Australia at Perth, and in 1924 Victoria at Hobart.

In 1897 the laws of the game were revised, and since then very few alterations have been made. The game is played with 18 men a side; the playing space is maximum 200 yards by 150, with a minimum of 150 yards by 100 yards; four quarters of 25 minutes each constitute the time of play; change over is made at the close of each quarter, and a rest of 15 minutes is permitted at half-time; there is no offside, and as soon as the ball goes out of bounds it is thrown in by a boundary umpire. Consequently the game is very fast.

Rugby Union.—In 1870 the first steps were taken to form in New South Wales a football club under Rugby rules. Five enthusiasts—R. A. Arnold, W. M. Arnold, T. Brown, Septimus Stephen, and G. Deas Thomson—formed the Wallaroo club, which within a short time was followed by the University, Burwood, St. Leonards, and The King's School clubs, and two years later by Waratah, Newington College, and Calder House clubs. The chief difficulty at first was to get a suitable ball to play with, the proper ball being unobtainable; a saddler, however, made a clumsy ball which did good service until one in accordance with regulations could be procured from the maker in England. Teams consisted of 20 players, and all disputes were settled by the captains. In 1874 delegates from the Wallaroo, The King's School, Newington College, Goulburn, Waratah, Balmain, North Shore, University, and Camden College formed the Southern Rugby Union. The

Rugby Union of England code of rules was adopted; J. J. Calvert became the first president of the Union, T. Brown (Wallaroo) and E. Barton (University) vice-presidents, and W. H. Fletcher treasurer and secretary. By 1880 the number of clubs had reached 100, and the game flourished everywhere. The Wallaroo club began to play 15 men a side, and very soon the practice was adopted by all clubs. The first intercolonial match under these rules was played between New South Wales and Queensland on 12 August 1882 at the Sydney cricket ground in the presence of 4000 people, and was won by New South Wales by 28 points to 4. In August 1882 a team from New South Wales visited New Zealand under the captaincy of E. Raper, and won four of the seven matches played. Since that year visits have been interchanged by teams from Australia and New Zealand, and inter-State matches between New South Wales and Queensland have taken place annually. In 1889, 1894, and 1895 Victorian teams visited Sydney but were only once successful in winning a game. Since 1895 Victoria has had no organized Rugby football. Some attempt has been made to establish the game of late years, but Rugby has no hold in Victoria.

International Football.—In 1888 the first British team under Rugby rules visited Australia; of nine games played in New South Wales seven were won and two drawn (against The King's School and the Sydney Grammar School). The captain of this team, R. L. Seddon, was during the tour drowned in the Hunter River, and the captaincy devolved on A. E. Stoddart, later and better known as a cricketer, who thus had the unique distinction of captaining an English team against Australia in both cricket (1894-5 and 1897-8) and football (1888). Four matches in Queensland and one in Melbourne were won, the visitors scoring 58 points to 15 in all. Of matches under Australian (then known as Victorian) rules seven were won and 12 were lost. In 1899 M. Mullineux—whom A. B. Paterson has celebrated in verse—brought out a team whose play set its Australian opponents a fine example and helped to raise considerably the standard of local football. A third team, under D. R. Bedell-Sivright, visited Australia in 1904, and a fourth (Harding's) in 1908. In 1908-9 the first Australian team to go abroad visited England and America; it was known as 'The Wallabies,' and comprised H. M. Moran (captain), Frederick Wood (vice-captain), W. Dix, C. Russell, H. Daly, J. Hickey, F. Bede Smith, E. Mandible, D. B. Carroll, A. J. McCabe, C. H. McKivat, Ward Prentice, J. M. Stevenson, J. T. Barnett, M. McArthur, E. McIntyre, T. Griffin, C. A. Hammond, P. H. Burge, A. B. Burge, P. A. McCue, S. A. Middleton, C. McMurtrie, N. E. Row, C. E. Murnin, P. Carmichael, C. E. Parkinson, T. J. Richards, F. Flanagan, K. Garvan and R. R. Craig. The team was defeated by a Welsh team (1 penalty goal and 2 tries to 2 tries), but defeated an English team (3 tries to 1): no Scotch or Irish players having been chosen in Harding's team, the Rugby Unions of Scotland and Ireland held aloof from the Australians' return visit, and matches were confined to England and Wales. Thirty-one matches in all were played, of which only five were lost (those against Llanelly, Midlands, Wales, Swansea, and Cardiff). Five matches played in America were all won, but the tour was a failure financially, the Union losing some £1400.

In 1910 a team from the United States visited Australia, but were beaten in five out of the eight matches played. The advent of the Rugby League, which is described below, deprived the Union game of a good deal of popularity, and during the war (1914-18) all official games were suspended, so that when in 1919 Union football recommended it was found very difficult to rearouse public interest; but the events of the 1924 season show that much of its old-time popularity has been regained.

Rugby League football originated in 1907 from a dispute within the Union as to the adequacy of the allowance for out-of-pocket expenses; the Union at that time allowed to players on tour only 3s. per day, and several popular players demanded more, and went on to suggest that payments should be made even for matches in the home town on the lines of the English Northern Union arrangement. This at once raised the whole question of professionalism, and a Rugby League was formed which agreed to pay its players 10s. per day and 7s. 6d. for out-of-pocket expenses. The Union authorities thereupon declared all League players professionals, and expelled them. A similar movement had already split New Zealand football, and a team from the Dominion visited Sydney in 1907 and won three games against the new League's team. In 1908 a League team ('The Kangaroos') of 34 players, with D. Lutze as captain and H. H. Messenger as vice-captain, visited England, where it won 18, lost 22, and drew 6 matches. A second team visited England in 1911 under the captaincy of C. McKivat; the tour was a financial failure, but of 35 matches 28 were won, 5 lost, and 2 drawn. In 1910 a Northern Union (England) team came out under J. Lomas, and won 8 matches, lost 4, and drew 1. A team from New Zealand visited New South Wales in the same year, and in 1912 a New South Wales team visited New Zealand, winning 8 out of 9 games. In 1920 an English team under H. Wagstaffe toured Australia, and in 1924 one under J. Parkin. The first match of Wagstaffe's team against Sydney drew a record 'gate' for a Rugby match —67,739 spectators, producing £5740. The League has spread from New South Wales into Queensland, where it has almost entirely displaced the Union game.

Among the more important changes in play introduced by the League are the abolition of two forward players (reducing the team to 13), the prohibition of kicking out of touch on the full, and an increased stringency with regard to off-side play round the scrum. In 1923 it was further ruled that no goal could be obtained from a mark, and that the touch judge may intervene in the progress of a game if he wishes to report foul play to the referee.

British Association (Soccer) football was first played in Australia in 1880, when the game was introduced to Sydney and the New South Wales Association was formed. It gradually spread to the other States, and its progress since the war has been rapid. In 1923 there were 450 Soccer clubs in New South Wales, with a playing membership of 7000; Victoria had 24 clubs, South Australia 21, and Queensland 21 in the Moreton Bay area alone. The governing body is the Football Association (Australia), on which all the States are equally represented. In 1921 an Australian team visited New Zealand, winning two test matches and drawing one; in 1922 a New Zealand team visited Sydney and won two out of three test matches. In the same year a team of Chinese university students (with a few

other Chinese) visited all the States except Western Australia; of five test matches the visitors won one and lost three, one being drawn. In 1923 a Canadian team visited the four eastern States, won two test matches and lost three, the sixth being drawn. Australian Soccer is played under British rules, but a local additional rule in New South Wales allows the replacement before half-time of an injured player, provided the consent of the referee and the captain of the opposing team has been obtained. J.V.C.-B.

Forbes, Sir Francis (1784-1841), born at St. George in the Bermudas in 1784 and educated in his native town, went to England at the age of 19, was admitted to Lincoln's Inn on 26 May 1806, and called to the bar in 1812. In 1813 Lord Bathurst made him attorney-general of the Bermudas, and in 1816 he became the first chief justice of Newfoundland. Having satisfactorily established the new judicial system in that colony, and finding the climate too severe for a long stay, he in 1822 returned to England on leave and was offered by Bathurst the chief justiceship of New South Wales. He was repeatedly consulted during the preparation of the New South Wales judicature act (4 Geo. IV, cap. xcvi), was appointed chief justice on 1 June 1823, and received his formal commission on 13 October. Five months later, on 13 March 1824, he landed at Sydney, promulgated the charter of justice on 17 May, and on the same day took his seat on the bench and opened the new supreme court. He had already (on 1 December 1823) been appointed a member of the legislative council, and on 20 December 1825 became a member of the executive council also. These were more or less political positions, which conflicted with his position as a judge; and the conflict was emphasized by the bestowal on him of an exceptional power with regard to legislation, against which he had protested vigorously before leaving England. As chief justice he was required, before any bill was submitted to the legislative council, to certify that it was not, in his opinion, inconsistent with the laws of England. This requirement, as he himself said, gave him a power of veto over proposed legislation.

During Brisbane's administration there was no friction between governor and chief justice; but Darling held strongly the view that his councillors—and Forbes as one of them—ought to support his policy. Forbes, holding aloof from politics and exercising his power of veto with strict conscientiousness, was soon brought into collision with the governor. In July 1825 the colonial office directed Darling to introduce a bill for licensing the colonial press, as an indirect method of reimposing a censorship on it. When the bill was submitted to Forbes for his certificate, he considered its terms inconsistent with existing English law, and recommended that it be submitted to the British parliament, which alone could alter existing law. Darling in December 1826 accepted this recommendation; but when Forbes early in 1827 refused his certificate to a bill imposing a stamp duty on newspapers, and the local press in some way (certainly not from Forbes himself) obtained this news and used it as a weapon against the governor, Darling grew restive. During the year he attacked the chief justice bitterly in despatches; but the colonial office was in 1827 under three different ministers, and the despatches (as well as letters from Forbes setting forth his side of the case) were not dealt with until Sir George Murray assumed office in May 1828. Murray on the advice of his law officers decided (*a*) that Forbes was right as regarded the licensing bill, but probably wrong—though conscientiously so—as regarded the stamp bill, (*b*) that in regard to several minor complaints both parties had made mistakes, (*c*) that if the dissensions continued he would recall both the judge and the governor, and (*d*) that, as a matter of high policy and without reflecting on Forbes personally, the chief justice must cease to be a member of the executive council.

Forbes meanwhile had persistently held himself aloof from partisanship of any kind, and had actively supported Darling where he saw a just occasion—e.g. he denounced the attacks on the governor in the case of Sudds and Thompson (see Darling, Sir R.) as 'a political juggle.' In April 1829 there was a formal reconciliation between governor and judge, but the unofficial friction continued until Darling's departure in 1831. Forbes's health had never been good, and was sadly impaired by the long controversy; even Bourke's friendship and support could not restore the failing strength. In 1835, finding that he could not get through a single term's business without serious illness, he obtained leave of absence, but delayed his departure for six months to obviate a dispute between the two puisne judges as to which of them should officiate as chief justice in his absence. In April 1836, yielding to the persuasions of Bourke, he sailed for England; but the delay had been fatal, the disease (which involved paralysis of the left arm) fastened on him and proved incurable, and in May 1837 he resigned his post and was granted a retiring allowance of £700 a year. In 1838, after appearing as a witness before the parliamentary committee on transportation, he returned to Sydney, and died there on 9 November 1841.

His name is inseparably connected with the introduction into New South Wales of trial by jury in the ordinary sense of the word. The act of 1823 ordained the establishment of courts of quarter sessions, and Forbes in October 1824 decided that this involved the summoning of juries. The local magistrates, whose duty it was to frame lists of jurymen, confined themselves to free settlers and officials, omitting the names of all emancipists. Brisbane in 1825 was inclined to advocate the admission of emancipists, but forbore to do so officially, and Darling opposed the suggestion vehemently. It was not, therefore, until Bourke's advent that Forbes could have his way; but in 1833 he and the other judges (Dowling and Burton) decided that all free persons, whatever their former state, were entitled to all the privileges of free men. Forbes's excellence as a judge is eulogized by Roger Therry (q.v.), who ascribes to him (*Reminiscences*, p.335) 'judicial qualities of a high order—imperturbable calmness of temper, acute discrimination, and a thorough acquaintance with legal principles,' adding instances of his 'masterly analysis of evidence.' His interest in education took active shape in his work towards the founding of the Sydney College; and his value to the colony as a citizen is best shown by Bourke's declaration to Roger Therry after his death:—'If I had any success in removing abuses and opening the way to a better course of government in the colony, to the assistance I received from Forbes I am mainly indebted.' (Kt. Bach., 1837.) See Judiciary.

Forest Mint. See Mentha.

Forestry. Except for extensive areas of soft-woods in Queensland and Tasmania—and, to a less extent, in the coastal belt of New South Wales—the natural Australian forests consist of hard-woods. The principal forest areas occur in the eastern and southern portions of the continent, in Tasmania, and in the south-western area north and east of Cape Leeuwin. In the main these forests are mountain products. In Queensland they lie between the seaboard and the Great Dividing Range, and on the crests and slopes of the mountains. In New South Wales the wide plains of the Murrumbidgee, Lachlan and Darling districts are bare, but the rest of the State is wooded, the largest timber being found on the coastal slopes. Owing to the extent of its mountain territory and its ample rainfall, Victoria is one of the best-wooded of Australian States. Except on peaks above the winter snow-line the mountains are well-covered; thin forests extend also across the northern plains, and belts of red gum occur along the course of the Murray and in the valleys of its tributaries. The Otway and Gippsland districts, south and east of the main divide, are also luxuriantly wooded. Forest areas in Tasmania are widely distributed over the island, soft-woods being found chiefly in the western and southern districts. In South Australia the forests, less luxuriant than those of the eastern States, are restricted to the hills surrounding Adelaide and the Yorke and Eyre peninsulas. In Western Australia there is a forest-belt stretching from the Leeuwin north to the Murchison River and east to Albany; jarrah forests extend eastward from the Darling Range, and in the north-west the King Leopold and St George's ranges are well-covered. The rest of the State is bare. Small forests also occur in the Northern Territory and round the Gulf of Carpentaria.

No complete survey of state forest lands has been made on a uniform basis, but it is estimated that the total forest area approximates 69,054,000 acres, only 3.63 per cent of the total area of the Commonwealth. There are no means of determining the original forest wealth of Australia, but doubtless much of it has been destroyed in the process of settlement. It has been estimated, for example, that the forests of New South Wales, which now cover 11,000,000 acres, extended 100 years ago over 30,000,000 acres. During the early years of settlement some protection against indiscriminate destruction was afforded to the forests in the interests of the British navy, all timber suitable for naval purposes being reserved in early land-grants to the Crown. In 1795 Governor Hunter was moved to take action against the destruction of the forests in the Hawkesbury district; he forbade the felling of timber on ground not marked out or allotted to individuals, and again ordered that no trees marked as suitable for the navy should be cut. The first recorded shipment of timber on a large scale for use 'in His Majesty's dockyards' was made in 1804. But with the close of the Napoleonic wars the timber requirements of the British navy were reduced; the pressure of settlement was already making itself felt, and henceforth the interests of forestry throughout Australia were entirely subordinated to those of settlement. Additional destruction was occasioned by the unregulated activities of timber-getters. In 1824 Governor Brisbane directed the attention of the colonial office to the advantage that would accrue to settlers if they could find a market abroad for Australian timbers—a fact which local merchants had already recognized. By 1827 the governor found it necessary to charge ½d. a foot for cedar cut on crown lands to meet part of the extra cost of policing the cedar-cutters in the coastal districts of New South Wales, among whom great disorder frequently occurred. During the next 50 years the valuable red cedar forests of the continent's north-eastern coast were laid waste. In Western Australia, also, no adequate regulations controlled the activities of settlers, who exploited the jarrah and sandalwood belts to tide them over the years of unproductive agriculture.

Public interest in the conservation of forest resources seems not to have been aroused in Australia until 1871, when the initiative was taken by South Australia. During the next 40 years halting attempts were made to develop a forestry policy in the various States. In South Australia the government was requested in 1871 to furnish parliament with a return showing the supply, preservation and culture of forests in the colony; in 1873 it agreed to subsidize the planting of trees by landowners, and in 1875 a forest board was appointed and provision made for the reservation of forest areas. The forest board soon established small plantations of soft-woods, especially of *Pinus insignis*, which was first introduced into the colony by Baron von Mueller; but its activities were continually hampered by insecure tenure and lack of funds. It was not until 1903 that certain reserved forest areas were made inalienable except by vote of both houses of parliament. The need of trained forest officers led to the institution of a course in forestry at the university of Adelaide. In New South Wales the destruction of the red cedar forests on the north coast and the red gums along the Murray was such an obvious waste of valuable resources that the government in 1871 established a number of forest reserves in which timber should be cut only under licence; these reserves, however, could be easily revoked. A forest ranger was appointed in 1875, and in 1877 forest regulations were issued and a forest-conservation branch of the public service constituted for administrative purposes; but this branch was transferred from department to department in a way that made continuity of policy impossible. In 1889 a department of forestry was created, and a director-general of forests appointed; he was not, however, a trained forester, and administrative expenses far exceeded the forest revenue, with the result that the department was again reduced to a branch service. No active policy was adopted until 1895, when a trained forester was appointed to control the service; his powers were limited, and he was opposed by vested interests; but he was able to show that money well spent in the care and management of forests would be amply repaid. He aroused so much public interest that in 1907 a royal commission was appointed to examine into the forestry position. They recommended a vigorous policy of conservation and afforestation, and pointed out the necessity of adequate forestry legislation, better supervisory machinery, and the permanent dedication of approved forest lands. As a result a forestry department was again created and a forestry act passed in 1909; but the powers of the department under the act were very limited.

In Victoria the conservator of forests, who was appointed in 1887, tried without much success to prevent the alienation of good forest land

for settlement purposes; he was, however, able to establish some coniferous plantations, and soft-woods are now being cut in Victoria, as well as in South Australia, from forests thus planted. In 1907 the Victorian parliament passed a forestry act under which a forests department was created, with exclusive control of forest policy; the conservator was made directly responsible to a minister, and was given the management of reserved forests, timbered lands, plantations and nurseries. Provision was made for the reservation of permanent forest areas, inalienable except by special act of parliament; the training of forest officers was also provided for, and a school established at Creswick for primary training in forestry. Under the act working plans regulating the felling and output of timber from the reserves were put in force. An inspection of Victorian lands for demarcation purposes was made by the district surveyor and a forest officer jointly. Until 1916 the Victorian forestry policy was more advanced than that of any other State.

In Queensland a public meeting was held in 1873 to consider the question of forest conservation, and the government was induced to appoint a select committee to consider and report up the best means of preserving and promoting the growth of timber trees and of conserving forests for useful purposes; but the committee made only a few desultory recommendations, inadequate for the initiation of a continuous forest policy. A forest act of 1906 provided for the establishment of a forestry service, under a director of forests; the governor was empowered to reserve areas as state forests or national parks.

In Western Australia a forestry department administered certain regulations for the control of forests which were inserted in the land act of 1898. Under the act the government was authorized to reserve from sale any crown lands that might be required as forest areas, but the regulations did not specifically provide for forest management in any other way than by the issue of timber and other licences and leases.

In Tasmania, where the timber trade had been carried on actively since the forties, no effort was made to initiate a forestry policy until 1885, when a conservator of forests was appointed under the deputy commissioner of crown lands; he resigned his position after two years' service, and his place was not filled. The lands department thenceforth administered such forest regulations as were issued, especially those attached to the crown lands acts of 1903 and 1905. Timber reserves of an estimated area of 1,500,000 acres were proclaimed; the land could not be sold or used for settlement until the valuable timber had been removed, unless the reserve were revoked by a proclamation in the *Gazette*.

In 1911, after the States had been experimenting in forestry for 40 years, the responsible forestry officers decided to pool their experience by holding the first of a series of inter-State conferences. It was agreed that in none of the States was there forestry legislation comprehensive enough to ensure the conservation, maintenance, and planting of forests; that there was need for more adequate provision for the creation of permanent and inalienable reserves; and that management should be vested in a permanent authority endowed with statutory powers. Only in Victoria and South Australia had any provision been made for the training of foresters, and there was an obvious need for a more comprehensive educational scheme. Most States had acts providing for some degree of fire-protection, but it was generally recognized that these were inadequate. In order to secure the passage of further legislation necessary to carry out a vigorous and continuous forestry policy, it was resolved that an unofficial Australian Forestry Association should be formed 'to awaken the people and the several State governments to the enormous waste of forest resources and to the lack of effective provision for the requirements of the future.' As a result of this and subsequent inter-State conferences (held in 1912, 1916, 1917, 1920, and 1922), and of the public interest roused by the propaganda of the Forestry Association (formed in 1912) and by the direct inspiration of Sir Ronald Munro-Ferguson—a trained and widely-experienced forester who was governor-general in 1914-20—there has been a rapid advance in Australian forestry during the past decade. Comprehensive legislation has been passed or is under consideration in all the States. The first effective move was made in 1916 by New South Wales. The control of forest policy in that State was vested in a board of commissioners who, within the limits of their statutory power, were freed from political control; they were empowered to carry out a policy which they themselves were to devise, to reserve not less than 5,000,000 acres of crown land as state forests, and to spend on forestry improvements (exclusive of administrative expenses, which are voted by parliament) 50 per cent of the forest revenue. The commission, before laying down working plans, began a systematic organization of state forests and a survey of forest resources with a view to making permanent reservations. It is hoped that 5000 acres of coniferous plantations will be laid down annually for the next 20-30 years. A forest school has been established at Narara near Gosford, where a two years' course in scientific forestry is provided. Control of forest policy by a commission was adopted in Victoria in 1919. In Western Australia an expert was appointed in 1916 to reorganize the forestry department, and in 1918 was passed a forestry act on lines laid down by the inter-State conferences. In Tasmania a conservator of forests was appointed in 1919, and a separate forestry department was established; after the inter-State conference held in Hobart in 1920, a forestry act was passed, of a less comprehensive character than the Western Australian. In Queensland no legislation has been introduced since 1906; but an adverse report on the State's forestry policy made by Sir David Hutchins in 1915 resulted in great administrative improvements. In 1922 the inter-State conference was held in Brisbane, and the forestry officers and ministers there present pointed out the necessity for more up-to-date legislation in Queensland, on the lines now adopted in the other States.

The functions of forestry authorities in the various States include the care and management of natural forests, the exercise of strict control over the operations of timber-getters, and the provision of adequate fire-protection. In States deficient in soft-woods the departments are taking measures to establish coniferous plantations, the lack of which is seriously felt throughout the Commonwealth. In 1922-3 there were 134 acres of nurseries in Australia; 4412 acres of forest were planted during the year making the total area of effective plantations

47,359 acres, of which about 39,000 acres were in South Australia and Victoria.

Surveys of natural forest areas are also being made with a view to enlarging the permanent state forests. At the inter-State conference of 1920 it was estimated that to meet the future requirements of Australia 24,500,000 acres of forest would be necessary. This figure has since been adopted as the Australian forest ration, and the reservation of that area is now being expedited on the following basis of distribution:—New South Wales, 8,000,000; Victoria, 5,500,000; Queensland, 6,000,000; South Australia, 500,000; Western Australia, 3,000,000; Tasmania, 1,500,000. The area of state forests reserved in perpetuity totalled in June 1923 10,412,637 acres, of which 5,315,689 acres were in New South Wales, 3,401,738 in Victoria, 1,410,364 in Queensland (exclusive of the 153,540 acres of national parks), 203,258 in South Australia, 52,389 in Western Australia and 29,199 in Tasmania. In addition to the state forests each State maintains a number of timber reserves, which can, however, be easily cancelled. The area of these reserves in 1923 was 7,836,499 acres; the total area controlled by the forestry departments of the various States was 18,500,000 acres. This total includes inaccessible mountainous country and cut-over lands, whereas the agreed-upon quota only refers to merchantable forest.

Since 1911 forestry officers have been agreed upon the necessity of improved facilities for training foresters, and have favoured the establishment of an Australian school of forestry supported by the Commonwealth and State governments jointly. The Commonwealth has decided to establish this school in the Federal Capital Territory; its diploma course will be a two-year one, and will supplement and develop the training now given by the schools at Gosford in New South Wales, Creswick in Victoria, and Ludlow in Western Australia. An Australian forest products laboratory has already been instituted at Perth, with the aid of the Commonwealth government.

The revenue and expenditure of the various forestry departments in 1922-3 was:—

	Revenue	Expenditure
New South Wales	£168,698	£137,108
Victoria	163,076	138,714
Queensland	267,816	158,618
South Australia ..	8,362	40,822
Western Australia	87,658	38,827
Tasmania	19,346	8,293

Forrest, Alexander (1849-1901), born in Western Australia in 1849 and trained as a surveyor, came into public notice when he accompanied his elder brother John (q.v.) on his expedition from Perth to Adelaide via Eucla in 1870. In 1871 Alexander was entrusted with the leadership of a party selected to explore the country E. and S. of Hampton Plains. This and his other explorations are described under Exploration by Land. In 1874 he was second in command of John's expedition to the Murchison and Fitzroy, and other rivers, being specially selected for reconnaissance work in connection with the colonial survey. His most important exploration was undertaken in 1879, when he opened up the Kimberley district, 25,000,000 acres of which he reported suitable for pastoral development or tropical agriculture; a special land regulation was therefore issued in November 1879, and an immediate development of settlement took place. Thenceforth Forrest abandoned exploration for commercial and political work. In 1886 the newly-formed Kimberley electorate sent him to the legislative council, and in 1887 he was the acknowledged leader of the country protectionists, who demanded duties on the importation of live stock rather than of manufactures. He won the West Kimberley seat in the first elections under responsible government (1890), and represented his colony at the federal convention of 1891. He died in 1901.

Forrest, Baron. John Forrest, first baron Forrest of Bunbury (1847-1918), third son of William Forrest, was born on 22 August 1847, and educated at the Bishop's School at Perth in Western Australia. At the age of 18 he entered the colony's survey department, and in 1869 was given charge of an expedition into the interior to search for traces of the missing explorer Leichhardt. In 1870 he led an expedition from Perth along the Bight to Adelaide, and in 1874 traversed the colony from Champion Bay to the overland telegraph line between Adelaide and Port Darwin, a distance of over 2700 miles (for all these journeys see Exploration by Land). These services gained for him the gold medal of the Royal Geographical Society of London, as well as the title of Chevalier of the Order of the Crown of Italy, and honorary fellowship of the St. Petersburg, Vienna, and Italian Geographical Societies. He also received the thanks of the colonial government, and a grant of 5000 acres from the Imperial authorities. In 1876 he was appointed deputy-surveyor-general; in 1878-9 he was acting commissioner of crown lands and acting surveyor-general, in 1880-81 acting comptroller of government expenditure; from 1883 to 1890 he was commissioner of crown lands and surveyor-general, with a seat in the executive and legislative councils. With the introduction of responsible government (in securing which he took a prominent part) he became first premier and colonial treasurer of the colony, a position which he held without interruption for nearly 11 years, relinquishing office only to undertake wider duties in the first federal parliament. During his term of office notable gold discoveries were made in the colony, and a great expansion took place. To his strong purpose and wide outlook during this period are due the goldfields water scheme, the Fremantle harbour works, the development of the railway system to the mining areas, and the liberal land legislation of Western Australia.

He was a member of both federal conventions, that of 1891 and that of 1897-8; he also represented his colony in the federal councils of 1893-5-7-9, being president in 1897. In 1901 he was elected to the federal house of representatives for Swan, and retained the seat till his death. In the first federal ministry he held successively the positions of postmaster-general (1901) and minister of defence (1901-3); from September 1903 to April 1904 he was minister for home affairs, treasurer from July 1905 to July 1907, acting prime minister from March to June 1907, and treasurer again from June 1909 to April 1910, and from June 1913 to September 1914. When in 1917 W. M. Hughes formed a coalition ministry to carry on the war, Forrest was again treasurer, but retired in March 1918. In February a peerage had been conferred on him. He died at sea on 3 September 1918.

Forrest's great work was his development of Western Australia during his long premier-

ship. In the debates of the federal conventions he took part mainly as champion of the smaller colonies, and during his federal period remained a striking figure, but scarcely an active deviser of policies or a progressive administrator. Indeed, his value as treasurer was mainly due to his conservative tendencies. The transcontinental railway from Port Augusta to Kalgoorlie, which he had advocated before the Commonwealth came into existence, he thereafter continued to advocate as the one sure link between the eastern States of the Commonwealth and their isolated western partner. In England he was well known and popular. He made official visits at both Queen Victoria's jubilees, at the coronation of Edward VII and at that of George V, and shared in the honours distributed on those occasions. (C.M.G., 1882; K.C.M.G., 1891; P.C., 1897; G.C.M.G., 1901.)

Forster, JOHANN REINHOLD (1729-1798), descendant of a Yorkshire cavalier family that settled in Polish Prussia after the death of Charles I, was born at Dirschau near Danzig in 1729, and in 1754 was Lutheran minister at Nassenhuben. In 1765 he abandoned the ministry for a scientific career, visited Russia, and in 1766 settled in England as assistant-master at Warrington school in Buckinghamshire; in 1770 he moved to London (at the suggestion of Alexander Dalrymple) and embarked on literary work, translating in 1772 the Comte de Bougainville's *Voyage Round the World*. In the same year he was made a fellow of the Royal Society and joined Captain Cook's second expedition as naturalist, taking with him his son Georg to make the necessary drawings. On their return the two published the result of their researches as *Characteres Generum Plantarum* (1775). The plants on which this was based were given to Sir Joseph Banks, and are now in the British Museum. It had been intended that Forster should write the account of the second voyage as Hawkesworth had that of the first; but difficulties (mainly temperamental) cropped up, and in the end Cook wrote the book himself, Forster being forbidden by the admiralty to write anything. He therefore set Georg to work, and his account was published in 1777 a few months before Cook's appeared. This breach of discipline ended the Forsters' English career, and they returned to Germany. From 1780 to 1798 Reinhold Forster was professor of natural history and director of the botanical gardens at Halle; he also translated and edited for German consumption the Pacific voyages and journals of Cook, White, Bligh, Hamilton and Hunter. After his death in 1798 his library was acquired by the royal library at Berlin.—His son JOHANN GEORG ADAM FORSTER (1754-1794), already mentioned (better known as George Forster), was born at Nassenhuben on 27 November 1754. He accompanied his father to the Pacific, and in 1776 was made a fellow of the Royal Society for his share in the *Characteres*. His drawings of animals and plants made during the voyage were in 1776 purchased by Banks for £400, and are in the British Museum. He seems, however, to have made many duplicates, and had at least 30 redrawn in London by a more skilful artist for presentation to George III; a good many of these came into the possession of Cook's cousin Isaac Smith (q.v.), and are now in the Australian Museum at Sydney. In 1778, just before leaving England, he published *A Letter to the Right Honorable the Earl of Sandwich*, which set forth fully and with some virulence the Forsters' side of the quarrel with the admiralty. After his return to Germany Georg was professor of natural history at Cassel (1778-84) and Wilna (1784-8), and in 1788 was made custodian of the library at Mayence. In 1786 he published a treatise on the edible plants of the South Sea islands, and in 1790 toured western Europe with Alexander von Humboldt; in 1793, France having advanced her boundaries to the Rhine, he was sent as deputy from Mayence to the national convention in Paris, and died there of a fever on 10 January 1794.

Forster, WILLIAM (1818-1882), was born at Madras in 1818 and brought to Australia in 1829 by his father, Dr. T. Forster of the 50th regiment, who settled at Brush Farm near Parramatta. He was educated by W. T. Cape, and became a squatter, but in his leisure hours composed political satires (chiefly directed against Sir G. Gipps) for the squatters' organ, the *Atlas*; this newspaper disappearing at the end of 1848, Forster was from 1850 onwards a contributor to Henry Parkes's *Empire*. When New South Wales obtained responsible government, Forster was sent to the first assembly by the Murray electorate, and so commenced an uninterrupted parliamentary career of 20 years, during which he represented the Murray (1856-9), Queanbeyan (1859-60), East Sydney (1861-4), the Hastings (1864-9), Queanbeyan again (1869-72), the Illawarra (1872-4) and the Murrumbidgee (1875-6). During these years he was four times in office—as premier from 27 October 1859 to 8 March 1860 (he was defeated on a proposal to make the legislative council elective), as colonial secretary in the first Martin ministry (October 1863 to February 1865), as secretary for lands in the Robertson-Cowper ministry (October 1868 to April 1870), and as colonial treasurer in a later Robertson ministry (February 1875 to February 1876). On 4 February 1876 he was made agent-general, and lived in England until the end of 1879. Returning to Sydney a year later, he found he had been elected during his absence for Gundagai; this seat he held till his death on 30 October 1882.

Forster's political career, though continuous, was erratic, as is evident from his numerous migrations among the constituencies. He was not, in fact, a great parliamentarian; he lacked eloquence—which in the sixties was much valued—and was perhaps over-equipped with powers of caustic criticism such as makes sincere partisanship impossible and becomes occasionally awkward for one's own side. But both inside and outside parliament he was an influence for good, maintaining and enforcing on his friends a high standard both of political behaviour and of literary excellence, as it was in those days understood. His pungent criticism of insincere work, written or spoken, was in its day a valuable corrective of the extravagances of his would-be leaders. In the sphere of pure literature he did little; his only published works of this kind are *The Weirwolf, A Tragedy* and *The Brothers, A Drama*, written in New South Wales but published in London in 1876-7 while he was agent-general.

Fortesque, a small fish (*Centropogon australis*) rarely reaching a length of six inches, which is well known to fishermen on account of its power of inflicting painful wounds. On

each side of the snout grooved spines project backward; these are erectile, and are provided with glands secreting a venom which is used effectively by the fish if it be grasped incautiously, and causes an extremely irritating wound that not infrequently becomes inflamed. The fortesque is very common in New South Wales, and is often found in considerable numbers in prawn-nets which have been dragged over flats covered with sea-grass. Other closely allied species occur in Queensland, and the southern coasts of Australia and Tasmania are inhabited by the Soldier or Cobbler (*Gymnapistes marmoratus*) a species with the same armament as the fortesque. All these are strikingly marked with dark brown blotches upon a light ground, which doubtless serve as warning markings, the fishes being free to flaunt themselves in the presence of enemies by virtue of their venomous qualities.

Foster, J. F. See FITZGERALD, J. F. V.

Foveaux, JOSEPH (1765-1846) was born in England in 1765. Nothing is known of his life until on 5 June 1789 he joined the New South Wales Corps (lieutenant, 1789; captain, 1792; major, 1796; lieutenant-colonel, 1802; major-general, 1814; lieutenant-general, 1830). In the corps he ranked as major as long as it was in New South Wales; his promotions of 1802 and later relate to army rank. His career in New South Wales from 1792 to 1801 was undistinguished, and his attention was devoted chiefly to farming his grants of land on Port Jackson and at Petersham and Toongabbie; in 1800 he had 31 cattle and 1200 sheep. In that year King, finding that Norfolk Island was being administered by captains of the corps changed every year, decided to station Foveaux on the island as a permanent lieutenant-governor, and the appointment was made out on 26 June, though the formal commission was not signed until 9 June 1801. Almost immediately after arrival he discovered and suppressed an incipient rebellion among the convicts, and was commended by the British authorities for his promptitude and vigour. He left the island on account of ill-health in 1803, and was soon afterwards relieved of the appointment, as the establishment there was to be much reduced. On 9 September 1804 he went to England on leave of absence, and while there drew up a plan for the evacuation of the island which the colonial office adopted.

On July 1808 he returned to Sydney, on his way to take up again the administration of the island with a view to its final evacuation. But he found that Bligh had at the beginning of that year been deposed by Johnston, and that an appeal had already been made to the British ministry. In these circumstances he decided not to reinstate Bligh, but to take over the government himself—being senior to Johnston—and carry on until news came from England. In so doing he managed to incur the hostility of both parties, for Bligh attacked him for his 'great intimacy' with Macarthur, while Macarthur called him 'that unprincipled man Mr. Foveaux.' Against these opinions may be set Macquarie's judgment that 'he could not with safety have adopted a different line of conduct from that he pursued.' Foveaux's assumption of the government was nominally terminated by the arrival from Tasmania of Paterson, who on 1 January 1809 took charge of affairs as lieutenant-governor; but Paterson was old and ill, and the practical work of administration was Foveaux's until Macquarie arrived at the end of the year. Macquarie at once approved of Foveaux's actions, praised his conduct of public affairs, and recommended him as a successor to Collins in the lieutenant-governorship of Tasmania. 'I have' he wrote, 'never yet met with any Officer . . . . that is more eminently qualified for forming and conducting to maturity and perfection any Infant Colony committed to his charge.' Foveaux's public works policy was undoubtedly praiseworthy: he found the Sydney streets almost impassable, the bridges dangerous and neglected, and the barracks, stores, and other public buildings much decayed, and in 18 months had greatly improved all roads and bridges and erected new buildings of sound quality, besides completely reforming the police force and reintroducing into the public service the virtues of industry, regularity, and economy.

On 17 March 1810 Foveaux sailed for England, to find on arrival there that he was liable to be tried by court martial for assenting to Bligh's deposition and imprisonment. On this account Macquarie's recommendation with regard to Tasmania was set aside; but in 1811 he was taken back into active service in the army and given a regiment of light infantry. His later career was undistinguished, and he died in London on 20 March 1846.

Fox Shark. See THRESHER SHARK.

Foxton, JUSTIN FOX GREENLAW (1849-1916), born near Melbourne on 24 September 1849 and educated at the Melbourne grammar school, was taken to Brisbane in 1864, trained for the law, and admitted a solicitor in 1871. In 1883 he entered parliament as member for Carnarvon, a seat which he retained until 1904. In May 1896 he was taken into the Nelson ministry as secretary for lands, retained that position in the Byrnes ministry (1898), became home secretary under Dickson (1898-9), and held that position under Philp (1899-1903), thus being continuously (except during the week-long Dawson ministry of 1899) in office for over seven years under four premiers. During this time he was responsible for much important legislation. As minister for lands he carried the crown lands act of 1897, which created a land court and a land appeal court, arranged for 21-year pastoral leases, and invented the 'prickly-pear' leasehold tenure. He had in the previous year carried a factories and shops act which severely limited child labour; but his chief achievement in this direction was his factories and shops act of 1900, the first really modern industrial legislation ever passed in Queensland. In 1887 he represented Queensland on the federal council. In 1906 he entered the federal parliament as member for Brisbane; in the 'fusion' ministry of 1909-10 he was honorary minister, and as such attended the important London conference of July 1909 which devised the 'unit' system of naval defence in Eastern waters. Defeated at the elections of 1910, he retired from politics, and died at Brisbane on 23 June 1916.

His hobby was soldiering. In 1869 he was commissioned lieutenant in the local field artillery, rose to be captain in 1884 and major (commanding the Brisbane field battery) in 1888, and after federation became commandant of the Queensland field force. (C.M.G., 1903.)

Francis, JAMES GOODALL (1819-1884), born in London and brought to Tasmania in

1834, entered commercial life as a clerk in the firm of Boys and Pointer, which in 1847 passed into his hands and those of a partner. In 1853, when Melbourne was growing rapidly on account of the gold discoveries, the firm opened a branch there and Francis became its manager; he soon established his position in the commercial world, becoming vice-president of the local chamber of commerce in 1856 and president in 1857. In October 1859 he was elected to the assembly by Richmond, and in November joined the Nicholson ministry as commissioner of public works; within a year, however, he left Nicholson and remained out of office until the advent of the McCulloch ministry (27 June 1863), in which he was commissioner of trade and customs. In McCulloch's third ministry (1870-1) he was treasurer. On 10 June 1872 he himself became premier of a coalition ministry that lasted just over two years, and carried against a good deal of denominational opposition an education act, based mainly on the report of Higinbotham's commission of 1866, which settled the colony's educational policy for more than 30 years. In 1874 a bill of his for settling disagreements between the two houses by joint sittings being coldly received, he retired from the ministry in favour of G. B. Kerferd. Returning to politics in 1878 as member for Warrnambool, he was honorary minister under James Service in 1880; but his failing health could not stand the strain, he abandoned politics in 1882, and died at Queenscliff on 25 January 1884.

Franklin, Sir John (1786-1837), born at Spilsby in Lincolnshire on 16 April 1786, and educated for the church, preferred a career in the navy, which he entered on 1 October 1800 (midshipman, 1800; lieutenant, 1808; commander, 1821; post-captain, 1822), joining H.M.S. *Polyphemus* and in her taking part in the battle of Copenhagen (1 April 1801). Immediately afterwards he was appointed to H.M.S. *Investigator*, which under command of his cousin, Matthew Flinders, was about to explore the coast of Australia. An account of this voyage is given under Exploration by Sea. Franklin followed Flinders into H.M.S. *Porpoise*, but after its wreck and the subsequent rescue accompanied Lieutenant Fowler to China in the *Eolia*; thence he took passage for England in the East India Company's ship *Earl Camden* under Sir Nathaniel Dance, who with a fleet of 16 merchantmen on 15 February 1804 defeated the French squadron under Admiral Linois, Franklin being Dance's signal-midshipman during the fight. Upon arrival in England he was appointed to H.M.S. *Bellerophon* and on 21 October 1805 was her signal-midshipman at Trafalgar. After a period of varied service he was present at the blockade of Flushing in 1814, and at the attack on New Orleans. In 1818 he commanded the brig *Trent* in Buchan's Arctic expedition (25 April to 22 October), and in 1819-22 commanded an expedition which traversed the northern latitudes of North America to determine its coast-line. On his return the Royal Society elected him a fellow and chose him to serve on its council. In 1825-7 he continued his survey of the North American coast; this expedition brought him a knighthood, the Oxford degree of D.C.L., and the gold medal of the Geographical Society of Paris.

In 1830-3 he commanded the *Rainbow* frigate, cruising usually on the coast of Greece; then, after a short rest, he was in 1836 appointed lieutenant-governor of Tasmania and reached Hobart on 6 January 1837, taking with him as private secretary Alexander Maconochie (q.v.). His appointment (warmly supported by William IV) was probably due (*a*) to the desire to reward his valuable services with a colonial governorship—a common practice at that time in military cases, all the governors of New South Wales from Brisbane to Fitzroy being officers of Wellington's armies—(*b*) to the desire to replace Arthur, a great but autocratic administrator, by a man more in consonance with the humanitarian and politically liberal ideas of the Grey-Durham-Buller school of politicians. Highly cultured, exceptionally humane, yet inured to naval discipline and a proved leader of men, he was exactly suited to his post; but the post was less well suited to him. He had looked forward to it as a period of easy and dignified repose after much toil; he found it a succession of struggles against the brutality of the convict system and the vested interests of Arthur's favourites and relatives. His own chief interests were the amelioration of the convicts' conditions of life, and the gradual improvement of social life in general by the better organization of education and adult studies. He enlisted the aid of Dr. Arnold of Rugby, who framed a scheme for a local college; the legislative council sanctioned the proposal, and the foundation stone was laid at New Norfolk, but the college was never built. For the advancement of science he established the Tasmanian Society, which in 1842-6-9 published three valuable volumes dealing with Australian science. But in the early forties the British control of colonial affairs passed from the hands of the Durham school into those of Lord Stanley, and humanitarianism was at a discount; Montagu, Arthur's nephew and Franklin's official secretary, whom he had dismissed for over-independence in dealings with matters that were the governor's prerogative, was backed by Stanley, and Franklin was recalled with a certain insolence. His successor, John Eardley-Wilmot, reached Hobart four days before Franklin was informed that he was to be recalled

Franklin's term of office ended on 21 August 1843, but he did not leave Hobart till November, visited New Zealand, and sailed from Port Phillip for England on 12 January 1844. Within nine months of his arrival he was again employed in Arctic exploration. The *Erebus* and *Terror* had just returned from the Antarctic, and it was decided to send them to discover the long-desired and apparently mythical North-west Passage. Franklin claimed the command, as the senior officer with Arctic experience, and on 18 May 1845 sailed for Greenland. On 26 July his ships were sighted off the entrance to Lancaster Sound. It was 14 years before anything definite was known of him or them. The expedition was provisioned for three years, and until that period was over no active steps were taken to relieve him; but between 1848 and 1857 no less than 38 relief expeditions were despatched from England or the United States, and, though only three found any traces of Franklin, and only the last (F. L. McClintock's in 1857-9) ascertained his fate, the results in opening up the Arctic regions were unsurpassed in the history of discovery. It seems that lack of provisions—great stacks of preserved-meat tins with putrid contents were found on Beechey Island—and exceptionally long and severe winters, that blocked with ice normally open sea-passages, proved fatal to the expedition; Franklin died on 11 June 1847, the ships were de-

sorted on 22 April 1848, and the refugees perished to a man in attempting to cross the frozen wildernesses of the Fish River estuary.

For the world at large Franklin's work was mainly connected with Arctic exploration. For Australians he is especially the man who tried to make convictism compatible with humanity; and his failure—or, rather the decision of the British government that he had failed—was the final proof that the two were incompatible, and to the essential factor in procuring the abolition of the system. (Kt. Bach., 1829; K.C.H., 1836.)

His second wife, JANE FRANKLIN (1792-1875), was married to him on 5 November 1828, and accompanied him both to Greece and to Tasmania. While there she travelled extensively on the Australian mainland as well as in the island, in 1839 crossing from Melbourne to Sydney via Yass and the Illawarra, in 1841 from Adelaide to the mouth of the Murray in Encounter Bay. She devoted herself particularly to the welfare of female convicts and of the poorer settlers' wives, and did her best to establish near Hobart a high school for girls. Montagu's attacks on Franklin were barbed with insinuation that Lady Franklin's too great influence over him disposed him to undue leniency, and certain local newspapers openly repeated the charge—which seems to have been wholly unfounded; her husband, at any rate, repudiated it with scorn. In 1841 she persuaded Gawler, then governor of South Australia, to provide at Port Lincoln a site for a monument to Matthew Flinders, and later in the year Franklin at his own expense erected a commemorative obelisk there. Lady Franklin is said to have initiated an attempt to make Tasmania a second Ireland by offering a shilling a head for snakes. For a time snakes' heads came in freely, and the payment was soon discontinued. Her later years were spent at first in fitting out expeditions to search for the *Erebus* and *Terror*, then in almost constant travel through and beyond Europe. She died in London on 18 July 1875.

Freemasonry. The first reference to Freemasonry in Australia is contained in a document dated 17 September 1802 which purports to admit Anthony Fenn Kemp 'into the grade of Ancient Masonry.' It is signed by Jacques St. Cricq, 'sovereign prince of Rose Croix,' George Bridges Bellasis, and Jerome Bellefin—Bellasis being artillery officer in the colony and the other two officers in the *Naturaliste*, a ship of Baudin's expedition. This document, however, concerns a continental form of masonry, and the first mention of British Freemasonry relates to the attempt, early in 1803, of Sir Henry Browne Hayes (q.v.)—in conjunction with officers of H.M.Ss. *Glatton* and *Buffalo* and several residents in Sydney—to establish a Masonic lodge and initiate new members. Governor King, however, prohibited the meeting and threatened Hayes with transportation to Norfolk Island. The meeting was nevertheless held early in May; but the police raided it, and Hayes was sentenced to deportation to Tasmania—though he somehow or other evaded this penalty. This meeting is regarded by Australian Freemasons rather as an interesting event than as a regularly-constituted Masonic gathering; no records of it are extant, and its objects are not known. One principle of the Craft is compliance with the law, and clandestine meetings are Masonically irregular.

In February 1814 the 46th regiment came to Sydney; its lodge had a regimental warrant from the Grand Lodge of Ireland, and was named 'The Lodge of Social and Military Virtues.' The lodge of the 48th regiment, which arrived in 1817, also held a warrant (No. 218) from the Grand Lodge of Ireland. The lodge of the 46th, on return to Great Britain, recommended the Irish Grand Lodge to grant a permanent charter to the Freemasons of the new country; this was done by warrant No. 260, naming the 'Australian Social Lodge' as the first colonial lodge. This lodge was established on 12 August 1820, which is the recognized date of the foundation of Freemasonry in Australia. The lodge has twice changed its name; it was first 'The Australian Social Mother Lodge,' but shortly after its centenary in 1920 assumed the name 'The Lodge of Antiquity.' The next lodge, formed by dispensation granted by lodge No. 260, was called 'Leinster Marine Lodge of Australia;' the dispensation was confirmed by warrant No. 266 from the Grand Lodge of Ireland, dated 12 February 1824. The first lodge under the English Constitution was the 'Lodge of Australia' No. 820, opened in 1838, which is now No. 3 on the register of the United Grand Lodge of New South Wales. The first Scottish lodge was 'Sydney St. Andrew' No. 358 (now No. 7). Then followed a quick succession of other lodges, which gave Freemasonry such a firm standing in the colony that the Grand Lodge of England was enabled to institute a Provincial Grand Lodge in 1839, followed by the Scottish in 1856, and by the Irish in 1858.

In the eighties there became manifest a marked desire for a properly constituted and duly recognized Grand Lodge of New South Wales. The position was acute, because 13 Irish lodges had in 1878 formed a so-called 'Grand Lodge of New South Wales,' which was never officially recognized by the Grand Lodges of Great Britain. When in 1885 Lord Carrington became governor of the colony, he was empowered by the Grand Master of England (the then Prince of Wales) to bring about a Masonic reconciliation; in this objective he was materially assisted by the arrival in 1888 of the Earl of Carnarvon, pro-Grand Master of England. After several conferences and an active canvass among the Lodges, a committee of five prominent brethren from each constitution was appointed to draw up a basis of union. 'The United Grand Lodge of New South Wales' was formally inaugurated in the Great Hall of the university of Sydney on 16 August 1888, under the auspices of the Grand Lodge of England, and fraternal recognition by all Grand Lodges of the world followed in due course. On 18 September Lord Carrington was installed as first Grand Master by Sir Samuel Way, Grand Master of South Australia, in the presence of 4000 Freemasons. The Grand Lodge thus started represented about 5600 brethren attached to 176 lodges.

In October 1923 the 500th lodge was dedicated under the name of 'Lodge Literature,' being composed of brethren connected with the press and with authorship. At that date the membership of the order in New South Wales was 52,000; its assets amounted to £213,000; and the probable value of Masonic real estate in New South Wales was at least £500,000. In the same year the William Thompson Masonic Schools for Orphans were opened.

Other Masonic activities under the United Grand Lodge of New South Wales are the Freemasons' Benevolent Institution—a society of voluntary subscribers, which arranges for

permanent pensions to the aged, the widows, and the permanently incapacitated—the New South Wales Masonic Club, and the Freemasons' Orphan Society. There is also a Freemasons' scholarship at the university of £50 per annum for three years for the sons of Freemasons of five years' membership.

Royal Arch Freemasonry was first practised in New South Wales by virtue of a warrent held by the Australian Social Mother Lodge. This warrant was returned to the Grand Lodge of Ireland in 1877, but the Lodge is still in possession of the original seal of the Chapter. There is evidence in the minute-book that the Royal Arch degree was conferred by this lodge as early as 4 June 1827; the Mark degree was conferred even earlier, on 8 November 1820. Leinster Marine (Irish) Chapter was established in 1848, Zetland (English) Chapter in 1855, and Burrangong (Scottish) Chapter in 1863. The Supreme Grand Chapter of New South Wales was established by the English Chapters in 1889.

The Mark Master Mason's degree is worked by Scottish and Irish Chapters, but not by the New South Wales Chapters, the latter leaving that degree to the Grand Mark Lodge of New South Wales, established in 1889.

Other branches of Freemasonry in New South Wales are the Ancient and Accepted Rite (33°) worked under the English and Scottish jurisdictions; the Knights Templar (English and Scottish systems) and the Knights of Constantine (Scottish). Appended to the New South Wales Mark system are the Royal Ark Mariners, and to the Scottish Royal Arch system the Ark and Red Cross and Cryptic degrees.

In *Tasmania* the first lodge—known as 'The Royal Fusileers' Lodge No. 33—was started by the 21st regiment, which held a charter from the Grand Lodge of Ireland, dated 1763. Another lodge was attached to the 51st regiment, and lodge meetings were held in the barracks at Hobart. From these in 1828 grew up a civilian lodge known as 'The Tasmanian' Lodge No. 31, under charter from the Grand Lodge of Ireland. Between 1828 and 1833 another civilian lodge was established, called 'Union' Lodge No. 326, and in 1834 was founded the 'Tasmanian Operative' Lodge (No. 345 under the Irish constitution). The removal of the 21st regiment caused the introduction of another civilian lodge, as the Master and senior warden of the regimental lodge settled in Tasmania and applied to the Grand Lodge of Ireland for a stationary warrant: this was granted in 1842, and the old title and number was allowed to be retained. On 26 October 1842 the first step for establishing a lodge in Launceston was taken when the lodge named 'St. John's' was established under a dispensation from the Tasmanian Operative Lodge. This new lodge received a warrant from the Grand Lodge of England and was No. 346, I. C., although it had previously applied to work under the military lodge No. 404, E. C. The lodge was opened on 19 January 1843, and in the same year the Masonic Benevolent Fund was started in Hobart. In 1844 at Hobart, the brethren of the Tasmanian Operative Lodge, mentioned above, applied for a warrant under the English constitution and called the lodge 'The Tasmanian Union;' it at first worked under dispensation from the Deputy Grand Provincial Master of Australasia at Sydney, and afterwards received a warrant bearing the number 781. This was the first introduction of English Freemasonry into Tasmania. On 7 September 1852 the 'Lodge of Hope' was erected. In 1855 the first Royal Arch Lodge was formed, and in November of that year three lodges obtained a Provincial Grand Lodge under the English constitution; but in 1860 this ceased to exist. During 1884 a petition from the various Irish lodges for a Provincial Grand Lodge was granted, and on 14 October the first Provincial Grand Master was installed. In 1885 the Scottish Masons made a move for a District Grand Lodge, and this was effected in August. In January 1888 all the lodges discussed the desirability of establishing a Tasmanian Grand Lodge; on 6 March 1890 decisive steps were taken, and on 26 June the Grand Lodge became an accomplished fact, with 22 lodges within its jurisdiction.

In *South Australia* Freemasonry dates from 22 October 1834, when the South Australian 'Lodge of Friendship' (No. 613 under the English constitution) was formally consecrated at No. 7 John-street, Adelphi, London; the Lodge was to meet monthly in the intended settlement of the colony of South Australia. A second meeting was held at the same place on 2 March 1835, but the next meeting was held on 11 August 1838 at the assembly rooms in Black's hotel in Franklin-street, Adelaide. In August 1841 Governor Grey of No. 83 Military Lodge became a member, and on 31 January 1844 E. Solomon offered the lodge a quarter of an acre of land for Masonic purposes and 10,000 bricks with which to build a lodge-room. In 1838 the lodge met at the Turf hotel in Weymouth-street, and in 1843 in Lambeth's auction room in Hindley-street. On 1 February 1844 the Adelaide St. John's Lodge was solemnly consecrated by the Lodge of Friendship; on 6 February the Lodge of Harmony was formed under a dispensation granted by the Lodge of Friendship under the English constitution, and on the 9th was duly consecrated. On 20 November the Lodge of Friendship memorialized the Grand Master of England for permission to form a provincial grand lodge in South Australia, and in January 1848 the Provincial Grand Lodge of South Australia was constituted—it was afterwards called the District Grand Lodge. On 16 October 1861 a Royal Arch Chapter was formed in connection with the Lodge of Harmony. In 1866, upon a memorial issued from South Australia, the powers of District Grand Lodges were greatly enlarged. Eventually the Grand Lodge of South Australia was established, on 16 and 17 April 1884 the charters of the lodges under the English, Irish, and Scottish constitutions were surrendered to this Grand Lodge, and on the 17th the inauguration ceremony was performed. Owing to a conflict of opinion whether the Grand Lodge was properly constituted, an independent charter was applied for and received from the Mother Grand Lodge of the United Kingdom. On 18 July 1889 Chief Justice Way resigned his Masonic office as Grand Master of the Grand Lodge of South Australia, and the United Grand Lodge was established. On 10 October the Earl of Kintore, then governor of the colony, was elected Grand Master, and on the 30th was installed by Lord Carrington, the Grand Master of the United Grand Lodge of New South Wales, assisted by Sir William John Clarke, Grand Master of the United Lodge of Victoria.

In *Victoria* on 23 December 1839 21 Freemasons petitioned the Grand Lodge of England to be recognized as 'Lodge of Australia Felix;'

the lodge was opened on 25 March 1840. The first lodge under the Scottish constitution was 'Australasian Kilwinning' No. 408, S. C. (now No. 2 V. C.). The first Irish Lodge was 'Australia Felix of Hiram' No. 349 (now No. 4 V. C.). The Scottish Provincial Grand Lodge was formed in 1847, the Irish Provincial Grand Lodge in 1854, and the English Provincial Grand Lodge in 1857. In 1882 Sir W. J. Clarke accepted the combined offices of Provincial Grand Master under the English, Scottish and Irish constitutions—a unique thing in Freemasonry. His object was, of course, an attempt at union, which did not immediately eventuate. In 1883 a Grand Lodge of Victoria was opened, but the Grand Lodges of the mother-country did not grant it recognition. In 1888, with the help of the Earl of Carnarvon, pro-Grand Master of England, a United Grand Lodge of Victoria was formed. All lodges in Victoria are under its jurisdiction, with the exception of Lodge Combermere No. 752, E. C. The United Grand Lodge has a Temple for administrative purposes and lodge meetings in Collins-street, Melbourne; the Victorian Masonic Club is at 64 Swanston-street; houses are provided for elderly brethren under the group system at South Yarra. Other Masonic systems in Victoria are the Grand Chapter of Royal Arch Masons, the Grand Mark Lodge, the Rosicrucian Order, English and Scottish Knights Templar and the Ancient Rite.

In *Queensland* Freemasonry was first established just after the separation of the colony from New South Wales, the 'North Australia' Lodge No. 1098 being founded in Brisbane under the English constitution in December 1859. The 'Prince of Wales' Lodge No. 1210, the 'Queensland' Lodge No. 1223 at Ipswich, and the 'Leichhardt' Lodge at Rockhampton, were founded shortly afterwards; the 'St. Patrick' Lodge No. 270 under the Grand Lodge of Ireland followed in 1863, and the 'St. Andrew' Lodge No. 435 under the Grand Lodge of Scotland in 1864. A District Grand Lodge under the English constitution was founded in 1862, and one under the Irish constitution in 1866: the latter included five lodges, a Mark Master lodge, and a Royal Arch chapter. A Provincial Grand Lodge established under the Scottish constitution in the same year had under it three lodges. In 1887 and 1897 efforts were unavailingly made to establish a sovereign Grand Lodge of Queensland, but on 20 August 1903 a deputation of Past Masters brought the matter before the Provincial Grand Master of the Irish constitution, and early in October a cable message from the Grand Lodge of Ireland intimated that it would approve of the proposed Grand Lodge for Queensland if it were 'regularly formed.' On 19 December it was resolved to form such a Grand Lodge, and after some friction—caused, apparently, by the irregular issue of circulars to lodges under the English constitution—a convention of delegates on 25 April 1904 declared the formation of the Grand Lodge of Queensland, with the constitution of New South Wales as a basis. On 7 September the Grand Lodge of England announced that it could not recognize the newly made Grand Lodge as having any jurisdiction in Queensland. However, after some correspondence the United Grand Lodge of New South Wales recognized the new body on 14 September, and on 29 October the installation of the Grand Master was performed by the Grand Master of New South Wales. The name of the new body was 'The Grand Lodge of Antient Free and Accepted Masons of Queensland,' and under it were 44 lodges, a board of general purposes, a board of benevolence, and a widows', orphans', and aged masons' institution. The District Grand Lodge under the English constitution governed 80 lodges and a district board of general purposes; there was also a District Grand Lodge of Mark Master Masons of England and Wales with about 20 Mark lodges. Under the Scottish constitution there were nearly 50 lodges in the southern jurisdiction and 20 in the northern. The District Grand Royal Arch Chapter of Queensland had fully 20 chapters in full working order.

In 1920 there was started a movement to bring about unity between the three constitutions, and as a beginning 85 lodges under the English constitution and 101 under the Scottish established the Queensland Grand Lodge. On 27 April 1921 the lodges under this Grand Lodge and the Grand Lodge of Queensland (281 in all) joined in forming the United Grand Lodge of Queensland, which has now (1924) 319 lodges on its roll. There are still three lodges holding under the Grand Lodge of England, and one under the Grand Lodge of Scotland.

Western Australia. It was not until 1842 that the first lodge was opened in this colony; this was the 'St. John' Lodge No. 712, working under the Grand Lodge of England. In 1845 another English lodge, the 'Unity,' was opened, but in 1879 the two lodges amalgamated under the first lodge's title, and this lodge is now No. 1 of the Western Australian constitution. Scottish Freemasonry was as active in opening lodges as was the English constitution. The District Grand Lodge (E.C.) was formed in 1877. The Grand Lodge of Ireland had but two lodges in Western Australia at that time. In the nineties, after many preliminary attempts, the founding of a Grand Lodge for Western Australia was seriously taken in hand, especially in view of a previous unauthorized attempt to form a Grand Lodge that would not have had even three lodges to govern. The leaders of the real movement to found a Grand Lodge were so successful in their operations that on 11 October 1899 the Grand Lodge of Western Australia was declared open; Sir Gerard Smith, then governor, was elected Grand Master, and was installed in February 1900, with jurisdiction over 33 lodges for a beginning.

The unwontedly close association, in the trenches and during most operations of the late war, of Australians who might otherwise have never come into contact with each other, resulted in a great accession of members to Freemasonry. In Australia, therefore, the Craft is both numerically strong and financially stable, with about 100,000 subscribing members and a capital (in real estate and reserve funds owned by the six Grand Lodges) of over £1,000,000. British Masonic law is closely followed, with occasional adaptation to Australian conditions, and the study of Masonic traditions, history, and evidences is carried on both by private students and in research lodges established for that purpose in each Australian metropolis. Fremantle. See PERTH.

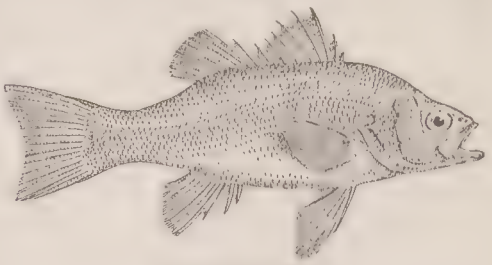
Fremantle, SIR CHARLES HOWE (1800-1869), born on 1 June 1800, was the second son of Admiral Sir T. F. Fremantle, a com-

panion of Nelson in most of his great exploits. He entered the navy in 1812 (lieutenant, 1819; commander, 1822; captain, 1826; rear-admiral, 1864), and saw active service as a midshipman at the blockade of New Orleans in 1814. In 1828, when in command of H.M.S. *Challenger*, he was ordered to proceed to the Swan River to take formal possession for the British crown of 'all that part of New Holland which is not included in the territory of New South Wales.' He arrived on 25 April 1829, and on 2 May hoisted the Union Jack on the south head of the river, where Fremantle now stands. Captain Stirling and other officials, together with the first band of settlers, reached Swan River on 1 June, and the *Challenger* left Swan River on 28 August for India. Fremantle served with distinction during the Crimean war, became commander-in-chief at Devonport, and died in 1869. (K.C.B., 1857; G.C.B., 1867.)

French, Sir George Arthur, born at Roscommon in Ireland on 19 June 1841 and educated at the royal military college, Sandhurst, and the royal military academy, Woolwich, joined the royal artillery in 1860, went to Canada as adjutant R.A. in 1862, was commissioner of the north-west mounted police from 1873 to 1876, and in that capacity took part in the Red River expedition of 1874. After a period of service (1878-83) at Devonport, he was in 1883 made commandant of the Queensland military forces, retiring in 1891 with a reputation that brought him in 1896 the command of the military forces of New South Wales. His strenuous and successful training of these troops was largely responsible for the value attached to the services of New South Wales contingents in the South African War. He retired from the army in 1902, and has since lived privately in England. (C.M.G., 1877; K.C.M.G., 1902.)

French, Sir John Russell (1847-1921), born in India in 1847, was brought by his parents to New South Wales in 1858. His father settled at Kameruka on the south coast, but died almost at once, and the boy in 1863 entered the service of the Bank of New South Wales; he passed through all grades of service, becoming an inspector in 1872, chief inspector in 1891, and general manager in 1894. Taught by the banking crisis of 1893 (which had been handled by his immediate predecessor, but with the advantage of his cool advice), he at once joined T. A. Dibbs (see Dibbs, Sir G. R.) in a campaign to obtain uniform banking legislation throughout Australia. Holding aloof from politics as such, he became the adviser of State and Federal treasurers, and made his bank the most influential in Australia, always insisting that steady rates of interest were best for business, and more advantageous for the banks than the occasional high profits obtainable when rates fluctuated. During the war his help was invaluable to ministries in search of a sound financial policy, as well as to charitable institutions and to the administators of various funds that were established for war-purposes; and almost his last moments were spent in devising remedies for the tangled exchange situation of 1920-1. He died at Sydney on 30 June 1921. (K.B.E., 1918.)

Freshwater Perch (*Percalates colonorum*), inhabits the coastal streams of south-eastern Australia between Moreton Bay and Spencer Gulf, and also occurs in Tasmania. Though a freshwater fish, it often descends to saltwater estuaries, where it is largely captured by net-fishermen and is known as 'estuary perch.' It is very variable in form, a fact



Freshwater Perch.

which has led to its subdivision by some writers into several species. It provides excellent sport for rod-fishermen, and occasionally attains a length of 20 inches. A.R.McC.

Freycinet, Louis de. See Exploration, French.

Friar-birds, perching birds belonging to the genera *Tropidorhynchus*, *Philemon*, and *Entomyza*, members of the family of honey-eaters (Meliphagidae), q.v. The two former genera occur in eastern and northern Australia, New Guinea, and the Papuan islands; the last is confined to eastern and northern Australia.

Leatherhead.

These birds, which are among the largest members of the honey-eater family, are characterized by moderately long, curved bills and the absence of feathers from part or the whole of the head; hence some of them are often called leatherheads.

The common Friar-bird or Leatherhead (*Tro-*

pidorhynchus corniculatus) of eastern Australia has the whole of the head and neck bare, the naked skin being black. A small hump or protuberance rises from the base of the upper mandible of the beak. In the Helmeted Friar-bird (*T. buceroides*), of northern Queensland and the Northern Territory, the hump is very much larger, as implied by its name. The Silver-crowned Friar-bird (*T. argenticeps*) of northern Australia has some silvery feathers on the top of the otherwise naked head. The Yellow-throated Friar-bird or Little Leatherhead (*Philemon citreogularis*), of northern and eastern Australia, has no hump on the bill; only the sides of the head are bare, the naked skin being dark bluish-grey. The frier-birds are dull-coloured, brown above and whitish below, with pointed, silvery-white feathers on the breast. They are very noisy, and utter most curious chuckling notes and gurgling sounds, that give the effect of carrying on a conversation.

The two species of *Entomyza* are nearly related to the friar-birds, but differ decidedly in colour, being rich yellowish-green above and white beneath, with black patches on the head and breast. The sides of the head are naked, and the skin a rich greenish-blue. The Blue-faced Honey-eater (*E. cyanotis*) is fairly common in south-eastern Australia; the White-quilled Honey-eater (*E. albipennis*) occurs in northern Queensland and the Northern Territory.

W.B.A.

Friends, Society of. This religious body, which had its rise in England about 1650, and is closely associated with the name of its first leader, George Fox, has been represented in Australia from early days. For a time, owing to its small and widely scattered membership, it lacked organization; and its history illustrates the difficulty that besets all small communions in maintaining their individuality. Where but few members live within easy reach of one another, the question often arises whether in their own best interests—and especially in the interests of their children—it is more desirable to keep up a limited separate congregational life, or to unite with neighbouring churches. Where the latter course is chosen, the energies of the individual become merged in those of the gathering with which he has associated himself, and whatever was distinctive in his earlier belief may be gradually lost.

As an organized body, 'Friends' in Australia date from the missionary labours of James Backhouse (q.v.) who in 1831 came to Australia under a strong sense of duty, officially accredited by the Society of Friends in England. His credentials were wide in their scope; 'to visit in the love of the Gospel the inhabitants of the British Colonies and Settlements in New Holland, Van Diemen's Land and South Africa.' He also brought introductions to officials in authority, for he was a well-known and many-sided man of science, apart from his special call to religious service. Arriving in Hobart early in 1832, Backhouse drew together the few Friends he could find, and united them to form a regular congregation. This as time went on grew in numbers and branched out, other meetings being formed up and down the country. Backhouse laboured throughout Australia for six years. Before he returned to England in 1837, Sydney and Melbourne had established Meetings, and about the same time a similar advance was made in Adelaide and Brisbane, which became in due course centres for other congregations. Thenceforward, with some fluctuations, the progress of the Society of Friends has been steady, if slow. They are still a small body, but not without influence; and the drawing together of the different States, politically and through the development of facilities of intercourse, has helped Friends greatly and increased their solidarity. Their adherents in full membership do not exceed 1000 in the Commonwealth of Australia, but they are represented from time to time in the legislatures and other responsible public bodies.

Church government has as its basis the Monthly Meetings in Tasmania (held in Hobart), Victoria (Melbourne), New South Wales (Sydney), the Two Months' Meeting of South Australia (held alternately at Adelaide and Eden Hills), and the corresponding Meeting for Queensland (held in rotation at Brisbane, Toowoomba, and Rockhampton). Representatives from these constitute the General Meeting held annually at Sydney, Melbourne, Hobart, and Adelaide in succession, which is the authorized mouthpiece of the Society throughout Australia. It is, however, itself a constituent part of the London Yearly Meeting, the recognized synod and focus for all English Friends.

About 35 years ago a Friends' high school was established in Hobart, to subserve the needs of all the mainland States; pupils have been sent to it from Torres Straits in the north, Perth in the west, and New Zealand in the east, and its roll of pupils is now (1925) about 250. It accepts all who desire a guarded education under Quaker influence, but may in other respects be considered unsectarian.

It would not be appropriate here to enter into questions of doctrinal belief, or to dwell on what Friends have stood for, as citizens, in the national life. Their record is public property. During the recent war some members came into public notice as 'conscientious objectors,' refusing military training and service, and suffering imprisonment for so doing both in Australia and New Zealand. But though they refused to bear arms, the Quaker young men of Australia gave themselves freely for non-combatant service at the front in ambulance corps and similar work, as voluntary workers, accepting no remuneration. The Friends' War Victims Relief Committee, too, from its central London offices sent young men and women out in hundreds to render help of every kind wherever the need was greatest. Amongst these were young Friends from Australia and New Zealand, who took leading positions in the organized relief of the refugees who swarmed into Holland; in the war-wasted provinces of France (where the government entrusted a large district to their care to be rehabilitated); in Austria and Poland and the wastes of Russia, and even in Serbia. After the armistice their efforts were largely concentrated upon famine relief. In Russia they were for a time the only organization allowed any facilities by the Soviet government, and their work was on a large scale.

W.B.

Frigate-birds, large marine birds, mostly inhabiting tropical seas, which belong to the family Fregatidae. Sailors know them also as man-o'-war birds. Two species occur in Australian seas, chiefly within the tropics; but only the Lesser Frigate-bird (*Fregata ariel*) is known to breed on the Australian coast. Colonies of it are known on Raine Island in northern Queens-

land, and on Bedout and Adele Islands in north-western Australia. W.B.A.

Fringed Violet. See THYSANOTUS.

Frodsham, GEORGE HORSFALL, born at Sale Moor in Cheshire on 14 September 1863, and educated at University College, Durham (B.A., 1888; M.A., 1895; D.D., 1903), was ordained deacon in 1888 and priest in 1889, and up to 1896 worked at Ilkley in Yorkshire. In 1896 he was made rector of St. Thomas's church in Brisbane and chaplain to the bishop of Brisbane, and in 1902 was consecrated bishop of North Queensland (a diocese larger than the British Isles); he resigned this see in 1913 because the tropical climate was found unhealthy for him. Returning to England, he was in 1914 made canon residentiary of Gloucester, in 1920 became vicar of Halifax in Yorkshire, in 1921 was made rural dean of Halifax, and in 1923 canon of Wakefield.

Bishop Frodsham's activities extended far beyond the religious sphere. While in Queensland he took an active part in the foundation of the Australian institute of tropical medicine and in all movements designed to benefit the aborigines, improve secular education, or further social welfare. He was chaplain in the military forces from 1899 to 1910, during the war helped to formulate the A.I.F. education scheme, and in 1922 became senior chaplain in the Northern Command of the British army.

Frogmouths and Nightjars, soft-plumaged, nocturnal birds with long wings, small feet, and very broad bills surrounded by bristles, which feed on night-flying insects. The Frogmouths (Podargidae) are comparatively large birds, peculiar to southern Asia, the Malay Archipelago, and Australia, which build nests of sticks on the branches of trees and lay white eggs. Four species occur in Australia; three are rare birds confined to the tropical scrubs of the north-east; the other, the Tawny Frogmouth (*Podargus strigoides*), is common throughout the continent and Tasmania. This bird is often known as the mopoke, from the belief that it is responsible for the cuckoo-like call, so familiar at night in the bush, which is in reality uttered by the boobook owl (see OWLS). The ordinary call of the frogmouth is a series of deep double notes, sounding like 'oo-oom' constantly repeated. Rarely, however, it does utter a note not very dissimilar from that of the boobook owl. During the daytime it rests on the branch of a tree, sitting lengthwise and not across the bough like most birds. Its mottled plumage and curious, stiff attitude give such a resemblance to a broken-off limb of the tree that it is often difficult to believe it really a bird.

Mopoke.

The Owlet-nightjar (*Aegotheles cristata*), found throughout Australia and Tasmania, is the only species in the family Aegothelidae. These small birds lay white eggs in a hole in a tree, and during the daytime live in holes, uttering a hissing sound when disturbed.

The nightjars (Caprimulgidae), found throughout the world, are represented in Australia by three species, none common. They lay beautifully marbled eggs on the bare ground; by day they usually rest on the ground, hawking for insects at twilight and in the early morning. W.B.A.

Frogs. See AMPHIBIA.

Frost-fish (*Lepidopus caudatus*), a widely distributed species of the family Trichiuridae, occurring in deep water in various parts of the Atlantic, Indian, and South Pacific Oceans. It sometimes appears in considerable numbers along the coasts of New Zealand, and is cast up on ocean beaches during cold, frosty weather. Some writers have affirmed that the fish approaches the shore for the purpose of depositing its spawn in the winter months, but no proof of this is available; it is probable that the fish is forced by abnormal conditions up from the depths that are its natural environment, is rendered helpless by the sudden lowering of outside pressure, and is caught in the waves and cast ashore. This suggestion is supported by the fact that specimens have been observed wriggling helplessly in the water before being stranded, and have even fallen victims to sea-birds which pecked out their eyes, etc., while the fish were swimming aimlessly in the surf.

The frost-fish is long (up to six feet) and ribbon-shaped, with a large mouth and strong teeth; the skin is like burnished silver, and the flesh is excellent eating. In English waters it is known as the 'scabbard-fish.' Barracouta (q.v.) and hair-tails belong to the same family. A.R.McC.

Fruit-growing. Australia possesses few indigenous edible fruits. Except the geebung (q.v.) and the five-corners (q.v.), which are still occasionally sought for in the bush, none are valued by the present white population. In November 1790, however, Governor Phillip reported

that of the native fruits then in season the settlers found two very agreeable to the taste—an acid berry about the size of a currant, which the surgeon considered an excellent antiscorbutic, and which, with a large proportion of sugar added, made excellent tarts and jellies; and a red fruit, also about the size of a currant, which the settlers ate in great quantities. But no attempt was made to cultivate these, and the history of fruit-growing in Australia is a record of the acclimatization of introduced fruits. On his voyage out Phillip secured at Rio de Janeiro seeds and plants which were planted near the present site of the obelisk in Macquarie Place. There is not sufficient evidence to support the story that Richard Johnson (q.v.) planted an orangery at Kissing Point in 1788; but orange plants were included in Phillip's cargo, and some were sent to Norfolk Island when it was occupied in 1788. Orange-culture was very successful in the island during its first occupation; but, when it was reopened as a penal settlement in 1826, the new commandant ordered the trees to be destroyed, as the fruit served as food for runaway convicts. In 1789 Sir Joseph Banks erected a plant-cabin in the *Guardian*, and stocked it with fruit and other plants likely to be useful in the new settlement, but the vessel was lost at sea. In 1794 Banks suggested that a similar cabin should be erected in the *Reliance*, but this plan was not adopted, and the proposed consignment was not despatched until 1800, when one olive, six apples, six black and six white mulberries, 18 Chilé strawberries, two walnuts, two Spanish chestnuts, four pomegranates and several varieties of vine (see VITICULTURE) reached the colony alive, but not all survived transplantation. In 1801 Flinders reported that a plant-cabin was being fitted up in the *Investigator* to take useful plants to Sydney. Caley in 1803 reported that water-melons were much appreciated and apples and figs were growing well, but the fruit that had succeeded beyond expectation was the peach; peach-cider, he thought, would become a good beverage in a few years. In 1806 the governor offered a prize for the best cider prepared during the next peach season, but Surgeon Luttrell wrote in 1807 that attempts to make the cider had been unsuccessful. The principal fruits growing at that time were peaches, apricots, pears, apples, quinces, mulberries, strawberries, raspberries, nectarines (introduced by Bligh), loquats, plums (of indifferent quality), filberts, walnuts, pistachio nuts, and a few olives, oranges, and lemons. Cherries had not yet reached the colony. The excellence of the early varieties of peach (most of which have since died out) and the ease with which they could be grown induced Allan Cunningham (q.v.) to plant peach-stones on his exploratory trips inland, in the hope that they might thrive without further attention and so compensate for the lack of indigenous fruits. A less favourable account of the colonial fruits than those already quoted was given by Pierre Lesson, naval surgeon and corresponding member of the Institut de France, who visited Sydney with Duperrey in the *Coquille* in 1824: '. . . . apples and pears are only middling; the grapes are juicy, but the peaches detestable; oranges good enough, as are figs, strawberries and gooseberries. The governor sent our captain pineapples, quite ripe and as delicate in flavour as those of Tahiti.' Most of the fruit was now being grown at Ryde and in the neighbouring districts along the Parramatta River, which were proving specially suited for citrus fruits.

Until the eighties of last century the distribution of different fruits was determined by natural conditions. By that time Queensland was growing bananas (q.v.) and pineapples in the south-east, and more extensively along the warm coastal belt as settlement moved northwards. The mango, passion-fruit, granadilla, paw-paw, guava, orange, apple, peach, and plum were also grown in suitable localities. In New South Wales the chief producing area was the county of Cumberland and its neighbourhood as far as the Kurrajong on the west and Gosford on the north. In this area citrus fruits predominated. Tropical fruits were cultivated in the north coast district; cherries throve in the volcanic soil round Orange and in the colder areas of the tablelands. Apples, pears, peaches, plums, apricots, and melons were widely distributed. Loquats were frequently grown as a breakwind, as well as for the fruit. In Victoria the apple, plum, peach, apricot, cherry, and pear were the principal varieties grown; raspberries, gooseberries, and currants were also cultivated in the cool, elevated districts. In Tasmania most of the area devoted to fruit-growing was given up to apples; currants, raspberries, and gooseberries were widely distributed, and pears, plums, cherries, apricots, and peaches were also grown. In South Australia the apple, pear, cherry, prune, and berry fruits grew well in the high lands round Mount Lofty and Barossa, in the ranges behind Port Pirie, and in the south-east; citrus and stone fruits were distributed through the low hill country and the plains. The almond and the olive had also been successfully introduced into South Australia. Olives had been sent to Sydney as early as 1800 by Sir Joseph Banks, and may have been introduced into South Australia, together with the vine, from that source. No considerable effort was made to cultivate them, however, until 1844, when truncheons from Marseilles were imported by the South Australian Company. Oil from the berries was sent to the international exhibition of 1851, where it obtained honourable mention for its clearness, colour, and flavour. The calcareous nature of the soil round Adelaide and the warm dry climate well suited the growth of olives, but the industry was hampered by the length of time required before the trees became productive. In 1878 the government of South Australia, to encourage olive-cultivation, published a pamphlet prepared by W. R. Boothby after a tour through the olive-growing districts of Europe. Special attention was given to the industry by Sir S. Davenport. In Western Australia the apple, orange, peach, pear, plum, fig, and apricot were chiefly grown. It is evident that by the eighties practically all known fruits were being grown within the wide range of Australian climatic conditions from the pineapple, paw-paw, mango, and guava of the tropics to the strawberry, raspberry, and currant of colder climes.

But the industry was limited by the small local demand of Australia. There was some intercolonial trade, but this was confined, generally speaking, to a small export of pineapples and bananas from Queensland southward, a considerable export of citrus fruits from New South Wales to Victoria and Tasmania, and a return movement of apples, pears, cherries, plums, and gooseberries. The first impetus to expansion, other than the slow natural development to meet increasing local demands, was the opening up of the apple and pear trade (see APPLES AND PEARS) by Tasmania—and to a less extent by Victoria and New South Wales—with Great Britain at the end of the eighties. When the county of

Cumberland in New South Wales was the only important citrus area in Australia, attempts were made to open up an overseas trade, the first consignment being a cask of oranges and lemons sent successfully to Dublin in 1880. But the risks of transport were still too great for the venture to be worth while on a large commercial scale, and though several shipments were subsequently made no considerable effort was made to place oranges on the English market until 1923. Irrigation settlements, devoted primarily to viticulture and the fruit industry, have been developed since the eighties along the Murray valley and in areas watered by the Goulburn in Victoria and the Murrumbidgee in New South Wales, and by private irrigation schemes in the south-west of Western Australia. To find an outlet for the fruit products of these districts attempts are being made to open up new home and overseas markets for fresh citrus and canned and dried fruits, on the demand for which the future of the settlements largely depends. The irrigated districts are producing good citrus fruits; the Washington navel orange has been specially cultivated along the Murray and Murrumbidgee; choice oranges are also grown by artesian irrigation at the Pera bore near Bourke. The overseas orange trade seems now to be firmly established; Australian growers are specially fortunate in this regard, since their oranges shipped in July-September can be placed on an empty market in Great Britain. In addition to the citrus industry, the settlers are giving much attention to the canning and drying of fruits. In the Murrumbidgee area, whose climate is not so suited to fruit-drying as that of the Murray valley, stone fruits are grown for canning and jams. During the war a special impetus was given to jam-making by the placing of large allied orders in Australia for military purposes. The dried fruit industry was started on a small scale during the seventies and eighties. Tasmania was drying apples; Queensland was endeavouring to place small consignments of dried bananas on the English market, and was making experiments in drying mangoes; in other colonies similar experiments were being made with suitable fruits. But it was not until the settlement of the Murray valley and the south-west district of Western Australia that the industry developed to commercial proportions. Raisins, sultanas, and Zante currants are chiefly treated, but apricots, peaches, nectarines, figs, pears, and prunes are not neglected. Some attention has been given recently to the drying of persimmons. The rapid progress of the industry is generally attributed to the practical monopoly secured to it within the Commonwealth by the imposition of a tariff on all imported dried fruits which can be produced locally, and to its organization for marketing purposes by the formation of the Australian Dried Fruits Association in 1907. This association has been trying since the war to stimulate overseas demands, and has especially urged the adoption by the British government of a scheme of imperial preference which will give Australian growers a competitive advantage over Mediterranean products.

With the development of the fruit industry has arisen a need for its better organization. The new impetus noticeable towards the end of the eighties was supported by horticultural societies in the various colonies and stimulated by newly established departments of agriculture. Fruit-growers' organizations of a loose and changing character were formed, and intercolonial conferences were and are held annually. In 1922 the Commonwealth government called a conference of representatives of the fruit industry, at which it was agreed that a federal fruit council, with an advisory board in each State, should be formed to advise the governments of the Commonwealth and the States on all matters relating to the industry. In 1925 a Fruit-growers' Federation at its annual conference eulogized the work already done by these boards.

In 1922-3 the area devoted to fruit-growing in Australia totalled 275,687 acres of which 73,145 acres were in New South Wales, 86,014 in Victoria, 29,431 in Queensland, 33,003 in South Australia, 19,405 in Western Australia, and 34,689 in Tasmania.

The yield of the more important fruits in the different States was:—

Fruit.	New South Wales.	Victoria.	Queensland	South Australia.	Western Australia.	Tasmania.

Plums (bushels)	242,804	258,117	33,743	123,211	61,406	58,765

The net export of fresh fruits in 1922-3 totalled 106,001,300 lb. valued at £1,012,207; this represented a marked increase since 1918-19 when only 7,152,600 lb. were exported valued at £98,347. The expansion is due partly to an extension of overseas markets and partly to the rapid decline in imports, chiefly of bananas, owing to the imposition of a protective tariff. The net export of dried fruits in 1922-3 was 25,090,263 lb. valued at £1,042,727; of jams and jellies it was 2,453,982 lb. valued at £71,143—a very marked decrease since 1918-19, when military orders were still being placed in Australia. The returns for the net export of canned fruits are not differentiated from those of vegetables, the value of the two being £51,582 in 1922-3.

Fulton, HENRY (1761-1840), an Irish Protestant clergyman, in 1797 held a benefice in

the diocese of Killaloe, but took some part in the rebellion of 1798, and according to the bishop of Derry confessed his guilt under pressure and 'agreed to transport himself for life to Botany Bay.' This was not uncommon at the time; there was grave laxity in securing legal authority to transport captured rebels (see IRISH EXILES), and many of them were merely court-martialled, sentenced to death, and amnestied on condition of leaving Ireland for good. Fulton —who is described by his bishop as a very well-informed man and peculiarly zealous in the discharge of his duties—reached Sydney in the convict transport *Minerva* on 11 January 1800, and caused Hunter some trouble ('we can scarsely divest ourselves' wrote the governor, 'of the common feelings of humanity so far as to send . . . . a Protestant clergyman and family to the grubbing hoe or timber carriage'); on 8 November he was granted a conditional pardon, and on the 20th sent to the Hawkesbury to act as chaplain. In February 1801 he was transferred to Norfolk Island, and for seven years carried out the duties of chaplain there so conscientiously that King recommended him to receive full pay, and in 1805 granted him a full pardon. In 1806 he returned to New South Wales to take over the senior chaplaincy from Samuel Marsden, who was proceeding to England on leave. Bligh took him into favour and made him a member of the civil court. When Bligh was deposed, Fulton openly protested, and was at once suspended by Johnston from his chaplaincy, but was reinstated by Macquarie on 7 January 1810. Later in 1810 he went to England to give evidence for Bligh, and on 31 May 1811 had his position as chaplain regularized (for it had not previously been confirmed in England) by a formal appointment as assistant chaplain to the colony. Returning in 1812, he acted for some months as locum tenens for William Cowper, then head chaplain, and in 1814 was given a charge of his own at Castlereagh on the Hawkesbury and made a magistrate of the colony. By 1818 he had established there a school for the children of well-to-do parents, at which a sound classical education was obtainable; among his pupils was Charles Tompson the first Australian-born poet (see LITERATURE). About 1825, however, the increasing pressure of parish work forced him to close the school. Macquarie had a high opinion of him and, when compelled by orders from England to reduce his stipend (mainly because chaplains of higher standing were being sent out), compensated him with a grant of 600 acres a little north of Mulgoa. In 1828 he launched out as editor of a magazine, *The Blossom*, but it died after the first issue. During the thirties the centre of gravity of his parish shifted from Castlereagh to Penrith, and in 1838 the parish church was erected there. Fulton must have welcomed this as the crown of his labours, and worked there till his death on 16 November 1840. W.J.

Fungi. Under this name some naturalists have included lichens and Mycetozoa (Myxomycetes) but the latter are now considered a class by themselves, and the former are known to be of dual individuality—fungi living on algae; both are therefore in this treatise dealt with under their own names, and only the true fungi are considered here. The larger forms have been well investigated, but many of the smaller kinds have not yet been carefully studied. Some 70,000 species (in 105 families) have been recorded, about 2000 of them being known to occur in Australia. The most familiar are the mushrooms (Agaricaceae) and the touchwoods (Polyporaceae); the common Edible Mushroom (*Psalliota campestris*) has a world-wide range in the temperate zones, and of the Polyporaceae several produce dry rot. Familiar, too, are the vine-mildew (*Oidium*), which belongs to the Perisporiaceae, and the rusts, smuts, and bunts that destroy cereal crops, all Basidiomycetes. While the naked eye can readily distinguish between common species like *Fomes robusta* and *Trametes lactinea*, a microscope is needed to study the internal structure and life-history of any fungus. The methods of fructification are inconceivably various, and families differ amongst themselves as much as any fungus differs from a flowering plant.

The study of the fungi from the pathological and economic points of view is of extreme importance. Plant and animal life are alike widely subject to diseases originating from microscopic parasitic fungi, whose methods of reproduction must be known before any counter-attack can be organized. Such are the Flag-smut (*Urocystis tritici*), the Spring and Summer Rusts (*Puccinia triticina* and *P. graminis*), the Bunt (*Tilletia caries*) and Take-all (*Ophiobolus graminis*), so costly to the wheat-farmer. The Irish Blight (*Phytophthora infestans*) has already, since its first appearance in Australia in 1909, destroyed potato crops over wide areas.

The most serious fungous pest in our orchards is the Black Spot, or Apple Scab (*Fusicladium dendriticum*), and its ally *F. pyrinum*—sometimes known as the Windsor pear blight—which cause the splitting of the fruit, and prevent their uniform growth. A species of *Sclerotinia* attacks beans; *Stereum purpureum* causes the silver-leaf disease in fruit-trees. Peach-leaf curl is caused by the fungus *Exoascus deformans*, so prevalent in cold, wet weather. The shot-hole disease of the apricot is fungous; young apple-trees and nursery stocks are subject to a disease known as powdery mildew or fire-blight, caused by the fungus *Podosphaera Kunzei*. Dead spots and holes in strawberry leaves are due to *Sphaerella fragrariae*. A more insidious foe is the grape-vine disease 'pourridie,' which also attacks other fruit-trees, especially in badly drained land. Appearing as dry rot, it is due to the minute hyphae of a fungus whose fruit may be seen as brackets growing from the bark, or as toad-stools near the roots. *Armillaria mellea*, an edible mushroom, is said to be one of the fungi that produce this disease. The remedy for most fungus-caused diseases is spraying with Bordeaux mixture; but good drainage and a sufficiency of lime in the soil are probable preventatives. Bunt has been most successfully treated in New South Wales with dry copper carbonate, and formalin is largely used as a fungicide in America.

Many human diseases like ringworm and thrush are regarded as fungoid, and fish kept in aquaria or ponds are attacked by a parasitic fungus, *Saprolegnia ferax*. The insect world is affected by the silkworm disease, the bee-fungus and the curious growth known as the Vegetable Caterpillar (*Cordyceps*), of which three species are recorded from Australia and two from New Zealand; a smaller species (*C. gracilis*) appears to be cosmopolitan. Some 160 species have been named, and many wild fictions have been related concerning them. The mycelium of the fungus permeates the tissue of the caterpillar or pupa while underground; arriving at maturity, it sends out fleshy, club-like stems which project several

inches from the ground.

Horse-hair fungus is a sterile mycelium of *Marasmius equicrinis,* that overruns with a blackish, thread-like growth the branches and trunks of trees in the dense scrubs of eastern Australia, the Pacific islands, and India. It has often been mistaken for a lichen. *M. rotula, M. sarmentosus* and *M. obscuratus* are allied species.

Mycorhizal fungi—tuft-like masses of hyphae which infest certain roots—appear to be in some cases actually necessary to the plant, performing the function of root-hairs. This growth is remarkably similar to the hairy-root disease of the apple-tree, which causes stunted root-growth, with excessive production of fibrous roots. These mycorhizal fungi are frequent in peat-loving plants, or in alkali soils that are poor in nitrates; they probably supply atmospheric nitrogen to the plants. They are especially found in Ericaceae, Epacridaceae, Proteaceae, and Coniferae, which inhabit acid situations. Analogous instances of fungal symbiosis with roots are the association of *Boletus granulatus* with *Pinus radiata* (*insignis*) and *P. pinea* and that of *Scleroderma verrucosum* with species of *Quercus.* M. Bernard has shown the co-operation of fungi in the germination of certain orchids, and *Phoma* has been suggested as necessary for the germination of certain heaths (*Erica*). The want of success in germinating seeds of our *Epacris* under artificial conditions suggests a similar economy in the case of *Phoma,* sometimes found on decaying eucalypt leaves.

Near decaying stumps or roots of eucalypts rounded lumps varying in size from a pin's head to a human head, and known to most people as 'blackfellows' bread,' are often found. These are the sclerotia of *Polyporus mylittae,* composed of compacted mycelial strands of remarkable vitality, and are really stores of reserve material intended to provide against the strain of fructification. Another member of the same family (*P. eucalyptorum*) produces the felt-like fungus found on many eucalypts, which resembles the European touchwood; the latter is of commercial importance as a constituent of warm underclothing, and for mixing with saltpetre to form amadou (German tinder).

Fungi surpass all other vegetable products in the richness of their proteids. The following percentages of nitrogen in various dried fungi indicate their nutritive value: *Cantharellus,* 3.22; *Boletus,* 4.7; *Russula,* 4.27; *Lactarius,* 4.68; *Psalliota,* 7.26; morel, 8.23; truffle, 15.35. In comparison with other vegetable foods the percentages of proteids are as follows:—truffle, 35; morel, 36.25; mushroom, 26.31; lentil, 29.33; peas, 28.02; wheat, 16; rye, 12; potato, 1.5. Even the poisonous fungi contain much nutritious food, and would be valuable if their poisonous principles could be eliminated. Some of these principles are volatile, and can be dispersed by high cooking; others are rendered innocuous by the application of vinegar and salt. A considerable number of edible fungi have been tested in Europe where—especially in France and Italy—they are not only used when fresh but are dried for winter use after being passed by special inspectors. Other fungi have medicinal values, or are used for staining wood, while the well-known yeast (*Saccharomyces cerevisiae*) is necessary to the baker and brewer.

See Cheel and Cleland's 'Disease in Forest Trees' in the 1918 *Report* of the New South Wales Forestry Commission, and their 'Australian Fungi' in the *Proceedings* for 1919 of the Royal Society of South Australia.

Fusanus, a genus of the family Santalaceae, consisting of trees or shrubs with small flowers, endemic in Australia with the exception of one species from New Zealand. The calyx-tube coheres with the corolla; lobes 4; stamens each subtended by a tuft of hairs; fruit a globular drupe, with a fleshy outer and a bony inner coat. *F. acuminatus* is the Quandong (q.v.); *F. persicarius,* a small tree, yields a kind of sandalwood. Its roots are used by the aborigines as a food, which is tasteless but nutritious, and is prepared by roasting the root in hot ashes. *F. spicatus* is the 'Fragrant' or 'Swan River' sandalwood of Western Australia. A comparison of its oil with a sample of genuine Madras oil (the sandalwood oil of commerce) shows that the Australian oil has a more fragrant odour, and resembles the Fiji oil obtained from *Santalum yasi.* Most of it, within 250 miles of Perth, has now been cut out. The average annual export of Australian sandalwood for the period 1918-23 was 9642 tons, valued at £157,532. The greater part of this went to Hong Kong and China; the Straits Settlements took about 20 per cent of it. The great bulk of the wood came from Western Australia.

Fustic. See Cudrania.

Fyans. Foster (1790-1870), entered the army at an early age, served in the Peninsular war, and at its conclusion exchanged into the 4th (King's Own) regiment, in which he was commissioned captain in 1826. The regiment reached Sydney with Sir R. Bourke (a former commander) in 1831, but Fyans was left behind to bring out later detachments; he reached Sydney in 1833, was at once despatched to Norfolk Island to report on the condition of the settlement—he distinguished himself there by helping to put down a mutiny and by introducing the first horse into the island—and on return to Sydney was for a time stationed at Parramatta. In 1835 he was appointed commandant at Moreton Bay, where he was host to the Quakers James Backhouse and George Walker; in 1837 he was transferred to Geelong as police magistrate and protector of aborigines, and proved himself a better magistrate than protector. Accordingly in 1840 he was made commandant of 'border police,' a body composed, it is said, of 'refractory soldiers and ticket-of-leave men,' set to keep order in the district between Geelong and Portland Bay. In 1843 he became commissioner of crown lands for Portland Bay, and in 1846 for the Port Phillip district; soon afterwards the border police force was disbanded, and Fyans returned to his post as magistrate, becoming in 1853 sheriff of Geelong. Shortly afterwards he retired from public life, settled down on his estate at Fyansford (Balliang), and died there on 23 May 1870.

Fysh, Sir Philip Oakley (1835-1919), born at Highbury in North London on 1 March 1835, migrated to Tasmania in 1859 to become manager of the Hobart branch of a London mercantile firm. In 1865 he came into public notice as a strong advocate of railway communication between Hobart and Launceston, and almost immediately entered the legislature. He sat in the council as member for Hobart (1866-9) and Buckingham (1870-3, 1884-94), and in the assembly as member for East Hobart (1873-8) and North Hobart (1894-8); he was treasurer in the Kennerley ministry (4 August 1873 to 13 March 1875), premier without office (9 August 1877 to 5 March 1878), premier and chief secre-

tary (30 March 1887 to 17 August 1892), and treasurer in the Braddon ministry (14 April 1894 to 30 December 1898). From March 1875 to June 1876, and in March-December 1878, he was minister without office in the cabinets of the time. During his 1887-92 term of office he was drawn into the campaign for federation, and represented Tasmania at the convention of 1891, but allowed his attorney-general, A. I. Clark, to take the lead in actual work for this cause, preferring himself a more modest measure of tariff reciprocity with New South Wales. Under Braddon's influence he showed more enthusiasm, was elected a representative of Tasmania to the 1897-8 convention, and became a member of the finance committee; when the bill was framed, he threw himself vigorously into the local campaign for its acceptance. At the end of 1898 he left office to take the agent-generalship, and acted as delegate from his colony in procuring the passage of the bill through the Imperial parliament. Returning to Tasmania in 1901, he was elected to the federal house of representatives in that year for his State, and in 1903 and 1906 for Denison; from April 1901 to August 1903 he was an honorary minister under Edmund Barton, and from the latter date to April 1904 postmaster-general under Alfred Deakin. He retired from politics in 1910, and died at Hobart on 20 December 1919. (K.C.M.G., 1896.)

G

Galah. See COCKATOOS.

Gang-gang. See COCKATOOS.

Gannets, large marine birds, mostly inhabiting tropical seas, which belong to the family Sulidae. They are represented on the Australian coast by four species, of which three inhabit tropical seas and the fourth temperate waters. Of the tropical forms the best-known is the Brown Gannet or Booby (*Sula leucogaster*), which breeds in great numbers on some of the islets of the Barrier Reef, and of northern and north-western Australia. The Australian Gannet (*S. serrator*) is common round the whole southern coast of Australia during the winter months; but the only known 'gannetries' in our seas appear to be those on Cat Island in the Furneaux group, Bass Strait, and on Lawrence Rocks off Portland in Victoria. J. Gabriel, when he visited Cat Island in 1908, estimated that about 2500 birds were seated on their nests, and Dr. W. MacGillivray found about 200 nests on Lawrence Rocks in 1900. Three colonies of the same species are known on islets off the North Island of New Zealand. W.B.A.

Gardiner, FRANK (1830-1895?) whose true name was Francis Christie, was born in 1830 at Boro Creek near Goulburn, moved to the Port Phillip district while still a boy, and in 1850 was sentenced to five years' imprisonment in Pentridge gaol for horse-stealing. Within five weeks he broke gaol, escaped to the Bendigo diggings and thence to Goulburn, and in 1854 was sentenced to seven years' hard labour for stealing more horses. After serving about half his sentence he was let out on ticket of leave, settled near Carcoar, and soon became a known and feared bushranger, acting with (or in concert with) John Piesley, another ticket-of-leave man from Bathurst. During 1861 they haunted the roads from Bathurst to the Lambing Flat diggings, occasionally 'sticking up' coaches between Gundagai and Yass. When Piesley left him (to be caught and hanged in March 1862), Gardiner formed a regular gang, with headquarters in the Weddin ranges south of Forbes, and during 1862 carried out a series of raids and robberies which culminated in the Eugowra escort robbery of 15 June, at which he secured about £12,000 worth of coin and gold dust in transit between the Forbes goldfield and the Bathurst banks. This was Gardiner's last exploit; his companions John Gilbert and Ben Hall carried on operations for three years longer, but he disappeared from the colony, and was only discovered in March 1864 keeping a hotel and store at Apis Creek, about 70 miles NW. of Rockhampton in Queensland. He had resumed his proper name 'Christie,' and was carrying on his trade normally and as a decent citizen should. Consequently, when a Sydney detective arrested him and obtained his remand to Sydney on the charge of having committed highway robberies in New South Wales, a good deal of sympathy was aroused for him. At Sydney the charges were more specific; on 17 May he was acquitted of one attempt to murder, but on 8 July was convicted of two armed robberies and another attempt to murder, and Chief Justice Stephen —probably influenced adversely by the expressions of sympathy, so unaccountable to men who had suffered from his depredations—sentenced him to 32 years' hard labour, by making the sentences (15, 10 and 7 years) consecutive instead of—as was the usual practice—concurrent.

Eight years later, Gardiner having meanwhile established a record of consistent good behaviour (and invented a contrivance for improving the selvage of matting made in the gaol), his sisters petitioned Governor Robinson for a pardon, and were supported not only by W. B. Dalley (who had defended him at both trials) but by the then colonial secretary, William Forster. The chief justice refused to recommend any mitigation of the sentence, and the governor would only grant a pardon to take effect two years later and on condition that Gardiner left the colony. In spite of much public and parliamentary opposition, this pardon was made effective on 20 July 1874. Sir Hercules Robinson gave it as his personal opinion that Gardiner could have been allowed to stay in New South Wales without danger, and the chief justice on this occasion recommended the pardon. On the 27th he left Newcastle for China, and crossed thence to San Francisco, where for many years he kept a hotel. The date of his death is uncertain, but was about the middle of the nineties.

Garfishes, members of the family Hemirhamphidae of great economic importance, and always in evidence at the fish-markets, being ranked among our most delicately flavoured table-fishes. Immense quantities are netted annually in our estuaries and along the coasts. They have elongate bodies covered with thin deciduous scales; the lower jaw projects as a spear-like prolongation of variable length, the purpose of which is not evident. In England and America they are known as 'half-beaks,' and the name 'garfish' is used for allied fishes of the genus *Belone*. The Australian garfish is in New South Wales also known as 'guard-fish' and 'beaky.' Garfish move in shoals near the surface of the water, and have the habit of leaping into the air when pursued; some have enlarged pectoral and ventral fins, which enable them to glide through the air for short distances in the same manner as their near relatives, the flying-fishes. Over a dozen species are known from Australian seas, including sea garfish, river garfish, short-beaked and long-beaked garfish. See LONG TOMS.

A.R.McC.

Garran, ANDREW (1825-1901), third son of Robert Gamman, a London merchant, was born at Bethnal Green on 19 November 1825, educated at Hackney grammar school, Spring Hill college, Birmingham, and the university of London (B.A., 1845; M.A., 1848), and in 1850 migrated for his health's sake to South Australia. There he for two years edited the *Austral Examiner* (which, like other venturesome enterprises of the day, was killed by the rush to the Victorian goldfields) and for another two years (1854-5, after an interlude as tutor on a Victorian station) the *South Australian Register*. In 1856 he moved to Sydney to be assistant editor of the *Sydney Morning Herald* under John West (q.v.), succeeding him as editor in 1873 and holding the post until ill-health forced him to resign in 1885. During this time he studied law at the university of Sydney, and in 1870 took the LL.D. degree.

Relieved of editorial work, he threw himself into politics as a free-trader, though never as a partisan, and in 1887 Henry Parkes nominated him to the legislative council. Three years later he proposed the appointment of a royal commission on strikes, of which he was given the chairmanship; when the commission's report resulted in the establishment of a council of arbitration, he became its president, resigning his seat in the council to do so. In 1894, however, he withdrew from the council of arbitration, was reappointed to the legislative council on 19 March 1895, and represented the Reid ministry in that body until 1898. Next to arbitration his chief interest at this period of his life was federation; in 1890 he was the spokesman of those free-traders who set federation above their views on economics, and greatly assisted Edmund Barton in the council debates through which the convention of 1891 came into being. Among other tasks he undertook the editing of the *Picturesque Atlas of Australasia* (1886)—a monumental illustrated description of Australia and New Zealand—and was for many years Sydney correspondent of *The Times*. He died at Sydney on 6 June 1901.

Garran, SIR ROBERT RANDOLPH, son of Andrew Garran mentioned above, was born at Sydney on 10 February 1867, educated at the Sydney grammar school and University (B.A., 1888; M.A., 1899), and trained for the bar, but at an early stage of his career entered public life as a helper in the campaign for federation. Attaching himself to Edmund Barton, he rendered good service to the federal cause as secretary to the drafting committee of the 1897-8 convention, as a councillor of the Federation League from 1893-1900, and as an author. He published *The Coming Commonwealth* (Sydney, 1897) and collaborated with John Quick in producing *The Annotated Constitution of the Australian Commonwealth* (Sydney, 1901) a storehouse of constitutional precedents. In 1901 he was made departmental secretary to the federal attorney-general, and combined that office with that of parliamentary draftsman until 1916, when he was appointed solicitor-general to the Commonwealth—a non-parliamentary and non-partizan office. His value to all the Federal cabinets both as an authority on the constitution and as a non-political adviser of sound judgment and great impartiality has been considerable, especially during war-time, when constitutional and legal difficulties occurred at every turn. He accompanied William M. Hughes, then prime minister, to the peace conference of 1918-9, and his successor Stanley M. Bruce to the imperial conference of 1923. (C.M.G., 1901; Kt. Bach., 1917; K.C.M.G., 1920.)

Garrick, SIR JAMES FRANCIS (1836-1907), born in Sydney in 1836 and educated there, settled in Brisbane soon after the separation of Queensland, practised as a solicitor there (being for several years city solicitor), and in August 1867 entered the Queensland assembly as member for East Moreton. In 1870 he visited England to improve his knowledge of law, studied at the Middle Temple, and on 7 June 1873 was called to the bar. Returning to Brisbane, he was crown prosecutor from 1874 to 1877, and then re-entered politics and joined the Douglas ministry as secretary for lands (6 February 1878) and attorney-general (7 December 1878). From January 1879 to November 1883 he was in opposition, a McIlwraith ministry being in power, but in the latter month he joined Samuel Griffith's first ministry as colonial treasurer (13 November to 31 December), postmaster-general (13 November to the following 24 June), and finally minister without portfolio (24 June 1884 to 13 June 1888); for Griffith, though he had many colleagues whom it was necessary to gratify with portfolios, was loth to deprive himself of the courtly diplomatic skill which was Garrick's, as it was his own, marked characteristic. He therefore in 1885 made Garrick agent-general for the colony, but still retained him in the ministry. During the succeeding McIlwraith and Morehead ministries (1888-90) Garrick returned to Brisbane, but after the coalition of McIlwraith and Griffith in 1890 was reappointed agent-general. He resigned this post in 1895, and died in England on 12 January 1907.

Garrick's political career was that rather of an adviser than of an administrator; while the specifiable results were small, the effect of it on colonial and Australian politics was probably of great importance. He represented his colony at the intercolonial conference of 1883 and the colonial conference in London in 1887. In 1921 the James Francis Garrick chair of law in the university of Queensland was founded under the will of his daughter, Katherine C. Garrick. (C.M.G., 1885; K.C.M.G., 1886.)

Gasteropods. See MOLLUSCA.

Gastrolobium, a genus of the family Leguminosae, consisting of shrubs with opposite or whorled, usually rigid, leaves, found chiefly in Western Australia. The flowers are yellow, frequently with a red keel, usually in clusters; pod oval, leathery. Several species are known as poison-bushes. *G. bilobum* (Heart-leaf Poison-bush), *G. calycinum* (York-road Poison-bush), and *G. ovalifolium* (Bloom Poison-bush —but this name is also applied to an *Oxylobium*, q.v.) are confined to Western Australia. Large numbers of cattle are lost annually through eating these shrubs, the finest and strongest animals being the first victims; the fact that losses chiefly occur during the flowering period indicates that the blooms are the most poisonous part of the plant. Horses, according to the general opinion, are not affected. *G. spinosum*, the Prickly Poison-bush of the Victoria Desert (W.A.), is regarded as poisonous to camels. *G. grandiflorum* (Wallflower or Desert Poison-bush), found right across Australia in northern latitudes, is said to have poisoned large numbers of sheep on the Flinders and Burdekin Rivers.

Gawler, GEORGE (1795-1869), son of Captain Gawler of the 73rd regiment, was born on 21 July 1795, educated at the royal military college at Marlow, appointed ensign in the 73rd regiment in 1810, and served with his regiment in the Peninsular war, being one of the four officers who led the forlorn hope at the storming of Badajos—this gave him his lieutenancy. At Waterloo he led a company against the Imperial guard in the charge which decided the battle. Promoted captain in 1825, major in 1831 and lieutenant-colonel in 1834, he then retired from active service. Meanwhile, in 1819, he had become a devout Christian—a fact which stood him in good stead when the colonization commissioners of South Australia were seeking a successor for Hindmarsh (q.v.); with such men as George Fife Angas to back him, and a letter of high praise from Lord Hill, the commander-in-chief, he easily obtained the governorship of the new colony, and landed at Glenelg on 13 October 1838. As he was both governor and resident commissioner, the disputes which had ruined Hindmarsh's career were henceforth impossible.

But Gawler was soon immersed in troubles of his own. The land regulations, excellent theoretically, had proved unworkable in practice. Landowners stayed in Adelaide instead of employing labour on their country farms; labourers demanded high wages or moved to other colonies where they could buy land at lower rates; the settlement, instead of being self-supporting, had to be fed from outside, and most of its cash went away to pay for food. Gawler found himself obliged to start relief works near Adelaide, which kept the poorer settlers alive, but withdrew them still more from farming. He spent the whole of his private means, and drew bills on the authorities in London for £155,000 more. This stirred the commissioners beyond reason; he had, they said, not only exceeded his authority but jeopardized 'the principle of self-support in South Australia,' and they at once procured his recall. The first intimation he had of it was contained in a letter from George Grey, his successor, who was apparently entrusted with the official letters, and sent Gawler a warning unofficially the very evening he landed in the colony. The blow was severe, and—though subsequent enquiries resulted in his complete exoneration—Gawler never recovered from it; he returned to England in 1842, and devoted the rest of his life to private beneficence. In 1850 he formally retired from the army, and died at Southsea on 7 May 1869. Both before and after his South Australian term he wrote a good deal. In 1833 he published *The Close and Crisis of Waterloo,* in 1837 *The Essentials of Good Skirmishing,* and in 1859-60 was one of the editors of the *Historical Records of the 52nd Regiment.* (K.H., 1837.)—His son Henry, born at Quarndon in Derbyshire, England, on 12 August 1827, accompanied his father to Adelaide in 1838, and to England in 1842, was educated at Rugby and at King's College, London, and was in 1852 called to the bar at the Middle Temple; he returned to South Australia in 1857, and became solicitor and permanent counsel to the lands titles commissioners shortly after the passing of the Torrens act (q.v.). Although never in parliament, he was twice attorney-general—in the brief Waterhouse ministry of October 1861, and for four days in the Boucaut ministry of 1875-6. His knowledge of the Torrens land registration system was so full that in 1870 the New Zealand government invited him to supervise its introduction into that colony. He died at Adelaide in December 1894.

Geebungs are the partly edible fruits of certain species of *Persoonia,* a genus of the family Proteaceae, which consists of shrubs or small trees with entire alternate leaves, ranging from cylindrical and heath-like to very broad and flat. One species occurs in New Zealand; the rest of the genus is endemic in Australia. The corolla segments are free, recurved in the upper portion; anthers shortly stalked and inserted about the middle of the segments; fruit a drupe, with a succulent coat and a bony seed. In several species the tips of the corolla segments are produced into prominent points—a useful character in classification. Some species are ornamental in habit, and are easily propagated from seeds; the succulent coat should be stripped off, and the seeds sown before the bony inner coat hardens. The timber of *P. lanceolata,* one of the first species to receive the name 'geebung,' is sometimes known as 'bonewood,' on account of its hardness. The name is a corruption of the aboriginal name 'jibbong.'

Geese. See DUCKS AND GEESE.

Geijera, a genus of the family Rutaceae, consisting of trees or shrubs, with alternate simple leaves, endemic in Australia. The flowers are small, in terminal panicles. *G. parviflora,* the Wilga of the western plains, is a small tree (20-30 feet) which ranges across the continent from Queensland to Western Australia. An excellent shade tree, it can withstand extreme drought, and is highly esteemed as a fodder-plant for sheep. Its timber is pale-coloured and close-grained, but is subject to gum vein and liable to split. *G. salicifolia* (Ironwood) has a hard, heavy timber recommended for veneering. The bark contains a bitter principle.

Gellibrand, JOSEPH TICE (1786-1837), born in London in 1786 and educated for the legal profession, was called to the bar in London, and in 1823 made by Bathurst attorney-general of Tasmania. Reaching Hobart in company with the new chief justice, John Lewes Pedder, on 16 March 1824, he took a prominent part in establishing the first supreme court of Tasmania, but soon came into collision with both Pedder and Arthur over a point of professional practice. He had drawn the pleas for the plaintiff in a certain case, and later, finding himself compelled as attorney-general to appear against this plaintiff, had transferred his fees to Alfred Stephen; it was not alleged that any failure of justice had resulted, and leading English barristers (including Sergeant Talfourd) approved of Gellibrand's action. Pedder declared that he was not bound by English practice, stigmatized the custom as pernicious, but dismissed a motion to strike Gellibrand off the rolls; Arthur, taking the hint, appointed a commission of enquiry (which included Pedder), and on its report dismissed Gellibrand from his official post, while Bathurst in 1827 cancelled his magistracy for having appealed to the colonial office behind Arthur's back. In that year, therefore, Gellibrand was merely a barrister of the supreme court, free to pursue his own ends. He bought Andrew Bent's newspaper (see BENT, ANDREW) but could not procure from Arthur a licence to issue it. He joined Batman (q.v.) in a proposal to establish a

settlement at Western Port (11 January 1827); but Darling, having just received from his colonizing expedition of 1826 unfavourable reports on the locality, rejected the proposal, and Huskisson's order to maintain the settlement and allow new colonists to join it (20 January 1828) reached New South Wales too late to make any difference. For several years Gellibrand continued to practise his profession, combining it, according to Widowson's *Present State of Van Diemen's Land* (1829), with a little private banking. When Batman in 1835 crossed to Port Phillip it was Gellibrand's carefully prepared deeds of transfer that he put before Jaga-jaga and his fellow-chiefs for signature; the lawyer joined Batman's association, and even drew up a form of government for the new settlement, which might have proved admirable if the territory had not been already part of New South Wales. In 1836 he himself crossed to Port Phillip in an attempt to reconcile the conflicting claims of the Batman and Fawkner parties; returning to Hobart to enlist Arthur (whose nephew was a member) on the association's side, he heard that Bourke was expected in Port Phillip shortly, and hurried back to meet him. Landing in Corio Bay on 21 February 1837, he started with a friend to ride to the Yarra by way of the You Yangs, but apparently lost his way, struck west instead of north-east, and was never seen again, though search parties were in the field for many months afterwards. Years later it was reported (but never definitely confirmed) that relics of Gellibrand had been found in the Otway forest.

A son, WALTER ANGUS BETHUNE GELLIBRAND, was a member of the legislative council of Tasmania from December 1871 to December 1893, and its president in 1884-9. A grandson, SIR JOHN GELLIBRAND (not a son of the last-mentioned), born in Tasmania on 5 December 1872, was sent to England for his education (at King's School, Canterbury and the Royal Military College), entered the army, fought in the South African war as a subaltern in the South Lancashire regiment, rose to be captain in the Manchester regiment, and retired to Tasmania when his battalion was disbanded in 1907. In 1914 he volunteered for service in the A.I.F., was appointed to General Bridges's staff with the rank of major, rose to be D.A.A. and Q.M.G. of two Australian divisions, then to the command of a battalion (the 12th), two brigades (the 6th and 12th), and a division (the 3rd). He was specially distinguished as a trainer of young officers, and was the leader chiefly responsible for the Australian success at Bullecourt in May 1917. On his return to Australia he was made public service commissioner of Tasmania (July 1919), then commissioner of police in Victoria (August 1920), and then returned to Tasmania to cultivate his apple orchard. (D.S.O. and bar, 1916; C.B., 1917; K.C.B., 1919.)

Gemstones. The most important gemstones, other than diamonds (q.v.) and opals (q.v.), found in Australia are sapphires. Sapphires were found near Burrandong in New South Wales in 1851; the present yield is derived chiefly from the Inverell district, which in 1922 produced 3437 oz. valued at £2830 (including small values for zircons and corundum); a few sapphires are found near Tingha. In Queensland the principal centre is on the Anakie mineral-field, whence stones to the value of £35,362 were obtained in 1922; sapphires of inferior quality are also found in the gem deposits at Woodbine and Diamond Hills. Small stones of little, if any, commercial value abound in the tin drifts of the Ringarooma and Portland districts in Tasmania. The total value of the sapphires won in Australia in 1922 was £38,192.

In 1890 emeralds were found near Emmaville in New South Wales, 2225 carats being sent to London during that year. In 1894 turquoises were discovered near Bodalla in New South Wales; they have also been found in thin veins in Victoria. The occurrence of tourmalines (found at Kangaroo Island in South Australia), topazes, agates, rubies, beryls, amethysts, chiastolite, garnets, olivines, and moonstones is also on record, but no returns were given for any of these minor gems in the official figures of 1922.

Gentianaceae, a family of herbs abundant in temperate or mountain regions north of the equator, with a few southern species. Five genera with 24 species are indigenous to Australia. The flowers are ornamental; fruits capsular; leaves opposite, entire. *Gentiana* is a large genus well known in alpine regions. *G. montana* has bell-shaped flowers; the corolla is white with a yellowish base, veined with blue. It is found on Mount Kosciusko and the higher ranges of Victoria and South Australia, extending also to Tasmania and New Zealand. *Erythraea australis* (Native Centaury), like the English centaury and many other species of the family, contains a bitter principle in its vegetative parts; from it is derived a useful tonic, especially valuable in dyspepsia.

Gentiana grisebachii.

Geodesy. Though many surveys have been made in Australia, chiefly in view of land settlement, trigonometrical surveys of high precision are, so far, confined to the three eastern States.

In *New South Wales* about a third of the whole area has been covered with a trigonometrical survey, which was begun in 1867, interrupted in 1884, resumed in 1891, continued until 1916, and then suspended because of financial stringency due to the war.

The first base-line, 5½ miles long, was laid down at Lake George. The standard of length was 'Standard Bar O.I.4,' obtained from the Board of Ordnance in England, and recorded in Clarke's *Comparison of Standards.* The base was measured with three 10-ft. bars of pine, encased in wooden troughs six inches square, with the ends of the bars slightly projecting; each end was fitted with a brass plug, on which a terminal dot was marked. These lengths were standardized every morning and

evening by comparison with the standard bar. Each trough was supported on two 'camels,' by which the three bars could be accurately levelled and placed along the line with the terminal dots in close pairs, leaving a small and constant free space between the bars. This adjustment was made with a double microscope. The difference between lengths obtained by measurement and by re-measurement was 0.54 in. in the 5½ miles. A second base, about seven miles long, was measured at Richmond (west of Sydney) in 1879-80, first with pine bars, then with steel rods. The difference between the lengths so obtained was 0.66 in. The two bases are roughly 130 miles apart. Calculation of the intervening triangulation showed an error of closure on the bases of 1 in 210,000. The subsequent triangulation extends more than 400 miles north-west of a line roughly joining the two measured bases. For the higher purposes of geodesy the survey may, therefore, be said to hang, for the most part, in the air. A third base, 20 miles long, was selected in 1916 at one edge of the survey, and the triangulation was connected to it. Sets of 'invar' measuring apparatus had already been procured, but the suspension of the survey prevented measurement.

The primary stations of the survey are, for the most part, from 30 to 40 miles apart; the secondary rays are usually from 15 to 20 miles long, and the ordinary length of rays to points intersected, but not occupied, is from 5 to 10 miles. At primary stations the observations were at first made with an 18″ altazimuth, latterly with a 10″ universal instrument. At secondary stations a light 10″ altazimuth has been used. The observed direction from one primary station to another of the first order depended on 40 pointings of the telescope, made under various arrangements of the circles of the instrument. For stations of the second order 20 pointings were made, and 10 for intersected points. In 172 primary triangles, the angles of which were all measured with the 18″ altazimuth, the average closing error was 0.71″, and in 29 triangles measured entirely with the 10″ universal instrument the average was 0.61″. In 271 triangles, each of which was formed by two primary stations and one secondary, the average closing error was 1.13″; in 278 triangles formed by one primary and two secondary stations the average was 1.30″; and in 179 triangles formed wholly by secondary stations the average was also 1.30″. This is good evidence of accuracy.

At most primary stations observations were made for latitude and azimuth, and, in some cases, for longitude also. Using Talcott's method for latitude, 50 or more pairs of stars were observed at each station. The 'probable error' of the mean latitude so determined for a station averaged 0.09″. Azimuth was observed by the method used to determine the azimuth error of a transit instrument in a fixed observatory. The transits of pairs of circumpolar stars differing in right ascension by nearly 12 hours were recorded by means of a chronograph. Four pairs were observed on each of five nights under arrangements of the circles of the altazimuth similar to those used for observation of horizontal directions. The 'probable error' of the mean azimuth so determined at a station averaged 0.16″. Longitude was observed on from three to five nights by telegraphic connections with the Sydney observatory. The geodetic latitudes, longitudes, and azimuths of the primary stations were computed by the formulae given at p. 252 of the *Report for 1858* of the ordnance survey of Great Britain. The position of the Sydney observatory, as given in the *Nautical Almanac* for 1890 and onwards, was adopted as origin; the azimuth of the meridian mark of the same observatory, as determined by the government astronomer, is the initial azimuth of the survey. The dimensions of the spheroid of revolution used in the calculations are:—

Major semi-axis = 20,923,134 feet,
Polar semi-axis = 20,853,429 feet.

These appear to have been derived from the early calculation by Clarke of the axes of the earth considered as an ellipsoid (*Memoirs* of the Royal Astronomical Society, vol. xxix), by taking the equatorial semi-diameter corresponding to longitude 152° east. The calculations of the survey have revealed discrepancies between the astronomical and geodetic values of latitude, longitude and azimuth. These, however, are not nearly so large as in India and America, the mountain masses of Australia being comparatively trifling. In the absence of topographic data, and of bases of verification for the bulk of the triangulation, the data provided by the survey have not been systematically treated in relation to the problems of isostasy and the figure of the earth.

In *Victoria* a base nearly five miles long, situated on the Werribee plains, was measured in 1860, and afterwards extended by triangulation for a further 5½ miles. It was measured with three iron bars 10 feet long and 1 inch square, one end of each bar being finished flat and polished, the other as a segment of a sphere of five feet radius, also polished. They were encased in wooden troughs 10 inches square, with hinged tops cut in three sections for the easy reading of the three thermometers resting on each bar, the ends of the bars being exposed for 2½ inches. Their lengths were compared with the 10-ft. ordnance standard lent by the New South Wales government, and later with a standard directly obtained from the British board of ordnance. The three bars were levelled and placed in series at distances of about ¼-inch between the spherical end of one and the flat end of the next; the distance between the two was obtained by passing between them a graduated wedge of bell-metal seven inches long and two inches broad, with faces inclined at angle of ½°. Within ten years the triangulation was extended throughout the colony, south of S. lat. 36°, over an area of about 70,000 square miles; 209 stations of the first order and 267 of the second order were connected and marked, an average number of 170 observations being made at each of the primary stations to determine their positions.

The marking of the boundary line between New South Wales and Victoria, begun in 1870, formed the occasion for the connection of the independent trigonometrical surveys of these States to four common points. The two sets of geodetic latitudes so obtained agreed within 0.25″, and the longitudes differed by from 7″ to 8″ (of arc). When the triangulation was extended westward, to Mount Gambier and Mount Schank in South Australia, a site for a base of verification was selected, but the measurement was not carried out.

The trigonometrical survey of *Queensland* extends approximately from 26°30′ to 29°30′ latitude, and from 151°15′ to 153°15′ longitude, and comprises 74 triangles with a base-line

about seven miles long at Jondaryan. The base was measured in 1884 with two steel tapes 100 feet long, half an inch wide, and a tenth of an inch thick; these were compared with an octagonal steel bar 10 feet long, 1½ inches in diameter, kept floating when in use in a trough of mercury, into which thermometers were plunged to obtain the temperature of the bar. This bar was compared in 1883 with the New South Wales 'Standard Bar O.I.4.' In the base measurements the two tapes were placed in wooden troughs shaded by a board, and a tension of 20 lb. applied by spring balance; five thermometers, whose index errors had been determined, were used along each 100 feet of tape. The troughs were supported on pegs set on even grade with a level, and marks were made in copper disks inserted in the pegs at intervals of 100 feet, the distance between tape ends and marks being measured with micrometer microscopes. Three measurements were made with each tape, and the mean results from the two tapes showed a difference of 0.12 in.

As a rule, ten-inch theodolites were used. The horizontal directions were obtained from two to eight readings made on each of 11 positions of the circle. The closing errors were within 1″ for 29 triangles, from 1″ to 2″ for 29 other triangles, from 2″ to 3″ for 11, and upwards of 3″ for 5 triangles giving an average error of 0.95″. The astronomical datum is the position of the station at Jimbour, as determined by Captain Morris, R.E. and Lieutenant Darwin, R.E. when observing the transit of Venus in 1882. The longitude was determined by telegraphic exchanges with the Sydney observatory. The azimuth datum was that determined with a transit instrument at Bloodwood, this being the apex of one of the triangles standing on the base-line. A minor triangulation of the city of Brisbane was carried out in 1890. The principal triangulation was discontinued in 1891.

In May 1912 a conference of surveyors-general of the States, held at Melbourne, passed a resolution favouring a geodetic survey of Australia to be undertaken by the Commonwealth government, in order to co-ordinate the work of the States, and to provide a common standard of accuracy. A similar resolution was passed by the Pan-Pacific scientific congress, held in Sydney and Melbourne in 1923, to which Great Britain, the United States, France, Japan, and other important nations with interests in the Pacific sent distinguished representatives.

Few *pendulum observations* have been made in Australia. The earliest seems to have been made by Freycinet in 1819, the latest in 1913; all were apparently made independently of the official survey organizations. Some 24 results for the several State capitals are recorded in the reports of the 13th-16th Conferenzen der internationalen Erdmessung.

Before the Sydney observatory was established in 1857, 15 important observations of longitude made near Sydney showed, when reduced to the position of Fort Macquarie, a range of 12 minutes of arc. Captain Cook's determination, made in 1770, differed by 51″ from the value now accepted, and Admiral D'Espinosa's, made in 1793, by 22″.

When, in the sixties, the Sydney and Melbourne observatories were able to determine longitudes with superior instruments, it was found that the 141st meridian, which had been used to define the boundary between New South Wales and South Australia, lay about 2¼ miles east of the position previously accepted. The longitudes on which this result was based were:—Sydney, 10h 4m 48.97s; Melbourne, 9h 39m 54.8s. These values remained practically undisturbed till 1884, when for the first time an Australian meridian was connected with the prime meridian of Greenwich. Singapore had already been connected with Greenwich by telegraphic exchange of time-signals through Alexandria, Aden, Karachi, Madras, and some intermediate stations; and in 1884 the connection of Singapore with Port Darwin by cable, and thence by overland telegraph lines with prominent Australian observatories, completed the telegraphically determined chain of longitudes between Greenwich and Australia. The results were:—Port Darwin 8h 43m 22.49s; Adelaide 9h 14m 20.30s; Melbourne 9h 39m 54.14s; Sydney 10h 4m 49.54s. An independent determination of the longitude of Karachi was completed in 1896 by telegraphic exchanges through Potsdam, Teheran, and Bushire, and in 1906 the arc Greenwich-Potsdam was re-measured. These measurements gave a result diminishing the Australian longitudes of 1883-4 by 0.17s, the new value for Sydney being 10h 4m 49.37s.

In 1902 the Pacific cable was completed, linking Vancouver in Canada with Southport in Queensland, and in 1903-4 the authorities of the Dominion observatory used it to connect Canadian longitudes with those of Australia. As the connection between Canada and Greenwich had already been established, a circuit of longitudes round the earth was thus completed. The closing error was 0.25s, or 0.08s, according as the 1883-4 or the 1906 value by the Singapore route was used, the longitude of Sydney as determined through this new western route from Greenwich being 10h 4m 49.29s.

The development of wireless telegraphy offered a new means of exchanging time signals, and, after some preliminary trials, this means was systematically used in 1920 and 1921. In spite of the very small range of 0.15s among the results derived by cable, the direct connection of the Sydney observatory with Greenwich, by reception of wireless time-signals issued from Lyons on 13 days in April and May 1921, gave for Sydney the mean result 10h 4m 48.98s. This is 0.31s less than the smallest (that via Canada) of the cable determinations. Far more exhaustive was the series of observations of the longitude of Adelaide commenced in June 1920 and finished in July 1921. Comparisons were made with Greenwich, Paris, Ottawa, and Washington of wireless signals issued from Lyons, Bordeaux, and Annapolis, and the mean of 198 separate comparisons gave 9h 14m 19.78s for the longitude of Adelaide. This is 0.27s less than the cable determination through Canada, and is therefore in very close agreement with the wireless longitude of Sydney.

The longitudes of Perth in Western Australia, and of Deakin and Kimberley situated on the 129th meridian, have also been exhaustively observed by comparison with Greenwich, Paris, Sydney, and Adelaide of wireless signals, issued from Lyons, Bordeaux, Annapolis, as well as from Adelaide. The results derived from the several comparisons are in close agreement. Australian longitudes may be said to have now a very firm foundation.

See *Report* of the Conference of Surveyors-general (c. 6832, Melbourne, 1912); P. Baracchi's 'Australian Longitudes' in the *Proceedings* of the A.A.A.S. vol. 14, Melbourne, 1913; and G. F. Dodwell's 'Australian Wireless Longitude Determinations' in the *Report* of the Pan-Pacific Congress of 1923.

Geoghegan, Patrick Bonaventure (1811-1864), born at Dublin and educated at the Irish Franciscan Colleges at Lisbon and Coimbra (where he was ordained priest), after some years of mission work in Dublin volunteered for the New Holland mission, and sailed with Dr. Ullathorne in 1838. In May 1839 Bishop Polding transferred him to Melbourne, where on 19 May he celebrated the first mass recorded at Port Phillip. His strenuous work built up the church there so strongly that within eight years it was constituted a separate diocese, Father Geoghegan becoming its first vicar general. On 8 September 1859 he was consecrated bishop of Adelaide by Archbishop Polding in the church of St. Francis, Melbourne, which he himself had built. In his diocese he remained the 'diligent and earnest missioner, cheerfully spending himself for the good of souls,' whom Dr. Polding esteemed so highly; but ill-health overtook him, and he died suddenly on 9 May 1864, while on a visit to Kingstown in Ireland. E.M.O'B.

Geography, Economic. It is by no means sufficient for a geographer to state where a given product may be obtained; he should be able to say why it occurs there rather than in many other areas which at a first glance are equally suitable. Hence in this description of the resources of Australia the causal aspect will be emphasized.

Note the position of Australia in the world-map; perhaps the most useful map is one which shows the climatic regions as modified by the writer from the plan suggested by Herbertson (see Taylor's *Australian Meteorology*, p. 281). Australia is so situated along the tropic of Capricorn that a little over one-third of it is within the tropical zone. Similarly situated regions, with a considerable extent along the tropic, are found in South America and southern and northern Africa; in Asia and in Central America along the tropic strongly indented coasts preclude any close resemblance to Australia as a whole. But the high plateaux of southern Africa (and those, not quite so high, of South America) have no representatives in Australia; and it is in northern Africa that we find perhaps the most general resemblance to our own continent. If we superpose an inverted map of Australia over one including the Sahara and Mediterranean, we see how closely our fertile southern areas agree with the Mediterranean lands, while our interior corresponds in general character (though luckily not in relative extent) with the Sahara. Moving our inverted map eastwards along the tropic, we find a close resemblance between our tropical areas and those of the Indian peninsula. It is, therefore, with the Mediterranean, the Sahara, and southern India that we should compare our three main divisions of temperate, central arid, and tropical regions.

With regard to the temperate region it may be noted that by virtue of their winter rain and warm, dry summer our southern lands are well adapted for wheat. Yet Italy produces almost as much wheat as the whole of Australia, and Italy, Spain, and Algeria together in 1914 grew just twice as much.

Along the tropic in all three areas under comparison occur large arid tracts, whose extent is directly proportioned to their average distance from the sea. Thus the Sahara is the greatest desert which, owing to the vast extent of equatorial Africa, approaches the equator most closely. The Australian desert, the second in extent barely reaches into tropical areas. The Indian desert (or Thar), owing to the comparatively slight width of India, is the smallest of the three. As they are similarly situated, so they have a similar origin, being due purely to the average isobaric distribution throughout the year. They all lie under the belt of high pressure, which is inevitably a region of descending air that becomes warmer and drier as it descends. On the equatorial side of this belt is the region of easterly trade-winds, by far the most important and extensive of all the permanent winds. The western areas of the largest land-masses, therefore, so far as they lie in the trade-wind belt, are swept by winds that have long since left the ocean (the natural source of their water-contents), and are approaching the equator; these winds, steadily becoming warmer and drier, absorb moisture from the land beneath them instead of giving it out, and so produce deserts.

A desert, it must be remembered, is not usually devoid of plants and covered with shifting sand. Even in the Sahara we get immense stony plains, and a sparse *Acacia* flora in many respects like that of central Australia. The word 'desert' is used here for lands at best only capable of very sparse settlement, and possessing a low rainfall—which in Australia seems

Map showing net Rainfall.
Black areas are those in which rainfall exceeds evaporation.

to approximate 8 inches in the south (with a reliable winter rainfall), and 16 inches in the north (with an unreliable rainfall and great evaporation). Vegetated sand-ridges under these conditions are quite uninhabited. Elsewhere sparse stock may flourish. The exact boundary is very debateable. In certain favoured areas (e.g. near Southern Cross in Western Australia), where the rainfall is assured and falls in the required season, a considerable crop of wheat can be grown, even though the total fall for the year is little more than ten inches. But these exceptional areas are relatively of very small extent.

The tropical division of Australia is comparable with peninsular India. The climates of Calcutta and Townsville are extremely alike as regards both rainfall and temperature. The climates of Wyndham in Western Australia and of Tinnevelly in the extreme south of India have also much in common; they appear to hold the record for a high average annual temperature (84° Fahr.), accompanied by a heavy monsoon rainfall (30 to 40 inches) and high humidity in summer.

In Tasmania we have a land-area cooler than any of those mentioned above, which corresponds very closely in climate and resources to Brittany and southern Britain.

Australia is therefore a continent of almost

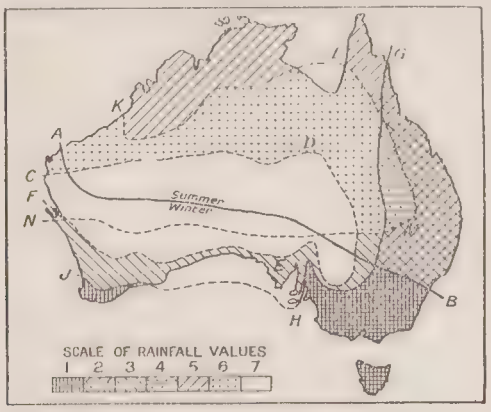
infinite variety. In the following table are indicated foreign regions enjoying similar conditions (homoclimes), Herbertson's scheme being used as a basis:—

Homoclimes with Australian Regions.

Australia.	Type of Rainfall.	Typical Resources.	Foreign.
Tasmania	Cool, uniform ...	Farming, dairying, forestry ...	Britain, British Columbia.
South coast-lands of Australia	Chiefly in winter ...	Wheat, vines, wool, dairying...	Spain, Italy, Turkey, Algeria, California, Chile.
New South Wales coast ...	Heavy, warm, uniform	Cattle, maize, vine, (cotton, tea)	Natal, Uruguay, Virginia, eastern China.
Western plains of New South Wales	Slight, warm, uniform	Wheat, wool, cattle	Inland Argentine, Mississippi Valley.
Northern monsoon area ...	Summer rains ...	Sugar, rice, cattle, wool ...	India, eastern Brazil, Portuguese East Africa.
Warmer arid area	Some summer rain ...	Pastoral	Kalahari Desert, Thar, northern Sudan.
Cooler arid area	Some winter rain ...	Pastoral (some dry-farming)...	Northern Sahara, California and Mexican Desert.

The rainfall map of Australia shows that zones of heavy rainfall surround the arid central and western regions. This map, however, since it does not indicate many essential features of the rainfall, is apt to be very misleading. Settlers need to know the character, reliability, and season of the rainfall even more than its annual amount. Consider four districts which have approximately 15 inches per year—Roebourne, Northam (both in Western Australia), Tennant's Creek in the Northern Territory, and Cobar in New South Wales. None of these are debarred from settlement by excessive heat or dryness; but two of them will never support a large population. The Roebourne region is marked by the most unreliable rainfall in Australia; in 1891 it received only 0.13 inch, while in 1900 there fell 42 inches, and its average rain-variability has been computed at 43 per cent. Tennant's Creek is chiefly characterized by an absolutely dry period of seven months (April to October); at Cobar the 15-inch rainfall is spread out almost uniformly through the year; Northam receives practically all its 15 inches during the wheat-growing season, and is district than Cobar, which is only barely within consequently a much more important farming the dry-farming area.

These boundaries are shown below, and an attempt is made to classify Australian regions according to their characteristic rainfalls. The



most useful type of rain is spread over the whole year, fairly abundant, and not liable to vary from the normal. This type is included in class 1 (winter maximum) and class 2 (summer maximum); class 3 includes the area of moderate and reliable rainfall chiefly occurring in winter. The above are all agricultural regions. Of great pastoral value is class 4 in central Queensland, which has a well-distributed rainfall—not, however, very reliable. The purely monsoonal regions of the north form the next two classes as they are reliable (class 5) or erratic (class 6). The arid region (under ten inches) includes the southern portion, where such rains as fall are fairly constant, and—the worst region of all—the unreliable northern arid moiety. From this map, used in conjunction with an average rainfall map, the pastoral and agricultural capabilities of any large area in Australia can be ascertained with fair accuracy.

A factor of equal importance in a study of economic geography is the distribution of the geological formations. The geology of the Commonwealth is treated more particularly elsewhere, but a brief note about it is relevant here. From an economic point of view Australian formations can be divided into four major groups, (1) the western peneplain (i.e. level or undulating surface, worn down by the long-continued action of rain and rivers); (2) the highly-folded early Palaeozoic highlands; (3) the moderately-folded Permian and Triassic coal-measures; (4) the level-bedded Mesozoic and Tertiary deposits. Their general relations to economic problems are shown in the following table:—

Group 1.

Geological formation.—Western peneplain, comprising most of Western Australia and the western portions of the Northern Territory and South Australia. Largely Palaeozoic rocks (pre-Cambrian in SW., Devonian and Carboniferous in NW., Cambrian in NE.). *Topography.* Undulating, low plateau of about 1000-feet elevation. Few high mountains, and no rivers except along the coast. Numerous shallow salt lakes. Sand-ridges characteristic of centre. *Climate.* Situated along the tropic in the trade-wind area. Generally arid, but with good seasonal rainfall to north and south. Better rainfall near Macdonnell Ranges. *Economics.* Much true desert in centre. Valuable saltbush and mulga country, gradually merging into grass-lands in the south and north. Valuable ores in the ancient rocks of SW. and NW.; ores rarer elsewhere.

Group 2.

Geological formation.—Palaeozoic highlands along the eastern and south-eastern coasts. Cambrian rocks in the Flinders Range. Largely Ordovician to Carboniferous on the west of the Divide (Secondary rocks involved in the Blue Mountains and southern Queensland). Large masses of granite are abundant, much faulted and penetrated by dykes, etc. *Topography.* Usually broad uplifted massifs, often flanked by faults and dissected by deep valleys, often they form the

divide between the Murray and the coastal streams. The chief uplift was probably in late Tertiary times. Many lava-flows associated with the uplifted areas, and in part constituting the Divide. Rise to 7300 feet in Kosciusko. *Climate.* In the north a heavy rainfall, as they intercept the permanent south-east trades. Elsewhere good rainfall, partly owing to uplift of moist on-shore winds. Climate greatly ameliorated in northern regions of Atherton plateau, Darling Downs, New England, etc. Alpine condition in the Monaro, Bogongs, etc., in SE. *Economics.* Many important metalliferous deposits are exposed in these ancient uplifted rocks. Chief dairying districts of Australia. Important forests. On the inner flanks of the southern highlands are grown the chief wheat-crops, and in the valleys and littoral of this group is the bulk of the population.

GROUP 3.

Geological formation.—Coal-bearing strata (chiefly Permo-Carboniferous and Triassic in age). Mostly level-bedded sandstones and shales, which occupy basins in the strata of group 2 along the eastern highlands. *Topography.* An integral portion of the highlands of group 2. In some cases the softer coal-measures have been subject to greater erosion, and so have determined the topography; e.g. Hunter valley and Blue Mountain valleys. Otherwise they partake of the general warping and uplift. *Climate.* Too small in area to have a marked climatic effect. Still, certain major gaps in the highlands correlate the coal-measures with the rainfall (e.g. in the Hunter valley). *Economics.* In the future large manufacturing industries will attract a dense population along the coal belt. This is already shown in the crowded condition of the lower Hunter valley.

GROUP 4.

Geological formation.—Water-laid sediments, which have not been folded or crumpled. They include deposits of Cretaceous and Tertiary age, and form a belt of lowland from the Gulf of Carpentaria to the Murray mouth. Around the latter is the largest area of Tertiary deposits. *Topography.* The rolling country forming the Great Artesian Basin is Cretaceous. The farther plains in the Riverina and lower Murray basin are of Tertiary age. Immense areas of superficial Tertiary deposits cover older rocks from the Barkly tableland in the Northern Territory to Eucla in the Bight. Rivers large, but rarely permanent. *Climate.* Rainfall primarily controlled by distance from the sea. In the north a summer rainfall due to tropical 'Lows.' In the south, Antarctic Lows give rain. In the centre there is very little dependable rain; what there is is largely due to thunderstorms. *Economics.* The great grazing country of Australia. The west is opened up by artesian wells. Opals are practically the only mineral, except where inliers of Palaeozoic rock are exposed.

WESTERN AUSTRALIA.—*Area*: 975,920 sq. m. (364,000 tropical, 611,920 temperate). *Rainfall*: arid area (under 10 inches) about 500,000 sq. m.; tropical rain area (over 10 inches) about 350,000 sq. m.; temperate rain area (over 10 inches) about 125,000 sq. m. *Population* (1921): 332,732 whites, 25,587 aborigines. *Chief Towns*: Perth (155,592), Fremantle (25,534), Kalgoorlie (19,213), Bunbury (4475), Geraldton (4174), Albany (3976). *Stock* (1922): cattle, 939,596; sheep, 6,664,135. *Chief Products*: wheat (1922-3), 13,857,432 bushels; timber (1922), 149,158,000 super feet; pearls and pearl-shell (1922), £215,385 in value; gold (1922), 538,246 fine oz.; silver (1922), 118,696 fine oz. *Railways* (1921-2): 4867 miles. For statistics of stock, products, etc., not given here see separate articles on HORSES, SHEEP, etc.

Topography.—The lozenge-shaped block constituting Western Australia, and forming one-third of the continent, is a splendid example of a peneplain. It is an extremely ancient land-surface, lying almost wholly between the 1000- and 2000-ft. contours. There are only two large areas exceeding 2000 feet. One in the centre of the State extends from Nannine to Lake Wells, and may be called the Wiluna uplands. The other, more imposing, lies between

the upper Fortescue and upper Gascoyne rivers, rises to over 4000 feet in Mount Bruce, and is bounded on the north by the well-marked scarp of the Hammersley Range. In the Kimberley regions are other local elevations (Mount Hann, 2800) which exceed 2000 feet. A well-marked ridge in the extreme south (the Stirling range), which rises sharply to 3640 feet, is a mass of old quartzites sharply differentiated from the surrounding granites and gneisses.

The mountain 'range' of chief economic importance runs parallel to the coast somewhat east of Perth. Like so many of our ranges, the Darling Range is really a scarp marking the edge of a fault, or the slope of a Tertiary fold. Here it separates the coastal plain, built of Tertiary sediments, from the extremely ancient gneisses, etc., of the great peneplain to the east. It rarely rises much above 1000 feet.

Hydrography—Coast.—Just west of the Territory border lies Cambridge Gulf, with Wyndham at its head. Proceeding westwards, the Kimberley coast contains many deep inlets (really drowned river-valleys) which are affected by abnormal tides; near Glenelg River there is a 36-ft. rise. King Sound at the mouth of the Fitzroy separates this 'ria' region from the less indented and shallower shores to southwards; it is notable for the great velocity (8 knots) of its tidal streams. The eastern portal of the Sound is Cape Lévêque, surmounted by a light. Roebuck Bay forms a good harbour for the town of Broome, the chief port on this coast. Here starts the cable to Java. Far-

ther south lies the Ninety-mile Beach, and the next important settlement is Port Hedland. Here and at the neighbouring ports, Cossack and Onslow, are lights visible over 10 miles. Exmouth Gulf is a wide indentation of little importance, passed just before reaching North-west Cape. There is a light on Vlaming Head at this cape. Coral-reefs make the navigation dangerous along the coast, and extend south to Houtman's Reefs off Geraldton.

Shark Bay is the chief indentation, and is divided into two by the low Peron Peninsula. The bold headland of Point Inscription, on Dirk Hartog Isle to the west of the bay, is crowned by a lighthouse. Dorre and Bernier Isles also separate Shark Bay from the Indian Ocean. Geraldton on Champion Bay has a regular coastal service to Fremantle, with which it is also connected by railways via Moora and Wongan. Rat Island, off Geraldton, has been worked for guano. Near Dongara, a small port on the Irwin River, coal has been found; and 100 miles south, at Jurien Bay, a curious submarine spring has been noted 600 feet from the shore.

Fremantle, the chief port of the State, is approached round Rottnest Island, which carries a powerful light visible 23 miles. Gage Road is the anchorage at the mouth of the Swan River. The next noteworthy inlet is Geographe Bay, north of the uplifted granite 'horst' of Cape Leeuwin. On its shore are Bunbury and Busselton, while to the west is Cape Naturaliste, a fine headland 400 feet high. At the extreme south-west of the continent is Cape Leeuwin, a somewhat insignificant promontory surmounted by a high lighthouse visible 21 miles. Along the south coast the cliffs are high (Point Nuyts 647 feet) all the way to King George's Sound. At the entrance to the latter is Breaksea light, which guides the shipping into Albany. East of this town there is very little settlement, except at Hopetoun and Esperance, and near the latter place the coast is fringed by the islets of the Recherche Archipelago. The shores of the Bight consist of abrupt cliffs from 200 to 400 feet high. Telegraph stations are situated at Eyre and Eucla, and the latter possesses the only anchorage for nearly 400 miles. The grand sweep of the Bight may be due to faulting, and to marine erosion acting on a uniform series of somewhat soft horizontal beds.

Rivers.—The rivers of the State are on the whole of little importance, but in the Kimberleys there are many fine streams, the Fitzroy being about 400 and the Ord about 300 miles long. These maintain a fairly strong flow, owing to the heavy summer rains, but are not of much use for navigation. The Fitzroy is blocked by sandbars and snags; the Prince Regent River to the north seems to have greater possibilities. The De Grey, Fortescue, Ashburton, and Murchison, though prominent features on the map, carry little water except after occasional floods. The Swan, Murray, and Blackwood above tidal limits are of no importance for navigation.

A vast proportion of Western Australia is totally devoid of rivers. Shallow valleys, resembling the wadis of the Sahara, carry the waters of occasional thunderstorms, but these are soon absorbed by the immense extent of thirsty sand. The lakes so profusely scattered on the map are shallow saltpans, and rarely contain water.

Artesian Water.—Of great importance, however, is the underground water, which is fortunately widespread, and is reached either by artesian or by shallow wells. Artesian water is developed in several basins. The Perth district water-supply is in part obtained from about 50 bores, over four million gallons a day being obtained at Leederville from a bore just over 2000 feet deep. In the dry country behind Shark Bay stock are benefited by 69 bores put down between Onslow and the Murchison. A large basin round Broome, which has been prospected (the town itself obtains its supply from this source), extends to the east considerably beyond Derby. The Eucla basin supplies somewhat brackish water along the transcontinental railway.

Wells.—The hydrography inland can be gathered from Talbot's report of his survey of Canning's stock-route. Some 50 wells were sunk along the line from Wiluna to Hall's Creek. There are no rain-gauges in this area, but, judging from the vegetation, the annual rainfall is not much over 12 inches. From Wiluna to Weld Spring sand-ridge, clay-pan, and mulga country occur, but natural waterholes are to be found every 20 miles or so. For the first half of the stock-route (800 miles) the wells were sunk to a depth varying from 12 to 104 feet, the average being about 36 feet. These yielded on an average about 1000 gallons per hour, though the flow varied greatly.

In the northern half of the route Canning made use to a greater extent of cleaned-out native wells and rock-holes, and well-sinking was not so necessary. At Mujingerra (near 23° S.) a most peculiar natural well occurs in the travertine; it leads to a cave about 150 feet long, containing a large pool of fresh water about four feet deep.

Talbot concludes as follows: 'Although at some future time the country along the lower portions of the Sturt River may become settled, the country along the stock-route beyond' (i.e. south-west from the Sturt) 'is never likely to become occupied by pastoralists.'

Population.—In a new country like Australia the economic factor is almost wholly responsible for the distribution of population. The boundaries between the States either are natural or follow geodetic lines. No strategic requirements, no relics of previous conquest or mismanagement, have complicated the political geography of Australia; we may therefore take the natural distribution of the population as a trustworthy guide in surveying the State's resources. There is a compact knot of 155,592 people at the metropolis—nearly one-half of the whole State; surrounding this district, and feeding it, are four well-populated blocks, the Northam district in the north-east (40,000), the wheat-belt running south-east to Albany (55,000), the coastal belt running south to Leeuwin (30,000), and the Geraldton district to the north with 8000 settlers. This well-settled area within the 10-inch rain-line has been conveniently termed 'Swan-land,' and contains 86 per cent of the population. Extending far into the arid region are the Kalgoorlie goldfield towns, holding a group of 30,000 similarly interested people. Parallel to them to the north is the Murchison group (4000). Yet farther north is the Pilbara field, with 1500. In the whole of the rest of the State, comprising four times the area already discussed, there are probably not 8000 inhabitants, and they are almost all clustered along the coast at Eucla, Esperance, Carnarvon, Broome, Wyndham, and similar places.

Products.—By far the most important product of Western Australia is *gold*, the output of

which exceeds in value 147 millions sterling, mostly produced in the last 30 years; more than half of this came from the Kalgoorlie district, which contains the famous 'Golden Mile.' The geological aspects of the goldfields are described elsewhere, but their distribution, lines of communication and centres of settlement belong properly to geography. If we draw a circle centred 60 miles west of Menzies, with a radius of 250 miles, we shall enclose all the most important goldfields. This area is a granite peneplain of great age, so eroded that the 'roots' of the formations are laid bare. The ore-deposits are always found near yet older inliers of gneiss and shattered eruptives (greenstones). These auriferous belts run from NW. to SE. in a parallel series, each belt being much interrupted; they have been 'tapped' by two railways crossing them at right angles. Along the eastern railway we come first to the Southern Cross mines in the Yilgarn field, then, after a barren stretch, to the famous Coolgardie, Kalgoorlie, and Kanowna series, with Norseman to the south. Running north along the belt, the railway taps the Menzies, Niagara, and Leonora mines, and the Laverton group E. of them. In the Murchison district is a similar series, served by the northern railway. First come the Yalgoo mines; then, after an interval of bare granite, the Mount Magnet, Daydawn, and Cue mines; in the third belt are the Meckatharra and Sandstone mines; farthest east, beyond the railway, is the Wiluna field. The Pilbara region behind Port Hedland is the only outlying goldfield of importance, but ranks below the southern fields; its two chief centres are Marble Bar and Nullagine, the former connected to the port by rail. Kimberley in the far north (Hall's Creek, etc.), Ashburton and Gascoyne in the north-west angle of the State, and Phillips River (served from Hopetoun on the south coast), are not great gold producers.

Minerals other than gold are of much less importance, but may conveniently be mentioned here. In the SW. corner of the granite peneplain, 130 miles south of Perth, is the Greenbushes *tin* field, where tin to the value of half a million has been produced. Unlike the goldfields, it is situated in a flourishing farming district with a rainfall of over 30 inches a year. A little to the north is the Collie *coal* field, also on a branch from the south-western railway. It is the only important coal-field west of Melbourne, and its geographical position gives it a special value. Another southern mineral field is situated behind Hopetoun, much *copper* being obtained from the Phillips River district. In the Pilbara fields in the NW. the tin and copper together have been as valuable as the gold, both groups having produced well over a million sterling.

It will be noticed that on the whole the valuable minerals occur in the arid portions of the State. This has resulted in the rapid opening up of much of the interior, so that, apart from mining, large areas of country carry some stock. Unfortunately the geological character of the country changes very greatly N. and E. of the great goldfields, making it very improbable that auriferous deposits on a large scale will be discovered in the unsurveyed centre. No doubt in the future the stock areas will expand farther eastwards, but for many years the central-eastern section of the State will remain unoccupied.

It is convenient to deal with the distribution of stock next, though wheat is second to gold in order of importance. Both as regards cattle and sheep this State, despite its dominating area, is only fourth in the Commonwealth. Stock of some sort is carried almost everywhere except in the arid centre. *Cattle* are most numerous in the north, and sheep along the western coast. The chief cattle region is in South Kimberley, along the Fitzroy and Ord Rivers, where there are 523,000 out of the State's total of 939,596 (1922). The north-western (Pilbara, etc.) and Peak Hill regions account for about 150,000 head. The cattle are driven to the ports by definite tracks, along which permanent wells are maintained by the government. Other stock-routes run from Broome and the north-west to more southern ports. Along the littoral both N. and S. of Perth are the chief dairy herds, but here sheep are of more importance. It will be seen that the cattle occupy the rougher and less accessible portions of the State. This is natural, since they can cover more ground in grazing, and can be driven longer distances than sheep. As railways are extended, and water-supplies are improved, sheep will replace cattle in many districts, as they have done all over Australia. The cattle-station is the pioneer of settlement, here as elsewhere. The relation of cattle to rainfall is not very close; but they do not seem likely to spread into the driest eastern areas, which are largely covered with sand-ridges. Here the rainfall is perhaps only seven or eight inches—but there are no rain-gauges in these districts, and probably no portion of Western Australia receives much less than seven inches.

About half the *sheep* are grazed in the well-watered south-western corner ('Swan-land'), especially near Geraldton and Katanning. These districts are, however, devoted to many other industries, and it is on the north-western coast near Carnarvon, and in the Pilbara district, that sheep are of paramount importance. Even so far north as Broome and the Fitzroy basin there are 165,000 sheep; it is evident that the tropical climate suits them well enough. As yet sheep have not penetrated far inland, except near the railways; the lack of permanent water is the chief obstacle. Since they do so well near Carnarvon, with an average rainfall of less than 10 inches, it is obvious that well-sinking and dams will gradually open up many square miles of empty country, whose rainfall is little below that at Carnarvon and probably no more erratic.

Interesting features of the pastoral country are the rabbit-proof fences. The chief of these extends from the north coast near Port Hedland to the south coast near Hopetoun, a distance of more than 1000 miles. Another (earlier) fence runs from Hopetoun north to Yalgoo and thence to Northampton on the west coast. These fences are inspected continually along their whole length and have to a considerable extent protected the pastoral areas from the rabbit-plague of eastern Australia.

Camels are an important asset in an arid State. There were 6473 head in December 1922, spread rather evenly throughout the outlying districts; most, perhaps, are to be found between Pilbara and Yalgoo.

Wheat-growing has quadrupled its production in the last 10 years. It is absolutely controlled by the rainfall, lying almost wholly between the isohyets of 10 inches and 30 inches (for April-October). York may be taken as the centre of production; thence it spreads north to Geraldton and south to Katanning. The

best areas seem to be those that receive from 15 to 20 inches in the cooler months. As pointed out previously, 'Swan-land' is admirable for wheat, in that the rainfall is the most reliable in Australia and falls almost wholly just when it is most required. A great development of railways has taken place of late years in the wheat-belt. The new northern line (from Mullewa to Northam), and all the numerous branches running eastward from the southern line (i.e. at York, Narrogin, Wagin, Katanning, and Tambellup) are primarily concerned with opening it up. As a whole it yields, by the present somewhat primitive methods, about 12 bushels per acre in a fair year.

Western Australia has the largest *timber* export industry of all the States; 227 million feet (super) were cut in 1914, all from the hardwood forests of the south-western corner; the industry suffered greatly during the war, but by 1923 had recovered to the extent of cutting 149,158,000 super feet. The timber-belt (that part of it at least from which timber is exported) is practically confined within the 20-inch rainfall line. But even with a rainfall of less than 10 inches the goldfields contain a fair growth of eucalypts that have become adapted to desert conditions.

The two chief timbers are jarrah (*Eucalyptus marginata*) and karri (*E. diversicolor*). The jarrah belt lies along the Darling scarp from Perth to the south coast. The trees average about 100 feet high, and are used all over the world for wood-blocks, pipes, etc. Karri extends chiefly along the south coast from Cape Leeuwin to Albany, especially in the Blackwood and Warren valleys. It is a larger and more graceful tree than the jarrah, and is used for similar purposes. The forest sawmills are most numerous along the railway branches south-west of Geographe Bay. Karridale, Augusta, Donnybrook, Pinjarra, Busselton, and Bunbury are largely interested in timber export. White gum (wandoo) is a smaller but very useful tree which grows along the southern railway. Sandalwood (*Fusanus*), a tree usually about 20 feet high, supplies an important export; it grows in similar country throughout the wheat-belt, as well as farther north. Of the total Australian export, valued in 1922-23 at £110,824, 90 per cent comes from this State. Two gums widely spread through the southern goldfields are the salmon gum and gimlet gum; they flourish where the rainfall is in the neighbourhood of 10 inches a year, and are invaluable for mining needs.

Apples grow splendidly in the karri district, south of a line joining Bunbury to Cranbrook. Many other orchards are scattered through the jarrah belt, where oranges also thrive. The *vine* country lies between the wheat-belt and the orchard-belt, more particularly in the triangle formed by Bunbury, Cranbrook, and Gingin. *Whaling* stations established at Point Cloates (near Onslow) and at Albany have revived a bygone industry. More important are the *pearling* grounds (*a*) in Shark Bay, with a centre at Denham, (*b*) along the coast from North-west Cape to Derby, with a centre at Broome. In 1922 221 small vessels and 1571 men were employed, most of them Japanese.

Northern Territory.—*Area*: 523,620 sq. m. (426,320 tropical, 97,300 temperate); arid area (rainfall under 10 inches) about 140,000 sq. m. *Population* (1921): 3867 whites, 17,349 aborigines. *Chief Town*: Darwin (1398). *Stock* (1922): cattle, 760,766; sheep, 6161. *Chief Products*: pearls and pearl-shell (1921-2), £1106 in value; gold (1921-2), 115 fine oz.; tin (1921-2), 79 tons. *Railways* (1921-2): 199 miles. For statistics of stock, products, etc., not given here see separate articles on Horses, Sheep, etc. A map is given on p. 511.

Topography.—The north-central division of the Commonwealth is geographically a portion of the western peneplain. It has therefore all the characteristics of tropical Western Australia, save that the useless arid portion is much smaller in extent. Speaking generally, the northern half lies between the 500- and 1000-ft. contour, while the southern half is mostly over 1000 feet in elevation. There is only one important mountain area, but this is one of the most definite series of ranges in Australia. The Macdonnell Ranges extend along the tropic as a series of parallel ridges culminating in Mount Heughlin (4800 feet). The main range is built of metamorphic rocks, but the southern units (Krichauff, Levi, etc.) are formed of folded Palaeozoic quartzites, etc. The Davenport Ranges (south-east of Tennant's Creek), rising about 1000 feet above the general level, are relics of a tableland dissected by the Frew, Gosse, and other rivers. In the extreme north of the Territory the Arnhem tableland is of much the same nature, but has not yet been properly explored. The well-known Barkly tableland in the north-east nowhere rises much above 1000 feet, and is merely the edge of the peneplain mentioned previously. The country as a whole is undulating and sparsely covered with timber. Eucalypts predominate in the wetter coastal regions, forming savannah-forest country or treeless savannahs, which are well-grassed in favourable years. In the interior and drier areas acacias are plentiful, especially the mulga. In the south, where they are more abundant, the saltbushes form a valuable herbage.

Hydrography.—The coast, except in the Gulf of Carpentaria, is much indented by inlets generally determined by Tertiary subsidence, which has drowned many river-mouths. It is little frequented, and there are practically no settlements except at Darwin itself.

The Victoria River, which enters the sea at the north-western corner of the Territory, penetrates farther into the Australian continent than any other known river on the north coast. Small craft can ascend it for 100 miles. The next important inlet is Anson Bay, where the Daly River enters the sea. It is usually navigable for 70 miles by vessels drawing six feet, but during the wet season the river is like a mountain torrent, and unnavigable. Port Darwin is an important harbour, a port of call for boats from Queensland to China, Singapore, Java, and India, and the terminus of cables to Java and to Singapore.

Two large islands (Melville and Bathurst) shut off Van Diemen's Gulf from the Timor Sea. The former, 75 miles long, is inhabited by a fine type of aboriginal. Many Indian buffaloes graze on the island. To the east of these islands is Coburg Peninsula, on which are the ruins of Port Essington; thence eastwards the coast is almost unvisited (save by trepang hunters) as far as the mouth of the Roper in the Gulf of Carpentaria. The aborigines are hostile, exploring parties through Arnhem Land have found no indications of valuable ores, and the district is not very encouraging from a pastoral point of view. Cape Arnhem, the north-east point, is just north of Caledon Bay. The sterile Groote Eylandt, about 36

miles long and 520 feet high near its centre, lies in the Gulf just north of the Roper entrance. The Roper River enters at the corner of the Gulf. It is a very fine stream, somewhat blocked by shallows at the mouth, but penetrable for 90 miles by vessels drawing 14 feet. The McArthur River enters the Gulf near Sir Edward Pellew's Islands; on one of these it is proposed to build a port, whence a railway will run to tap the Barkly region in the hinterland. Some 40 miles up the river is Borroloola, one of the chief settlements outside Darwin. The coast along all this portion of the Gulf is low, and the water shallow, indicating a general movement of elevation.

As in Western Australia, so in the Territory, there are several shallow inland basins. To the west of Powell's Creek (which lies on the low divide) is an indefinite area called Lake Woods, into which enter the intermittent creeks Newcastle Waters, Winnecke River, etc. On the eastern side Lake de Burgh receives the Creswell, Playford, Gosse, and Frew Rivers. Between the Macdonnells and the Musgrave Ranges to the south lies the large salt lake named Amadeus. Some doubt exists as to its level, which is probably about 1670 feet above sea-level. It receives no definite rivers, and is a mere expanse of salt 90 miles long and 15 wide. The Finke and other rivers running towards the NW. corner of Lake Eyre rise in the Macdonnells. They are a very important economic factor; they cut abruptly across the parallel ranges, excavating deep narrow gaps that contain numerous permanent rock-pools, and will lend themselves readily to dams in the future. The Palmer, the Hugh, and the Todd are the chief tributaries of the Finke. Only in heavy flood does the Finke reach the Macumba and enter Lake Eyre.

From north to south there is considerable variation in rainfall, ranging from 60 inches to six inches per annum at Charlotte Waters. It is entirely a summer rain, and this makes for a more uniform type of flora than the diversity in amount would suggest. Even in the north there are no rain-forests, while in the south (including the sand-ridge country) there are always numerous mulga trees. Next to the rainfall, the chief influence on vegetation is the varying composition of the soil. In the north the Cambrian limestone soils carry good feed and finer trees than do the Cambrian quartzites or Carboniferous sandstones. In the south the sandy formations are more useful than the clay-pan country that often alternates with them. On the whole the soils are rather sterile, and basic lavas—which do so much to enrich the soil in the east and south—are almost wanting. Thick coatings of laterite and travertine have been 'sweated out' by the hot sun, and cover the surface, as in most dry tropical countries.

The country has been opened up for 40 years, and its capabilities are now fairly well known. The most attractive portions (i.e. those containing natural permanent waters in the form of extensive waterholes, as on the upper Roper and Frew rivers) have been taken up many years since.

Population.—Of the four thousand people in the Territory, half are collected at Darwin and on the mining fields round Pine Creek. The other chief districts with their population are Barkly tableland (about 400), Alice Springs (about 400), Victoria River (about 200), and along the overland telegraph line (about 200). The remaining 1500 people are scattered over half a million square miles—probably the sparsest white population in the British Empire.

Products.—The most important industry is the grazing of *cattle,* which are chiefly carried on a belt that includes the Victoria River basin and the Barkly tableland. This belt receives about 20 inches per year, which accounts for extensive, well-grassed prairies between the arid mulga country on the south and the ranker vegetation of the north. The Victoria River district has about 300,000 cattle, and the Barkly tableland about 150,000. The chief stations on the tableland are Austral Downs, Avon Downs, Alexandra, Alroy, and Corella Downs. Along the overland line there are a few smaller stations, and about a dozen in the southern highland district, along the head-waters of the Finke River and its tributaries.

In 1914 there were about 600 *miners* in the Territory, of whom three-quarters were Chinese 'fossickers.' In 1921 there were only 340, about half of them white. Round Pine Creek are the Brock Creek gold-mines and the tin-mines of Mount Wells, Mount Todd, and Umbrawarra. Wolfram comes from Yenberrie and Wolfram Camp, and some copper is obtained on the Daly River. The whole industry is, however, languishing. At Tanami (near the western border) is a goldfield severely handicapped by distance and lack of permanent water. Arltunga near Alice Springs has produced much gold, and some mica occurs in the vicinity. Experiments connected with stock and agriculture are being carried out by the government at Darwin, on the Daly, and at Mataranka at the head of the Roper River.

The earliest industry was the collecting of trepang (bêche-de-mer) by the Malays. This animal (one of the starfish family) for 1921-2 yielded £2049. Tortoise-shell is also obtained in the coastal waters. Pearl-shell abounds, but the heavy tides render it a difficult product to win. Some 28 men are employed in the industry.

South Australia.—*Area*: 380,070 sq. m. (all temperate). *Rainfall*: Over 10 inches, 62,470 sq. m.; under 10 inches, 317,600 sq. m. *Population* (1921): 495,160 whites, 1609 aborigines. *Chief Towns* (1921): Adelaide (260,542), Port Pirie (9801), Mount Gambier (3969), Wallaroo (3308), Gawler (1775), Moonta (1335). *Stock* (1922-3): cattle, 425,811; sheep, 6,305,133. *Chief Products*: wheat (1922-3), 28,784,767 bushels; wine (1922-3), 8,653,579 gallons; gold (1922), 1000 fine oz.; iron ore (1922), 51,423 tons; copper (1922), 1185 tons; salt (1922), 48,657 tons. *Railways* (1921-2): 3487 miles. For statistics of stock, products, etc., not given here see separate articles on Horses, Sheep, etc.

Topography.—Although much smaller than the two regions already considered, this State exhibits greater diversity in its topography. In the west it is an important segment of the western peneplain. In the north-east is the inland depression of Lake Eyre, the normal shore-line of which is 39 feet below sea-level. In the centre and south is the Torrens Rift valley, flanked by that striking topographic unit the Flinders Range. In the south-east are low-lying plains beyond the lower Murray. The highest point is Mount Woodruffe (possibly 5000 feet) in the Musgrave Ranges, which run E. and W., far from any settlement, along the northern boundary of the State. They are broad residuals above the old peneplain. The country slopes very gently from them down to

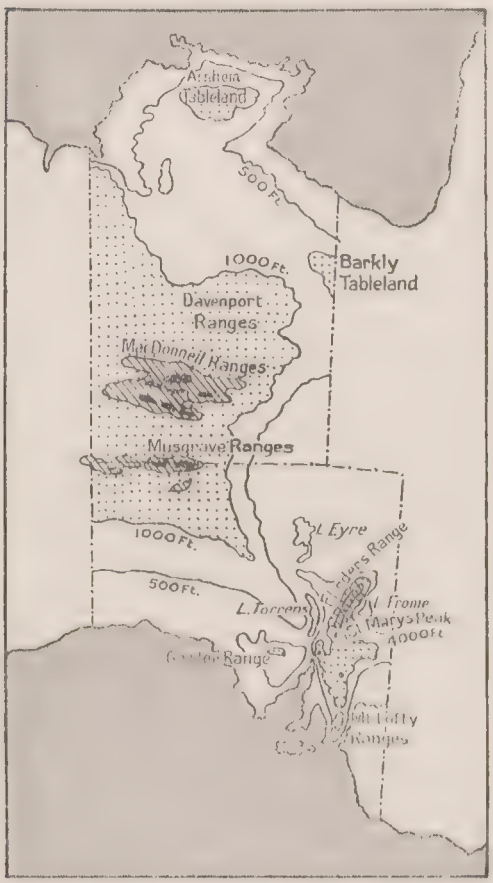
the coast, and not until the transcontinental railway is reached are there any habitations; but here, and also close to the coast along the telegraph line, are a few sheep-stations.

There are two other groups of highlands—the Gawler Range, granite bosses rising five or



six hundred feet above the surrounding country, and the Flinders Range. The latter runs almost N. and S.—i.e. across the trend of the Macdonnell, Musgrave, and Gawler ranges—for 400 miles, and rises almost to 4000 feet in St. Mary's Peak near Edieowie; Benbonyatha in the north and Mount Remarkable near Port Augusta are well over 3000 feet. A broad, low extension stretches towards Broken Hill, and south of this rises to 2835 feet in Mount Razorback near Kooringa. The southern portion, known as the Mount Lofty ranges (2334 feet), lies behind Adelaide.

The plains in the north-east and south-east are best considered in connection with the rivers.

Hydrography—Coasts.—The State has a much-indented coast-line, consequent on relatively recent subsidences of the crust. The Adelaide district, in fact, is still subject to seismic shocks of considerable intensity. Since almost all the population—as will appear later—is confined to the coastal regions, they are here described rather fully.

There are three broad divisions; the smooth coast of the Bight, the three peninsulas (Eyre, Yorke, and Fleurieu), and the smooth south-eastern coast. There are no landing-places in the cliff-bound coast from Eucla to Fowler Bay. At the head of the Bight the cliffs are lower than to the west, but westerly winds drive heavy seas against the lee shore to eastward. The small settlement of Port Eyre (Yatala) lies in the sheltered anchorage of Fowler Bay. Nuyts' Archipelago fringes the coast to the east. At the southern corner of Streaky Bay the township of Flinders has a jetty and light. On Eyre's Peninsula there are on the west Anxious Bay (Parkin) and Coffin's Bay (Wangary), and on the east an important harbour, Port Lincoln, which has been used as a naval training station. Port Lincoln is said to be the finest harbour in South Australia. Being a railway terminus, it collects wool and wheat from the Peninsula; there is a long jetty and a light, and steamers call regularly from Adelaide. The coast to the northward is low; Tumby Bay, and Cowell on Franklin Harbour, are the chief settlements until False Bay is reached. Here a railway to Iron Knob brings iron ore to the coast, where it is shipped across Spencer Gulf to Port Pirie. At the head of the gulf is Port Augusta, the terminus of the federal railway to Western Australia; it has fine wharfing accommodation and three jetties. Wheat, copper, wool, and hides are exported. To the north the gulf, much narrowed, extends somewhat indefinitely, and gradually merges into a salty swamp over 20 miles long.

Proceeding down the east coast of the Gulf, we pass notoworthy ports at Port Germein, Port Pirie, and Port Broughton. At Port Pirie are large smelting works, connected directly by rail without break of gauge to Broken Hill. Vessels drawing 20 feet can discharge here. Over 12,000 people live in the district, which grows much wheat. At the northern end of Yorke Peninsula are the copper towns of Wallaroo and Moonta. Both have large smelting works, and are connected with Adelaide by rail and steamer. The remainder of the peninsula is chiefly agricultural. It ends in Cape Spencer, off which a powerful light is situated on Althorpe Island.

St. Vincent Gulf lies between Yorke and Fleurieu peninsulas. It is bounded on the south by Kangaroo Island, and can be entered by the wide Investigator Strait from the south-west, or by Backstairs Passage from the south-east. There is little settlement along the south coast of Yorke Peninsula, but Edithburg is a small township just N. of Cape Troubridge. A light visible 15 miles is placed on Troubridge shoal. Low cliffs occur most of the way to the head of the gulf. There are small settlements at Stansbury, Port Vincent, Ardrossan, etc., chiefly exporting wool and wheat, and acting as watering-places for Adelaide. Port Wakefield at the head of the gulf is on the rail from Moonta to Adelaide. Wool and wheat are its chief interests. Low swampy coasts bring us to Port Gawler (of little importance), and then the entrance to Port Adelaide is reached. Here huge engineering works have produced a fine outer harbour, where ships of 18,500 tons can berth, as the depth of water throughout is 33 feet. The wharf, over half a mile long, is connected by rail with Adelaide. A sandy tongue of land (Lefevre's Peninsula) separates Port Adelaide (nine miles up the Torrens River) from the sea. Largs and Semaphore, on this tongue of land, have wharves projecting into Largs Bay. The capital is situated inland, some six miles from the coast and ten miles south-east of Largs Bay. Henley Beach, Glenelg, and Brighton are watering-places south of Largs

Bay. A low rocky coast leads south to the small port of Noarlunga at the mouth of the Onkaparinga River. Aldinga and Yankalilla are small settlements to the north of Cape Jervis.

Kangaroo Island is 80 miles long and 24 miles wide. It is for the most part low-lying, the summit (in the south-west) being only 700 feet. The settled area lies chiefly in the north-east, at Kingscote and Hog Bay. A telegraph runs to Cape Borda at the western end, where there is an important lighthouse and signal-station. The island is largely covered with are mallee, but much barley and wheat are grown in the north-east. Steamers from Port Adelaide call regularly at Kingscote.

Eastward of Cape Jervis extends a bold granite coast until the three small towns of Port Victor, Port Elliot and Goolwa are reached —the last an important port situated within the Murray mouth. Our largest river enters the sea by a narrow opening in the beach, across which the surf usually breaks heavily, so that it is only used by vessels of light draught. The mouth shifts eastward as the sand-dunes drift before the prevailing wind, and the bar is only about 10 feet below the surface at high tide. Within the mouth are three openings leading into Lake Alexandrina, 20 miles long and about 10 miles wide; a smaller expanse, Lake Albert, joins it on the south-east. South of the mouth extends for 90 miles an unbroken sandy coast, flanking the lagoons that form the Coorong. Lacepede Bay (with Kingston) forms its southern limit, from which a railway traverses wheat country to Naracoorte and the main line. At Cape Jaffa are a light and a signal station. Robe, Beachport, and Grey Town on Rivoli Bay, and Port MacDonnell (with a lighthouse on Cape Northumberland), are small ports in the extreme south-east.

Rivers and Lakes.—As a whole the State is poorly watered. The rivers fall into three groups —(1) those flowing into Lake Eyre; (2) those draining the Flinders Range; (3) the Murray. North-west of Lake Eyre are the Macumba (receiving the Finke, Stevenson and Alberg) and the Neales; all these, except the Finke, rise in the Musgrave and Everard ranges. Their channels are usually long stretches of white sand, apparently dry; but the occasional transverse rock-bars have water flowing over them, so that under the white sand also there must be water. Heavy downpours, of course, will produce a visible stream, which lasts until the natural absorption of the sandy bed can account for the whole inflow. The eastern side of Lake Eyre is a vast alluvial delta, into which flow the Diamantina and Cooper's Creek. Distributaries are numerous, the chief being the Strzelecki, which supplies the chain of lakes from Frome to Gregory. All these lakes are within a few feet of sea-level, and Lake Eyre is from 39 to 60 feet below it. The lake covers about 3700 square miles, and if filled up to sea-level would only be enlarged to 5000 square miles; the suggestion that great economic results would follow its connection by canal with the sea is a pure chimera. In 1921 Gerald Halligan skirted it by air-plane. In times of heavy rainfall many square miles of this country are flooded. Lake Torrens, 130 miles long, and Lake Gairdner, 90 miles long, are merely saline mud-flats of no economic importance.

None of the rivers draining the Flinders Range are of any size. The Frome runs for 150 miles NNW. into the southern end of Lake Eyre. Willochra Creek runs N. from Mount Remarkable to the south-eastern corner of Lake Torrens; it is about 80 miles long, but only flows throughout in flood-time. The Broughton, Wakefield, Light, Torrens, and Onkaparinga are similar but shorter streams along the western flank of the ranges. On the eastern side the Siccus (Pasmore), which enters Lake Frome, occupies what seems to be the bed of a large river which in pre-uplift days (before the Flinders Range developed) flowed south to the gulfs. The chief importance of these rivers is as water-suppliers. Thus reservoirs in the Torrens and Onkaparinga valleys supply Adelaide; those at Beetaloo and Bundaleer supply Wallaroo, Moonta, and 34 other neighbouring townships; that at Barossa (supplied from the South Para) furnishes water to 23 townships in the Gawler district.

The lower Murray runs for about 250 miles (including meanders, 500) through South Australia. Along this distance it receives no tributaries of note, but flows between high banks cut in the soft sediments of the old Tertiary sea, and makes several abrupt bends, notably at Morgan. Since railways have tapped the river-towns steamer traffic has greatly decreased; the river is, however, of increasing importance as regards irrigation. Thus Renmark (3000) is entirely supported by the dried fruit industry, which for the period 1911-21 averaged 40,619 cwt. of raisins and 54,698 cwt. of currants annually; the dried fruit pack for 1923 amounted to 2750 tons, including currants, 1000 tons; sultanas, 975 tons; lexias, 520 tons. Many small settlements fringe the river, e.g. Berri, Pyap, Moorook, Holder and Waikerie above Morgan. The rich swamp-lands below Mannum, when properly drained and cultivated, yield enormous crops.

Artesian Water.—South Australia is fairly well-favoured in this respect. The NE. quarter, where the rainfall is only five or six inches per year, includes a considerable portion of the Great Artesian Basin, whose boundary practically coincides with the railway from Marree to Oodnadatta. Mound springs, where the excess water overflows naturally, are common SW. of Lake Eyre. Coorie Creek (1370 feet deep, east of Lake Frome), Raspberry (416 feet, near Oodnadatta) and Dulkaninna (2226 feet, on the Diamantina) are bores with flows of 1,000,000 gallons per day, and most of the nine bores on the stock-route from Marree to Birdsville exceed 400,000 gallons per day. The south-eastern part of the State is part of the Murray River Tertiary basin, which is largely fed by water falling in the Wimmera district of Victoria. In these bores the water is sub-artesian, and does not rise to the surface; they are usually less than 300 feet deep, and the water is good, especially in the south. It is probable that the beautiful lakes associated with extinct volcanoes near Gambierton are supplied largely from this artesian basin.

The area near Millicent has been rendered much more fertile by a system of widespread drains, costing half a million sterling, which serve to remove excess ground-water from the extensive swamps, and so to convert them into valuable agricultural areas. The Eucla artesian basin has not furnished important supplies, though stock are watered from bores in the Nullarbor Plains. Small basins near Adelaide and Willochra have been extensively tapped.

Population.—The centralization of population in this State is striking; 52½ per cent of the whole people live in the capital city. By drawing isopleth contours for the State it can be

shown that the population has spread from Adelaide north and north-west, so that the next two isopleths include Kapunda and Port Pirie respectively; the next zone (4-8 per sq. m.) includes Port Augusta, Petersburg, Morgan, and the lower Murray. Of the same rank is the first outlying settlement, that of Mount Gambier in the far south. The next zone (1-2 per sq. m.) includes Port Lincoln and the wheat-lands round Pinnaroo. A belt along the coast to Fowler's Bay, including the other zones, defines the area known as 'the counties.' The rest of the State is not so subdivided, its population being only 4000 (or 1 person to each 75 sq. m.); it is obvious, therefore, that the economic importance of the State is largely confined to 'the counties.'

Products.—Sheep are much more important than cattle in this State, but are steadily decreasing in number, for there were twice as many in 1890 as in 1815. They occur most abundantly in the south-east round Gambierton, and between Port Pirie and Cape Jervis; these two small districts include nearly half the total. The next important zone includes the area along the Broken Hill railway; Eyre's Peninsula (NW. of Port Lincoln) is also important sheep country. Only about one-sixth of the total live beyond the counties in the purely pastoral region. In the north-western corner there are no stations, the outlying flocks being on the Alberga.

Cattle are relatively of small importance. All the other States except Tasmania have larger herds, and the number has not varied much since 1890. They are confined almost entirely to the Flinders highlands and to the Gambier district. Dairy herds occur chiefly in the Adelaide region (from Gawler southward) and round Mount Gambier. But among the copper towns, as also in Eyre's Peninsula, there are important dairying districts. Only a quarter of the cattle are grazed in the huge area beyond the counties, chiefly in the north-east and near the railway to Oodnadatta.

The State is pre-eminent in *wheat-growing*. It ranks third of the Australian States in total production, but produces twice as much per head as New South Wales (the leading State). The rainfall control is absolute. The extreme boundary of the wheat-growing area appears to be the 6-inch winter isohyet (April-October), which runs approximately parallel to the 10-inch annual isohyet and about 25 miles outside it. This limit is beyond Goyder's well-known line, which was based on the native flora, and was, indeed, within the 10-inch wheat-rainfall line. However, no wheat-crops of importance are grown north of the 10-inch annual rainfall line.

The five counties north of Adelaide are the chief producers, Wallaroo being perhaps the centre of the heavy wheat-crops. But almost all the area between Port Augusta and Wolseley on the Victorian border is devoted to wheat, as is the eastern coast of Eyre's Peninsula. The greatest development has taken place in the erstwhile useless mallee plains south of the Murray, round Pinnaroo. Many miles of railway lead from Tailem Bend to irrigation settlements such as Waikerie, Loxton, and Renmark, or through new wheat-centres like Karoonda, Alawoona, Parrakie, Pinnaroo, Gurrai, and Peebinga. In Eyre's Peninsula similar new lines lead from Port Lincoln northward through fresh wheat country to Darke's Peak and Kimba, and westward via Yeelanna and Minnipa to Ceduna, 269 miles away, on the coast at Denial Bay.

Eighty-four per cent of the *wine* comes from the counties of Adelaide and Light, i.e. the area south of Kooringa; Angaston, Tanunda, Clare, Lobethal, and Truro are centres of viticulture. Grapes are also grown at Renmark on the Murray and in the Gambier district. The hill-slopes of the southern Flinders Range and of Mount Lofty seem particularly suitable for this industry, receiving a total rainfall of about 20 inches, most of which falls in winter. These conditions closely resemble those obtaining in the Mediterranean countries that are the chief centres of the wine trade.

The State is poorly provided with *forests*, but the forestry department is doing good work to remedy this shortage. There is practically no timber industry, only 1,187,000 super feet being cut in 1922-3. The Mount Lofty ranges, with a 20-inch rainfall, are fairly well wooded with stringy-bark, blue gum, manna gum, and peppermint; the ubiquitous red gum is found in the valleys. Within the 15-inch isohyet the vegetation belongs to the 'Savannah forest' type, where grass replaces the bushy undergrowth of the better watered regions. The eucalypts grow farther apart, but on the whole belong to the same species.

Copper is the most important metal. Formerly the four mining-fields of Kapunda, Burra, Wallaroo, and Moonta easily placed South Australia at the head of the list in copper production, but the two first named are of little importance now. Wallaroo and Moonta have produced copper worth 13 millions sterling, and are still very important producers. Many smaller mines are scattered through the ancient rocks of the Flinders Range, perhaps the chief being at Blinman. *Gold* has never been of much importance. Barossa, 30 miles north of Adelaide, and Teetulpa on the Broken Hill line have yielded the most, but Tarcoola on the transcontinental railway is the chief field of late years. From Iron Knob, 40 miles SW. of Port Augusta, about 1,000,000 tons of *iron* ore have been shipped to Port Pirie as fluxes for the Broken Hill ores. In 1920 about half a million tons were sent to Newcastle, and smelted there at the Broken Hill Proprietary Co.'s works.

Near Edithburg on Yorke Peninsula is Lake Fowler, a shallow expanse from which half a million tons of crude *salt* have been scraped. At Lake Hart, 120 miles NW. of Port Augusta on the transcontinental line, there is another deposit of large extent.

The East-west Railway.—The transcontinental railway, which was completed in November 1917, runs from Kalgoorlie for 1060 miles to Port Augusta, and links Western Australia to the eastern States. The gauge is 4 feet 8½ inches, and to it in the end all other inter-State lines will be standardized. It serves an area of about 90,000 square miles, which may be considered favourable for pastoral development. Possibly the western portion will ultimately grow 'dry' wheats, for the rainfall (though below 10 inches) falls regularly in the vital months.

The region traversed comprises a higher western portion (extending about 160 miles E. of Kalgoorlie), which consists of ancient greenstones, granites, etc., and an area of Tertiary limestones, which extend at a level of about 500 feet most of the way to South Australia. Inferior water is obtainable here from bores. Near Tarcoola in South Australia mineralized rocks crop out again. Outlying sheep and cattle

stations are situated at Wilgena and Coondambo, while there may be a future for the salt deposits at Lake Hart. The chief asset, however, is the saving of time in communication with Western Australia and Europe; the railway is also important from a military point of view.

QUEENSLAND.—*Area*: 670,500 sq. m. (359,000 tropical; 311,500 temperate). *Rainfall*: all above 10 inches, except 91,012 sq. m. almost all in temperate portion). *Population* (1921): 755,972 whites, 12,614 aborigines. *Chief Towns* (1921): Brisbane (217,714), Rockhampton (24,168), Townsville (21,353), Toowoomba (20,676), Ipswich (20,517), Maryborough (10,629), Charters Towers (9489), Bundaberg (9276), Cairns (7464), Mount Morgan (7220), Gympie (6537), Mackay (6313), Warwick (6091). *Stock* (1922): horses, 713,015; cattle, 6,955,463; sheep, 17,641,071. *Chief Products*: wheat 1922-3), 1,877,836 bushels; wool (1922), 134,971,150 lb.; maize (1922-3), 3,217,848 bushels; sugar (1922-3), 287,785 tons; cotton, unginned, (1922-3), 3,956,635 lb.; bananas (1922-3), 1,618,848 bushels; butter (1922), 53,785,599 lb.; cheese (1922), 10,560,316 lb.; milk (1922), 134,031,830 gallons; timber (1922) 126,088,000 super feet; pearls and pearl-shell (1922), over £125,000 in value; gold (1922), 80,584 fine oz.; silver (1922), 273,036 fine oz.; copper (1922), 5104 tons; tin (1922), 1094 tons; coal (1922), 958,519 tons. *Railways* (1921-2): 7064 miles. For statistics of stock, products, etc., not given here see separate articles on HORSES, SHEEP, etc.

Topography.—In this State we first meet with typical east-coast topography; the highlands are situated along the littoral, and the lowland plains are found in the west. In the physiographic section it will be shown that a great portion of eastern Australia has foundered beneath the Pacific, and the present coast-line is not far removed from the old divide. Speaking generally, the eastern plains are small, bordering the lower courses of the chief rivers; a belt of highlands often rises abruptly from the sea, and slopes gradually to the west. From Cape York to the South Australian border there is a great lowland area; the Gulf of Carpentaria is the drowned western portion of this lowland, and all the western side of the Cape York Peninsula is very low. An inlier of ancient rocks near Camooweal is connected with the highland region by the Kynuna uplands, but in a direct line from Cape York to Melbourne there is practically nothing above 1000 feet except three miles at the Kilmore gap in Victoria.

The most striking feature in Queensland topography is the Atherton plateau in latitude 18° S. This is a triangular area of about 12,000 square miles, all over 2000 feet, and is bounded on the north-east by the Bellenden Ker Range, which rises to 5438 feet in Mount Bartle Frere. Only three other small districts rise above the 2000-ft. contour, so that Queensland is generally of very moderate elevation. There is a crescent of high land round the Bowen River behind Mackay, which includes the Clarke and Leichhardt ranges; the Buckland tableland, south of Springsure, is the second; and the Darling Downs (an offshoot from the Macpherson Range) form the third. Mount Roberts and Wilson's Peak, near the border of New South Wales, are 4000 feet high. All the rest of Queensland, including the numberless mountain ranges listed in school geographies, is (except for isolated peaks) below 2000 feet. This is true for the so-called 'main dividing range,' which is really composed of a series of basalt flows and minor warps or peneplain residuals. [Some day atlas-makers will realize that the 1000-ft. contour is infinitely preferable to the 'herring-bone' hachure, and then our main divide will be adequately represented.]

The various tributary 'ranges' are also largely residuals, left as divides by river-erosion. This is indicated by the prevalence of the nomenclature 'downs'—e.g. Peak Downs, east of Clermont; but fragments of an older series of granite and allied ranges occur along the coast—e.g. the D'Aguilar Range and the Glasshouse Mountains near Brisbane, the Dawes Range behind Bundaberg, the Normanby Range south of Broad Sound, and Mount Elliot (4000 feet) near Townsville. In the Peninsula are a few isolated highlands of little importance, all fringing the east coast. Elevated divides (rather than ranges) separate the western rivers. Thus the Grey Range separates the Bulloo from Cooper's Creek, and the Beal Range lies between that river and the Diamantina; but they are only important by contrast with the wide expanse of low-lying plains. The Selwyn highlands, south of Cloncurry, rise well above 1000 feet, and merge into the Barkly tableland on the borders of the Northern Territory.

Hydrography—Coasts.—The south coast of the Gulf of Carpentaria is very low and entirely fringed by mangroves. Approach is difficult, as the waters are very shallow. The Wellesley Islands rise to about 300 feet; Mornington Isle is 35 miles long. On Sweers Island was the now vanished settlement of Carnarvon. The Nicholson, Albert, and Leichhardt rivers discharge at the southern end; Burketown lies some 40 miles up the Albert. At the south-eastern corner are the mouths of the Flinders and Norman rivers. The latter river has a pilot station (Karumba) at its mouth, whence

small boats can reach Normanton, 45 miles inland.

The eastern shore of the Gulf is low, and formed of alluvial brought down by numerous rivers. There are a few cattle-stations on the higher land away from the coast, and mission stations near the mouth of the Mitchell, Archer, and Batavia rivers. The last is a fine stream, navigable for boats for 36 miles. The Gulf as a whole is very shallow—nowhere more than 43 fathoms.

Torres Straits are filled with small islands and coral-reefs. Prince of Wales Island, the largest, is 11 miles across. Thursday Island, much more important, is 374 feet high and about 1½ miles long; Port Kennedy on the south side is a port of call for vessels from Brisbane to London, India, Hong Kong, and Japan. Stocks of coal are held on it, and it is also the centre of the east-coast pearling trade. Cape York is a prominent landmark, a hill on it rising to 400 feet. Near the small settlement of Somerset, just to the east, the *Quetta* was wrecked with great loss of life in 1890. Apart from three lights (at Temple Bay, Cape Sidmouth, and Cape Melville) there is little of interest north of Cooktown. Two large bays (Shelburne and Princess Charlotte) occupy basins where the coast truncates the meridional ridges. At Cape Melville the continental shelf bearing the great coral-reef barrier is narrowest (12 miles), and a little south of it is Cook Passage, where vessels running between Cooktown and New Guinea traverse the reef. Southwards begins a series of remarkable capes, all really high and rocky islands, separated from the hinterland formerly by water, now by low plains—Capes Flattery, Bedford, Archer, Tribulation, and Grafton. Peterbotte is an isolated peak (3468 feet) behind Cape Tribulation.

Cooktown, the first settlement on this coast, ranks as the tenth port of the State. It has about 900 inhabitants, and a railway runs inland 67 miles to Laura near the Palmer goldfields. Here in 1770 Cook carcened his ship in the Endeavour River, after being wrecked on a coral-reef 30 miles to the south. Cairns, about 100 miles south, is the fifth port in the State as regards the number of ships entering it. Behind it the Barron River has cut a remarkable gorge in the scarp of the Atherton tableland, and the falls (600 feet) are the finest in Australia. The tableland is served by a railway from this port, and another connects it with Townsville. The heaviest rainfall in Australia (165 inches) falls at Harvey Creek, 30 miles south of Cairns. The whole coast south of Cooktown is mountainous. The grain of the land runs north and south, and the oblique coast, cutting across this, has produced a succession of rocky headlands and long, narrow bays. Innisfail, Cardwell, and Halifax, which lie at the foot of the great scarp, are centres of sugar districts. Hinchinbrook Island (3650 feet), separated from the mainland by a navigable channel about 20 miles long, is comparable with the land-tied islands noted previously, and with those bordering Whitsunday Passage farther south.

Townsville, the third town and second port in the State, lies on Cleveland Bay behind Magnetic Island. It is the terminus of a railway that serves a large part of northern Queensland, running inland to Cloncurry and Winton. Its exports total some two millions sterling. To the south the coast is lower; the Burdekin River, which enters Upstart Bay by several mouths, is only navigable for small boats and is infested with crocodiles. Ayr on the delta is connected by the coastal railway with Townsville to the north and Bowen and Proserpine to the south. Bowen, the next port (sixth in rank), serves an important pastoral region and a valuable coal-field on the Bowen River. Whitsunday Island, separated from the mainland by one of the most picturesque passages (30 miles long) along the Australian coast, lies halfway between Bowen and Mackay. Off the latter is a powerful light on Flat Top Island. Mackay is the centre of an important sugar district, and does a large coastal trade. Broad Sound (with St. Lawrence) and Shoalwater Bay are two north-pointing openings due to the drowning of the grain of the land. Almost on the tropic is Rockhampton, 35 miles up the Fitzroy, the second town and third port in the State, and the terminus of the central railway, which runs to Longreach and Blackall in important sheep country. The coastal railway which connects it with Brisbane is extended past it northwards to Townsville and Cairns. Copper, gold and coal, mines occur in the hinterland.

Gladstone and Bundaberg are the next two ports. Off the latter is Lady Elliot Island, the most southern coral islet of the Barrier Reef. Great Sandy Isle, 68 miles long, rises to 800 feet; a powerful lighthouse is placed on its northern extremity. Maryborough is 15 miles up the Mary River, which empties into Hervey Bay behind Great Sandy Island. It has a considerable coastal trade. Thence there are no important inlets or ports until Moreton Bay is reached, which is sheltered from the Pacific by Moreton and Stradbroke islands, each about 20 miles long. Brisbane, the capital city of the State, is situated 13 miles up the Brisbane River. It is by far the largest town in the State; 28 per cent of the whole population is concentrated here—a much smaller proportion than in the other large capitals. Southport is a watering-place on the coast to the south, not far from Point Danger, the boundary of the State.

Rivers.—Queensland is perhaps the best watered of all the States except Tasmania, because so large a portion of it lies in the region of fairly uniform rain. Few of its rivers, however, are of any importance for navigation. As we have seen, the grain of the land runs north and south, so that the coastal streams in general have to cross these ranges near their mouths. The Fitzroy, perhaps the principal river, is about 500 miles long, and has many large tributaries such as the Dawson, Mackenzie, and Isaacs, but above Rockhampton navigation is practically non-existent. The Burdekin, about 400 miles long, has a similar zig-zag course determined by the coastal ranges. The Suttor, Belyando, and Bowen are its principal tributaries. Both the Fitzroy and Burdekin appear originally to have been west-flowing rivers, but have been captured by coastal streams. The Brisbane River, about 200 miles long, rises on the Darling Downs and flows through a rich dairying and agricultural district. Coal-barges float down from Ipswich to the capital. The Mary and Burnett are smaller rivers between the Fitzroy and Brisbane. North of the Burdekin the highlands have been so abruptly truncated by the faulted coast that there is no room for large coastal rivers. Indeed, the Mitchell, which rises close to the Barron Falls on the east coast, flows thence westward to the Gulf.

The chief rivers flowing into the Gulf have been mentioned. Several important ones flow

south into Lake Eyre or the Darling. The principal tributary of the Darling is the Condamine, which drains the western slopes of the Darling Downs, then, with the Maranoa, forms the Balonne, and flows through rich pastoral country to split again into the Culgoa and Narran. The Warrego and Paroo, farther west, occasionally reach the Darling, but are usually lost in the vast alluvial beds of north-western New South Wales. The Barcoo and Thomson unite to form Cooper's Creek, and often send down huge floods into Lake Eyre. The Diamantina and Eyre, whose head-waters are in or near the Selwyn highlands, similarly join to form the Warburton, and more rarely reach Lake Eyre. All these inland rivers vary greatly in their flow, and for long periods are mere strings of waterholes; but in flood-time their lower waters may spread out 20 miles or more over the flat western plains.

Artesian Basin.—Queensland is specially favoured in that 56 per cent of the State (including her driest region) forms part of the chief artesian basin in the world. A line joining Normanton to Warwick roughly indicates the eastern boundary, and the whole region westwards, except the inlier of older rocks west of Cloncurry, forms part of the basin. The 1287 flowing bores vary greatly in depth and supply; the deepest are in the north centre of the basin, as at Bimerah, 100 miles SW. of Longreach, where the bore goes down 5045 feet (a bore 40 miles W. of Blackall, in the same area, goes down 7009 feet); many others over 4000 feet deep occur between Hughenden and Windorah. The temperature is often very high, as at Eldershe near Winton (200° F.). The largest flow comes from Millungera (100 miles NE. of Cloncurry), where it is said to total about five million gallons daily, and there are 152 bores giving over one million gallons each. The rapid increase in stock in western Queensland is largely to be credited to this supply, which amounts to 299 million gallons daily.

Population.—For the whole State the population is over one person per square mile, but the great majority of the inhabitants are clustered along the central and southern coast-line. Several regions merit special consideration. The capital and the lower Brisbane valley (including the Ipswich coal-field) are naturally the most closely settled. Apart from the elevated Downs country, they have naturally the coolest climate in the State. Rockhampton and its neighbour Mount Morgan form the second 'cluster,' which has similarly grown up at an important railway terminus supported by a valuable mining-field. Similar centres on a small scale occur at Gympie, Maryborough, Bundaberg, and Mackay. Townsville and Charters Towers form a somewhat isolated community in the north, and the Chillagoe mines, coupled with the rich agricultural district of the Atherton tableland, have led to a large settlement of whites within 18° of the Equator. Along the southern railway fairly close settlement has spread as far as Roma and Mitchell, with prosperous farming communities on the high land round Toowoomba.

North and west of a line joining Cooktown to Burketown and thence to Cunnamulla there is hardly any settlement. Probably only 15,000 people live in this area of approximately 190,000 square miles, or 1 to every 13 square miles. Some 3000 more are engaged in fishing and trading in the far north, with Thursday Island as a centre.

Products.—The most important industries are connected with *cattle;* Queensland contains about half of the Australian total. The chief cattle areas are south of the Gulf, round Townsville and Rockhampton, and in the southern corner. It is obvious, therefore, that they keep to the hotter, rougher and wetter regions, leaving the dry, open central plains for sheep. Dairying is making rapid progress, 563,683 of the cattle belonging to dairy herds. The south-eastern corner is naturally the most important in this respect, and contains nearly half the total. Maroochy, north of Brisbane, and Beaudesert to the south are especially concerned. Another quarter graze in the Wide Bay district, where Gympie is an important centre, and about the same number on the Darling Downs. Only four per cent are distributed elsewhere in Queensland.

The distribution of *sheep* in the State is very definitely arranged in a series of zones about Longreach. Sixty per cent are pastured in the province of Mitchell (round Longreach), Warrego (S.) and Maranoa (SE.). The next zone includes Burke (N.), Gregory (W.) and Darling Downs (SE.). The inland portions of the central and western railways serve the chief sheep regions, which are clustered round Longreach, Charleville, Cloncurry, Hughenden, Barcaldine, Cunnamulla, and St. George. The great majority are grazed on the grass-land and open forest country lying between the 10-inch and 30-inch isohyets. In good years the south-western corners of the State are occupied, but in bad droughts these stations are sometimes temporarily abandoned. With greater facilities for watering by means of dams and bores, and with better railway transport, sheep will be grazed in much greater numbers in the west and north-west.

Since the comparatively recent beds that form the Great Artesian Basin build up almost the whole of central and western Queensland, its *auriferous* areas are confined to the ancient rocks of the eastern highlands and of the Cloncurry inlier. The chief fields are near the east coast. Mount Morgan (near Rockhampton) was in 1922 by far the largest producer; Gympie was a bad second, and Charters Towers in the north a worse third. Two smaller fields at Etheridge and Croydon are situated on the edge of the artesian basin south-east of the Gulf; the Etheridge field (round Georgetown) is connected with the Cairns railway; the Croydon field is linked to Normanton on the Gulf.

Cloncurry and Mount Morgan are by far the chief producers of *copper.* In 1922 out of a total yield of 4984 tons Mount Morgan produced 4483 tons; the Cloncurry yield decreased from 7640 tons in 1920 to 325 tons in 1922. Etheridge, Herberton and Chillagoe are less important copper-fields.

Over 60 per cent of Queensland *coal* comes from the Ipswich seams. These are older than the artesian beds, and dip under their eastern edge. The Aberdare seam, in places 11 feet thick, is the chief. An immense seam of much older formation occurs at Blair Athol near Clermont; in 1922 104,141 tons were hewn here. The Atherton tableland, in addition to its gold and other metals, has a coal-field at Mount Mulligan; the output is small, but of great value in that isolated locality. The Dawson Valley field is being opened up at Baralaba.

In 1922, 1098 tons of *tin* were produced; Herberton contributed over half, and Kangaroo Hills was second in importance. Near Cooktown in the north and Stanthorpe in the south there

are valuable tin deposits. Three rarer metals—*molybdenum, wolfram,* and *bismuth*—are found in considerable quantities, especially in the Chillagoe district. *Sapphires* are found at Anakie (south of Clermont); over £35,000 worth were obtained there in 1922. Precious *opal* is the only mineral deposit in the artesian basin, a belt of opal-fields running across the west of the State from Kynuna through Opalton to Cunnamulla.

Forests of commercial value are confined to the eastern coast, where the annual rainfall is about 25 inches and fairly uniform. Two classes of forest occur; the 'vine scrubs,' the tropical rain-forest of the botanist, knotted together by vines and lianas, which contain many softwood timbers allied to Malayan types; and the valuable hardwood forests, containing various eucalypts like those in the temperate rain-forests of the south-east. Pines (*Agathis* and *Araucaria*), together with cedar, silky oak, native maple, native beech, etc., are the chief softwood timbers. They occur along the Atherton scarp from Cooktown nearly to Townsville, and smaller patches are found near Bowen and Mackay. From Gladstone southwards the two classes of forest are much mixed. There is a thick forest of this type between Gympie and the Darling Downs, and another along the Macpherson Range. Eucalypt forests are also scattered. There is a belt just along the inner edge of the vine scrubs behind Cairns; Clermont and the western side of the Dawson basin have good forests; and all the south-eastern corner, especially the Darling Downs and south coast region, has a plentiful supply of eucalypts. In other parts of the State eucalypts, though widespread, are for the most part short and poor in form.

Wheats grown in the southern States spread into the south-eastern corner of Queensland. The total crop is relatively small, for the centre of production is Warwick, almost on the border. Nanango (north of Toowoomba) is about the northern limit, while Mitchell and Roma are at the western boundary. It is probable that Indian types can be grown successfully on the tropic near Emerald and Tambo. The present crop grows where 10 to 15 inches of winter rain fall. The *maize* crop, as it is better suited to warm climates, is three times as large as the wheat; it is grown chiefly in the south-east, especially round Nanango and in the upper Brisbane valley. The Maryborough and Burnett valleys are also very productive. One of the chief centres is far to the north at Herberton on the Atherton tableland, but it is grown in small quantities all along the coast. *Bananas* are an important crop in several districts, notably near Brisbane and Maroochy on the south coast, and at Mourilyan and Cairns on the north coast.

For many years the *sugar* crop has been worth over a million pounds annually, the greatest amount of sugar (307,714 tons) being obtained in 1917-8. The cane is confined entirely to the well-watered coastal alluvials, where the rainfall is in general over 60 inches a year. Mackay grows one quarter of the whole; Cairns, with the neighbouring districts of Ingham and Mourilyan, is even more important than Mackay; Bundaberg and Childers nearly account for another quarter—here the rainfall is about 40 inches per year. Proserpine and Ayr (near Bowen) and Port Douglas (near Cairns) are less important producers. Most of the coastal towns (as also Nanango and Kilkivan, inland) grow some cane, but their total does not bulk largely.

In 1922, 1040 men and 129 small vessels were engaged in the pearl-shell and bêche-de-mer (trepang) industries, with headquarters at Thursday Island. Pearls are found in the shallow waters of Torres Straits, and along the northern coral-reefs of the Great Barrier. The trepang occurs here also; in 1922 it was obtained to the value of £63,630, most of which was smoked and exported as a delicacy to China.

NEW SOUTH WALES.—*Area*: 310,372 sq.m. all in temperate zone. *Rainfall*: all over 10 inches, except 45,000 sq. m. *Population* (1921): 2,100,371 whites, 1597 aborigines. *Chief Towns* (1921): Sydney (926,400), Newcastle (84,372), Cessnock (30,215), Broken Hill (26,337), Parramatta (14,594), Goulburn (12,715), Maitland (12,008), Bathurst (9440), Lismore (8700), Wagga (7679), Orange (7398), Tamworth (7264). *Stock* (1924): horses, 498,194; cattle, 2,625,668; sheep, 37,387,895. *Chief Products*: wool (1922-3) 293,571,000 lb.; wheat (1922-3), 28,660,824 bushels; maize (1922-3), 3,287,500 bushels; potatoes (1922-3), 35,694 tons; sugar (1922-3), 18,580 tons; wine (1922-3), 771,206 gallons; butter (1922-3), 73,705,349 lb.; cheese (1922-3), 5,198,905 lb.; milk (1922-3), 226,863,925 gallons; timber (1922-3), 147,108,000 super feet; gold (1922), 25,222 fine oz.; silver (1922), 749,904 fine oz.; tin (1922), 1144 tons; zinc (1922), 363,681 tons; iron (1922), 54,856 tons; coal (1922), 10,183,133 tons. *Railways* (1921-2): 5475 miles. For statistics of stock, products, etc., not given here see separate articles on HORSES, SHEEP, ETC.

Topography.—In New South Wales, as in most States, we have to deal with peneplains and dissected plateaux, not with ridge-like ranges. The 'Great Dividing Range' is a misleading term, which should be replaced by the term 'Great Divide.'

The topography resembles that of Queensland—the highland area close to the coast, with a steep slope to the east and a gradual slope to the west, the latter merging into central lowlands built up of alluvial. An inlier of very ancient rocks round Broken Hill in the extreme west recalls the Camooweal and Cloncurry inlier in Queensland. The highlands are, however, on a much grander scale than in the northern State; there are large areas over 3000 feet—indeed, New South Wales contains three out of the four considerable plateaux in Australia, the fourth being in Victoria.

The largest area of highland in Australia is the New England plateau in the north-east of New South Wales, an irregular area about 200

miles long by 90 miles wide, all over 3000 feet, and comprising about 9000 sq.m. It is largely a granite plateau of fairly uniform level, but rises to higher levels both north and south. It is absurd to mark this large area as a narrow range, but most maps (even the official Commonwealth map) contain the absurdity. Three bosses between Armidale and Tenterfield (Ben Lomond, Capoompeta, and Chandler's Peak) rise above 5000 feet, and an important spur (Snowy Mountain) extends nearly to the east coast at Bellingen. The southern area, between the anning and Peel rivers, rises to 4000 feet. Outlying portions of the plateau are Sea View and Mount Royal, both over 3000 feet. The scarp on the east is very abrupt, espcially where it is cut by the gorges of the Macleay, and possibly represents a great fault-plane. The northern rim of the plateau is also higher than the general level, forms the Macpherson Range along the border, and rises to 4060 feet in Mount Lindesay. To the west of the plateau, separated from it by a series of folded sediments probably lying in fault-blocks, are two groups of ancient volcanic mountains—the Nandewars near Narrabri, which rise to 4000 feet, and somewhat to the south-west the Warrumbungle Range, of lower elevation, with Mount Exmouth (3000 feet); the latter is connected with the New England plateau by a lower basalt range, the Liverpool Range. Immediately south of the Liverpool Range, near Cassilis, occurs a striking break in the divide, the heads of the west-flowing Talbragar River and of the Goulburn, which flows in a deeper basin eastwards, almost meeting at a height of about 1500 feet. The greater softness of the coal-basin strata has in part enabled the Goulburn to cut back and capture various portions of the western drainage. This Cassilis 'geocol' or Gate is the chief gap in the divide between Roma in Queensland and Kilmore in Victoria—a distance of 1100 miles. Yet it is not yet traversed by railways, which have been built up the steep Blue Mountains south of it and up the New England plateau to the north in defiance of physiographic control.

The main central plateau is an elevated peneplain of heterogeneous composition, which rises to 4460 feet in Mount Bindo, near the Jenolan caves. It has a total area over 3000 feet of about 4000 square miles. Its northern portion (mainly 2000 to 3000 feet high) is a barren tract of sandstone intersected by deep gorges such as the Grose, Kanimbla and Capertee valleys. Apart from the tourist resorts along the western line, and a few fruit-farms on the basalt areas, this region is still one of the least occupied in the State. Westwards the plateau extends to the volcanic knobs of the Canoblas, and the slope is (as usual) quite gradual; on the east is the well-known Blue Mountains monocline, one of the finest later folds in the earth's crust. The effect of this fold—which has buckled the crust through several thousand feet—is described under PHYSIOGRAPHY.

The Lake George Gate is a gap in the Divide leading from the Wollondilly basin on the east to the Murrumbidgee basin on the west. The actual divide bifurcates round Lake George, where a portion of the crust has sunk down and formed an isolated basin. To the south is the Monaro tableland, which consists of a very elevated western portion, containing Kosciusko (7328 feet), the highest mountain in Australia; an eastern portion rising to 5300 feet in Tindery; and a lower longitudinal valley, occupied by the Murrumbidgee and Snowy rivers, between the two. The structure of Monaro depends on several fault-blocks which are discussed under PHYSIOGRAPHY. The two high massifs (about 3000 feet) total about 7000 square miles, and a considerable portion of the intermediate valley is little below the 3000-ft. level. For a few miles round Kosciusko, especially near Blue Lake, there is ample evidence of an ice age that capped the plateau in comparatively recent geological time. Mounts Townsend (7236 feet), Twynam (7200), Bimberi (6264) and Coree (4657) are dominant knobs in the Kosciusko massif; the two latter bound the Federal Territory west of Canberra. Eastwards the plateau is abruptly truncated by the coast, so that there is a rapid fall of 3000 feet on the road from Nimmitabel to Bega.

About three-quarters of New South Wales consists of lowland plains rising from 140 feet (at Wentworth) to the 1000-ft. contour. West of the highland region already briefly described only one small area near Broken Hill (the so-called Barrier Range, about 100 miles long) rises above 1000 feet. But connecting this ancient metalliferous area with the highlands is a broad, low, typical peneplain, called the Cobar peneplain. It has a general level of about 700 feet—little above that of the alluvials to north, west and south—but consists of ancient metalliferous rocks containing large deposits of gold and copper. Elsewhere the western plains are composed of deep recent deposits, carried seaward by the Murray and its tributaries. The land is remarkably level in the south-west. The river-plain is seamed with distributaries and anabranches, which are discussed below.

Hydrography—Coasts.—This State's coastline is the simplest in Australia. It extends for 700 miles almost as a straight line, except for a slight angle near Port Stephens. The coast as a whole is determined by late subsidences; hence the numerous drowned valleys, the steep scarps (so-called 'coastal ranges'), and the short, steep courses of most of the rivers. There are only three small but important coastal plains; the lower Clarence basin round Grafton, the Hunter valley, and the Sydney region east of the Hawkesbury River.

The State's northern boundary is at Point Danger, where a rocky spit renders navigation dangerous. Tweed River lies just to the south. Cape Byron, the most eastern point on the continent, carries a light visible 26 miles. Byron Bay is the outlet for the Lismore and Murwillumbah districts, with which it is connected by rail. The Richmond River, which enters the sea at Ballina, is navigable by small vessels for 70 miles; Lismore, at the head of navigation, is an important centre for sugar, dairy-farms and timber. The next estuary to the south is that of the Clarence River, much more important and 240 miles long. Grafton lies some 40 miles up, and vessels of considerable tonnage can reach it, while launches go 35 miles higher. Proceeding southwards, the New England massif approaches the coast, and near Coff's Harbour an outlier, Bellinger Peak (1350 feet), is prominent. The Macleay River enters the sea south of Nambucca; Kempsey, about 25 miles up, is an important town with a small dock. Smoky Cape, with an important light, is just south of the estuary. Port Macquarie at the mouth of the Hastings River and Taree on the Manning are two small river-towns. Most of these river-towns, as far north as South Grafton on the Clarence, are now connected by rail with Newcastle, and the line will soon be connected by a

bridge with that from Grafton to the Tweed and so with the coastal lines of Queensland.

A salient point on the coast is Sugarloaf or Seal Rocks Point, where there is a light visible for 22 miles; south of it the coast trends more to the west. At Port Stephens it is designed to make a naval port. This inlet, about 11 miles long, receives the Karuah and Myall rivers; bold headlands flank the entrance. Thirty miles south is Port Hunter, the outlet of the Hunter River. Newcastle, the second town of the State, situated on the southern shore of the estuary, is one of the chief ports in Australia, and by far the most important coaling station. Small steamers ply to Morpeth, 40 miles up the winding river. South of Newcastle are several coal-mines, with jetties from which ships are loaded directly, as at Catherine Hill Bay and Lake Macquarie. Drowned estuaries, converted into lagoons by sand-bars, occur at Tuggerah and southwards. Broken Bay is an extensive and picturesque opening where the Hawkesbury enters the sea. Barranjuey Head carries a light visible 15 miles. The river is blocked for large vessels by the railway bridge, but smaller boats can navigate it for 70 miles.

Port Jackson owes much of its pre-eminence to its physiography. It is a drowned steep-walled valley, whose ancient head-waters have probably been cut off by the Nepean River. Hence the waters of the harbour are deep, and require little or no dredging, since mere creeks like the Parramatta 'River' carry down no silt. The Heads are a little over one mile apart. The saltwater portion of the Parramatta River, which is the main branch, and extends 20 miles from the Heads, receives the Lane Cove River and Middle Harbour, each about eight miles long. The city of Sydney is built round and to the south of Circular Quay (seven miles up the harbour) where for many years the mail steamers berthed. Inlets on the southern shore east and west of the Quay have been lined with wharves and berths capable of accommodating vessels up to 40ft. draught.

The suburbs of Sydney stretch for many miles along both shores of the main inlet, north to Middle Harbour and south to George's River. Botany Bay, 12 miles south, is a somewhat larger and much shallower inlet due to the drowning of a plain, and is famous as the first landing-place of the English discoverers. It receives two small streams, Cook's and George's rivers. A few miles south is Port Hacking, another picturesque drowned river. Beyond it coal again outcrops on the coast, and there are several small coal-ports (Bulli, Clifton, Bellambi); but the coast is very open, and important works have been erected to facilitate the loading of coal, etc., at Wollongong and Port Kembla. Kiama is a small town noted for its road-metal quarries and for dairy produce. A little south is the delta of the Shoalhaven River; at its apex is situated Nowra, a town communicating by rail and steamer with Sydney, which marks the southern end of the picturesque Illawarra coast. The Shoalhaven mouth is blocked, and navigation proceeds through a canal to Crookhaven, five miles south.

Jervis Bay, the most striking inlet on the map, is enclosed by two bold headlands that terminate in capes projecting eight miles beyond the general coast-line. The Commonwealth's Naval college has been established on its southern shore, where there will some day be the terminus of a railway from Canberra, and the federal port. For about 160 miles farther south there is a flourishing dairy region, with important mineral deposits. The coast is steep, being the truncated edge of the Monaro plateau. Ulladulla, Moruya, Bega, and Eden are the chief townships, the latter (on Twofold Bay) being also a whaling station. The next promontory is Green Cape, with an important light, and 20 miles to the south a cairn on a low headland marks Cape Howe on the boundary of Victoria.

Rivers.—Except in the far west, the State is fairly well watered. All the inland rivers belong to the Murray system, and there is good reason to believe that many of the coastal streams are disjointed fragments of the same system. There are four main streams, the Murray and its three tributaries the Darling, Murrumbidgee, and Lachlan. The Murray runs for 1200 miles along the Victorian boundary. Of these about 900 (i.e. west of Albury) are navigable, though steamers usually run only to Echuca; Corowa, Swan Hill, Euston, and Wentworth are also important river-towns. The Riverina (the lowland between the lower Lachlan, Murrumbidgee and Murray) is crossed by numerous distributaries, anabranches, and billabongs. The flood-plain is extraordinarily level, and minor channels, such as the Moulamein, Edward, and Wakool, often anastomose. In 1914, for the first time on record, the Murray ceased temporarily to run; this was in part due to the increased demand for irrigation. A dam with a storage capacity of over 1,000,000 acre-feet is being constructed a little above Albury (see IRRIGATION).

The Murrumbidgee is entirely in New South Wales. It is about 1000 miles long, and rises near Kiandra in the Alps (its upper waters having been captured from the Snowy River), flows through the Federal Territory (Canberra is on its tributary the Molonglo) and is dammed at Burrinjuck, where it has cut a deep gorge. This reservoir, one of the largest in the world, covers 12,740 acres. The stored water, when released, runs down the river-bed to Berembed near Narrandera; here a diversion weir sends it into canals that supply the irrigation settlements to the north-west. The river is navigable for small steamers to Narrandera, but here as elsewhere the formerly river-borne trade is being captured by the less intermittent railway service.

The Lachlan is much less important, though about 800 miles long. It rises near Lake George and flows in a generally westward direction. Near Hillston it gives off a distributary (the Willandra Billabong), which in high floods may reach the Murray at Euston. The lower Lachlan in dry seasons is a mere chain of waterholes, and rarely reaches the Murrumbidgee, being lost in reedbeds.

The Darling-Barwon, from Mungindi to Wentworth, is about 1700 miles long. But the longest river in the Murray basin is the Condamine-Balonne-Culgoa-Darling-Murray, which rises at Toowoomba and is a continuous stream 2310 miles long. The Darling proper is navigable in time of freshets as far as Walgett, 1758 miles from its confluence with the Murray. Altogether the Murray River system provides 4200 miles of more or less navigable waterway. The Murray is usually navigable for seven months (July to January), but the Darling is sometimes too shallow for a year or more at a time. A comprehensive scheme of locking is proposed for these rivers, primarily to improve them for irrigation, but also to assist navigation.

The north-eastern tributaries are smaller, but of considerable length. The Macquarie, 590 miles long, rises in the hills west of Jenolan, flows

northward through Bathurst, Wellington, Dubbo, and Warren, and is usually lost in marshes before reaching the Darling. The Namoi, 430 miles long, drains the Liverpool Range and the south-west of New England; Tamworth, Gunnedah, Narrabri, and Walgett are important towns on or near it. The Bogan, Castlereagh, and Gwydir are each about 350 miles long. The Paroo and Warrego, nominal tributaries of the Darling on its north-west bank, are of little importance except in flood-time.

The chief coastal river is the Hunter-Goulburn, about 350 miles long, which rises in the Cassilis Gate already described; the upper Hunter is really a tributary. Singleton, Maitland, Cessnock, and Newcastle are the chief towns in its valley. The Hawkesbury, about 335 miles long, is known by different names in various parts of its course, which were discovered independently and named before it could be ascertained that they were connected. Its farthest source is that of the Mulwarree Ponds Creek near the southern end of Lake George. This creek runs north to join the Wollondilly a little north of Goulburn, and under the latter name traverses deep gorges (of which Burragorang is the best-known) in the ranges west of Berrima and Picton until it receives the Cox River from the Blue Mountains. Thence known as the Warragamba, it flows through another gorge into the Nepean, takes that name, and proceeds NE. past Penrith to meet the Grose; from the junction with this river the stream is known as the Hawkesbury, and passes Richmond and Windsor to enter the drowned estuary at Broken Bay.

The Shoalhaven, over 200 miles long, rises behind Moruya, flowing due north in an ancient valley to Marulan. Here it has been captured by the lower Shoalhaven, a coastal stream which has cut a gorge 1600 feet deep across its course. Braidwood in the upper valley and Nowra near the mouth are the only townships worth mention.

The Clarence is another complex system, many north-south streams (the Timbarra, Nymboida, etc.) having been captured by a coastal stream which enters the sea below Grafton. The main stream, nearly 200 miles long, drains all the north-eastern side of New England. The Richmond, farther north, is 160 miles long. The Macleay, a striking river, is another composite. The Guyra rises under Ben Lomond and picks up the Chandler (an almost parallel stream) and the Apsley running north from the Hastings Range; the united stream, known as the Macleay, traverses a deep gorge, emerges into alluvial flats, and enters the sea at Trial Bay. All the upper tributaries have canyons of their own, and the Wollomombi, Dangar, and Apsley falls are fine sights in flood-time. The Manning, Hastings, and Bellinger have been already mentioned. The south-coast streams (Tuross, Clyde, and Bega), each about 70 miles long, are of little importance. The Snowy River, which rises under Mount Kosciusko, flows 170 miles through the south-east of New South Wales before entering Victoria. Bombala is the chief town in its basin.

Artesian Water.—The Great Artesian Basin underlies 80,000 square miles in the north-west of New South Wales. The southern boundary runs through White Cliffs, Bourke, Dubbo, Narrabri, and Boggabilla. There are 486 bores in the State, arranged chiefly in two belts. The eastern belt lies east of the Barwon, bores being especially abundant near Coorallie and Moree; the other lies between the Paroo and the Culgoa. Boronga bore, near Boggabilla, is one of the most important; it is 4338 feet deep, and supplies over one million gallons daily. The bores are chiefly of value for watering stock. Seventy of them, mostly in the eastern belt, supply some four million acres, divided into bore-water trusts; this renders small grazing holdings possible.

Population.—At first glance the population map presents a very chequered appearance. This is due to the mingling of several controls, which can, however, readily be differentiated. As usual, rainfall and topography exercise the chief influence; but mineral deposits and centralization are also potent factors.

The dominant population-line (isopleth) runs from Hay to Moree; all to the west is sparsely populated, all to the east moderately populated. This line almost coincides with the 10-inch winter isohyet, which practically controls the wheat-crop and determines the western boundary of agriculture and close settlement. All to the west is pastoral, except the silver-lead region round Broken Hill and the copper region round Cobar. The relative distribution of population in the west depends chiefly on communications and water frontage. The three least settled areas in the State are round Ivanhoe (between the Darling and the Lachlan, and but recently linked to the railways) and round Wanaaring and Milparinka, remote alike from the Darling and from railways. The mining-fields of Tibooburra and White Cliffs probably account for the larger settlement between the two latter areas. The next main isopleth agrees fairly closely with the 30-inch isohyet, both in the north and as regards the chief gates that break up the highlands. The three major centres of settlement away from the coast are the Wagga-Albury, Young-Orange and Armidale areas, each of them on the western slopes of one of the three massifs described earlier. Though the eastern sides are nearer the coast and the capital, they are in general too rugged for close settlement, as is well shown in the north, where the slopes near Drake (Clarence valley) and Nowendoc (Manning valley) are almost uninhabited. The rugged area of the Federal Territory is also sparsely inhabited, and in the eastern part of the main central plateau settlements are comparatively rare except along the western railway line. The tongue of low population reaching down the Cassilis Gate almost to Sydney coincides largely with the barren sandstone, which is practically useless for grazing or agriculture.

The coastal regions of close settlement are scattered somewhat irregularly. The metropolitan area (including Sydney and suburbs) accounts for 43 per cent of the whole State. If the four adjoining counties are added, the percentage rises to 57. This congregation of people is in part due to the peculiar arrangement of the coal outcrops. Mines at Newcastle, Maitland, Lithgow, and Wollongong are all on the exposed rim of a buried basin of coal, which is also found 3000 feet below Sydney itself. Tongues of close settlement extend along all the railway lines, and important tourist centres have grown up on the sterile sandstones round Katoomba and Mount Victoria; elsewhere dairying, orchards and agriculture are the chief occupations of the people.

An interesting, somewhat isolated population inhabits the extreme north coast round Lismore. Here fertile soils and heavy rainfall have off-

set the distance from markets, so that dairying, timber-getting, cane-growing, orchards, etc., flourish, and support the eighth town in the State. Similar but less important settlements cluster round Grafton and Bellingen. The south coast has lagged behind the north, though it has been settled far longer. A district which is bound to grow rapidly is the irrigation settlement west of Narrandera, where a new railway is built to Griffith. The Federal capital area (south-west of Goulburn) is very sparsely populated, being essentially a sheep-grazing region. Canberra is seven miles west of Queanbeyan on the Goulburn-Cooma line, and is to have railway connection with Yass on the north, and with Jervis Bay via Queanbeyan on the east. The Commonwealth's Military College is at Duntroon, just outside Canberra. The whole Territory is 940 square miles in area (see CANBERRA).

Products.—The wool trade is by far the most important in the State. Forty-three per cent of Australian *sheep* belong to New South Wales, though the numbers have decreased from 56 millions in 1890 to 35 millions in 1922-3. The value has not varied much, being usually about £14,000,000 for wool and mutton. Sheep are spread through the State (except on the north coast, where other industries are more profitable), and are most densely distributed over the tablelands and western slopes. Here, however, they have rivals in farming and mining, but in the drier western plains they reign supreme. The merino breeds constitute 80 per cent of the whole. The coarse-woolled breeds are chiefly Lincoln and Lincoln crossed with merino. As in other States, rabbits are a menace to the pastoral industry. Rabbit-proof fences totalling 100,000 miles have been put up, notably along the western and north-western borders and from Bourke to Corowa. Their cost has amounted to £6,000,000.

Of *cattle* New South Wales has only half the number reared in Queensland. They are most numerous in the wetter regions, especially in the north-east, where the county of Rous (round Lismore) contains about 10 per cent of the whole number. About 60 per cent are contained in the coastal counties, including most of the dairy cows. Inland, the northern tableland is important, but the other regions are much less dense, while the whole western division (i.e. the area west of a line from Mungindi to Moulamein) contains only half as many as the single county of Rous. Dairies are almost confined to the coast. The principal breeds, according to Trivett, are Shorthorns, Herefords, Jerseys and Ayrshires; the chief crossbreds are between Shorthorns and one or other of the other three.

The region of greatest *wheat* production is in the Riverina, and extends thence north-east to Molong along the western slopes. The control is purely that of rainfall, and the next grade (100 bushels to the square mile) extends almost across the State. The low rainfall in the Cassilis Gate is probably responsible for the break in the belt hereabouts. The outer limit is ever moving westward, but agrees very closely with the 10-inch winter rainfall (April to October). A little more rain is needed in the north than in the south, to counteract the greater evaporation. Very little wheat is grown in the moist coastlands.

The *forest* areas cover about eight per cent of the State, confined mainly to the wetter coastal districts. Forests are of two types. Over most of the area east of the 20-inch isohyet they consist of eucalypts, but along the north coast are large softwood 'brushes,' akin to the tropical forests of Queensland, and (according to Baker) controlled largely by the presence of fertile basalt soils. The county of Rous, the Dorrigo plateau (behind Bellingen) and the upper Hastings valley contain most of the 'brushes.' Cedar, hoop pine, beech (*Gmelina*), black bean, rosewood (*Dysoxylon*), and sassafras are the chief cabinet and softwood timbers of the State. The eucalypts have somewhat specialized habitats also. Ironbarks are commoner in the coastal regions and warmer tablelands, and tallow-wood (*Eucalyptus microcorys*) along the north coast. Murray gum (*E. rostrata*) is ubiquitous in Australia, but forms forests along the Murray. Blackbutt (*E. pilularis*) occurs along the coast also. Less valuable boxes and stringy-barks grow throughout the highlands, while an allied genus (turpentine) is found along the coast. On the drier western slopes is the valuable cypress pine (*Callitris*).

The *sugar* industry is confined to the north-eastern corner of the State. Acreage and production have decreased somewhat since 1896, as dairies have developed so greatly in the counties of Rous, Richmond, and Clarence. There are only about 400 employees, and the small mills are now closed, three larger ones handling the whole output; these are situated at Maclean on the Clarence River, Wardell on the Richmond, and Condong on the Tweed. The *maize*-crop is second only to the wheat-crop. It requires more moisture and more heat; half the crop, therefore, is grown round Grafton, Kempsey, and Lismore on the north coast. Inverell and Tumut on the western slopes, and Windsor in the Sydney district, are also large producers. The *wine* industry is scattered all through the east and south of the State. Maitland and Albury are the chief centres, while Liverpool, Mudgee, Penrith, Singleton, Wagga, and Wentworth have each about one-sixth of the production of the two first localities.

Mining is a very important branch of industry in the State. In 1922 an average of 30,904 men were employed; 21,492 worked on the coal-mines in the Newcastle-Bulli basin, 4712 on silver, lead, and zinc at Broken Hill, and 4700 were scattered through the rest of the country. The paramount importance of Broken Hill is obvious. For the period 1916-19 metals to an annual average value of over five millions were obtained from Broken Hill; during the next two years the industry was completely dislocated by strikes, but is recovering. Their geology and mineralogy is discussed elsewhere, but notes on their situation deserve consideration here. Broken Hill is an outcrop of Cambrian or older rocks structurally akin to South Australian deposits; it is, in fact, only 30 miles across the boundary, and has always looked to Adelaide as its base. About 250 miles away south-westwards is Port Pirie, where much of the smelting is done, and the fluxes come largely from Iron Knob. On the other hand, it is 600 miles from the coast near Sydney, and has never had much direct connection by the coach-routes through Wilcannia, etc. A railway is now being built from Condobolin through Mount Hope, Ivanhoe, and Menindie to Broken Hill—a stretch of some 350 miles; the line will open up some of the least settled parts of the State, and greatly increase the pastoral wealth of the region traversed. At Yerranderie, about 80 miles SW. of Sydney, on a tributary of the

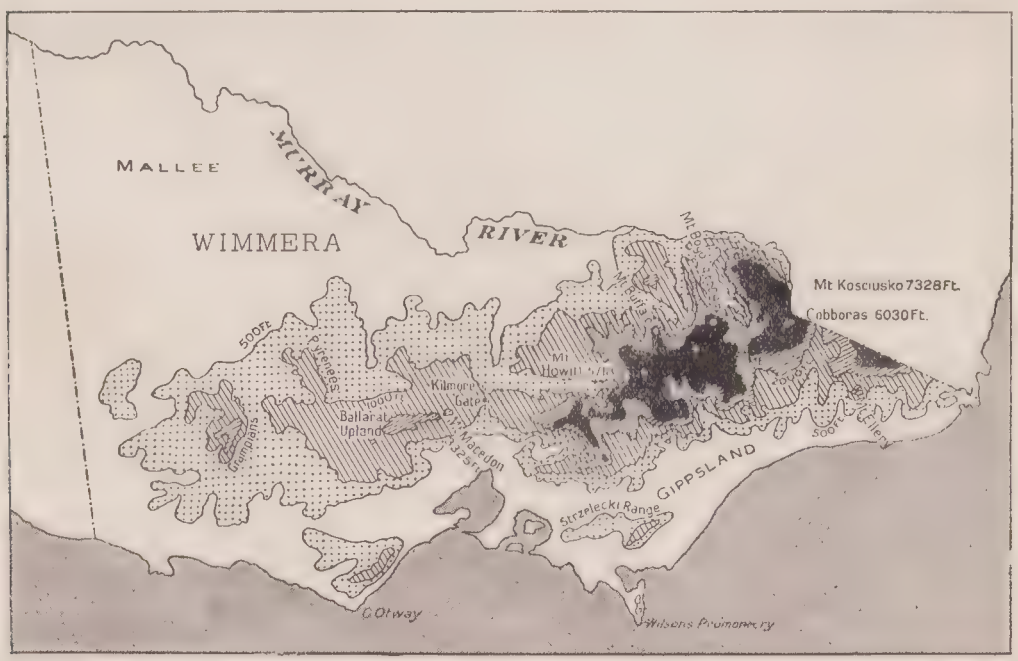
Wollondilly, there are smaller but valuable silver-mines.

The State's *coal* supply is the best in the southern hemisphere. Pittman has estimated that the Sydney basin contains 115,347 million tons of coal. This basin includes three series of payable coal-seams. The upper (Newcastle) series is the chief, and outcrops at Newcastle (N.), Lithgow (W.), and Bulli (S.). It has also been worked from a shaft 3000 feet deep in Sydney, which is in the centre of the basin. The middle series is worked chiefly near Maitland; the lower (Greta) series, which contains the thickest and best coal, is worked chiefly near Cessnock, but isolated areas of the same age are found at Wingen (70 miles NW.) and at Ashford on the Queensland border. The coal that outcrops in the Clyde River gorge (20 miles W. of Jervis Bay) is of the same age. The Newcastle district raised seven million, the Bulli district two million, and the Lithgow district one million tons of coal in 1922. On the western rim of the basin kerosene shale (torbanite) has been developed in the gorges at Newnes, Hartley, and Joadja. Coal is exported chiefly from Newcastle and goes to Chile, New Zealand, Java, India, United States, and the Philippines. Foreign export took nearly three million tons in 1921; the other Australian States (chiefly Victoria and South Australia) took about 2¾ million; and five million tons were used in the State.

Gold is of comparatively small importance. Nearly half the total supply comes from the Cobar district, especially from Canbelego. At Araluen in the Moruya basin, and at Adelong and Gundagai near the middle Murrumbidgee, there are important dredging plants. *Copper* is also a minor product, the value in 1922 being barely a twentieth of what it was in 1918. The Cobar district, for many years the largest producer in the State, has of late years supplied none. Tasmania and New South Wales are equal producers of *tin*, and are considerably ahead of the other States. It is found chiefly in the granite slopes on the north-west of the New England plateau. Emmaville, Tingha, Wilson's Downfall, and Glen Innes were the chief producers in 1920. A later find of considerable value is Ardlethan, on the edge of the Murrumbidgee irrigation areas in the south. Dredges are used largely in the north.

Iron deposits of any value are rare. The chief is near Cadia, south of Orange; a second is at Carcoar in the same district. At Turrawan near Narrabri on the north-western slope a valuable deposit of iron oxide has been developed lately. A large amount of iron is manufactured by the Broken Hill Company at Newcastle; the ore comes from Iron Knob in South Australia, and is brought to the coal-fields for smelting. Among other valuable minerals are *opals* from White Cliffs (north of Wilcannia) and Lightning Ridge (north of Walgett); *alunite* from Bullahdelah near Port Stephens; and *diamonds* from Tingha in New England.

Victoria.—*Area*: 87,884 sq. m. all in temperate zone. *Rainfall*: all over 10 inches; maximum at Weeaproinah (78.9 inches). *Population* (1921): 1,531,280 whites, 111 aborigines. *Chief Towns* (1921): Melbourne (795,100), Ballarat (36,411), Geelong (31,686), Bendigo (30,401), Warrnambool (7730), Castlemaine (5331), Mildura (5101), Hamilton (5097), Maryborough (4744), Ararat (4653), Stawell (4413). *Stock* (1922-3): horses, 494,947; cattle, 1,785,660; sheep, 11,765,520. *Chief Products*: wool (1922-3), 102,467,950 lb.; wheat (1922-3), 35,697,220 bushels; potatoes (1922-3), 148,354 tons; wine (1922-3), 1,717,490 gallons; apples (1922-3), 2,089,017 bushels; butter (1922-3), 84,355,940 lb.; cheese (1922-3), 3,754,960 lb.; milk (1922-3), 249,321,522 gallons; timber (1922-3), 118,336,000 super feet; gold (1922), 106,872 fine oz.; coal (1922), 559,284 tons. *Railways* (1921-2): 4375 miles. For statistics of stock, products, etc., not given here see separate articles on Horses, Sheep, etc.



Topography.—In Victoria the highlands run east and west, separating the northern and north-western plains from the coastal plains in the south. Nevertheless the grain (running north and south), so noticeable in the rest of eastern Australia, is still obvious in three striking features of the Victorian highlands—the Omeo Gate, the Kilmore Gate, and what we may call the 'Howitt' scarp. These are all probably due to north-south faults, as the stratigraphy shows.

The Benambra highlands are the continuation into Victoria of the Kosciusko highlands. The name 'Bowen Mountains' is given to the highest portion, containing the Cobboras (6030 feet); a long plateau extends north to Mount Gibbo (5764). This region comprises about 600 square miles over 3000 feet. A more isolated area (which is, however, linked to the Nimmitabel plateau in New South Wales) of about 300 square miles of highland has Mount Ellery (4255 feet) as its highest point. The Omeo Gate links the head-waters of the Tambo to the Mitta Mitta, which has captured all the previously south-flowing streams near Omeo. It is a remarkable gap about 2800 feet high, between two plateaux of 4700 feet. The chief plateau of Victoria contains Mount Bogong (6509), Mount Feathertop (6306) and five other summits over 6000 feet; it covers an area of about 2700 square miles above the 3000-ft. contour, and extends westward to the heads of the Goulburn and Delatite. Here are Mounts Howitt (5718) and Tamboritha (5381). A spur runs north to Mount Buffalo (5645), which overlooks Bright on the Ovens. The Dargo and Bogong 'high plains' are sheets of older basalt, covering streams of an ancient river-system now 3000 feet above the present watercourses. West of Mount Howitt the plateau character gives place to a much dissected block of highlands, whose main ridge is called the Hume Range. A high spur projecting southwards ends in Mount Baw Baw (5062), but only a few peaks rise even to 4000 feet. The highlands rapidly decrease in height to the west; Mount Disappointment at the side of the Kilmore Gate is only 2631 feet, and Mount Dandenong, at the western end of the southern rim of the Yarra valley, is 2077 feet high.

The Kilmore Gate is just over 1100 feet high. Northward extend lowlands as far as the Gulf of Carpentaria; just to southward lies Melbourne, and to the west stretches an extensive region of uplands, almost all between one and two thousand feet. Mount Macedon is a local elevation reaching 3325 feet, but nothing else as high is met with except in the Grampians far to the west. Low spurs extend north from this 'Ballarat upland' (as we may call it from its chief town); one spur culminates in Mount Alexander (2430 feet), the other forms the Pyrenees. The Mount William Gap separates these uplands from the Grampians to the west. These are faulted blocks of ancient sandstone, which run north and south; Mount William, the highest point, reaches 3829 feet. There are several isolated uplands near the coast—the Otway Range, rising to 1912 feet in Mount Sabine, and the Strzelecki and Buln Buln ranges in western Gippsland, with Mount Fatigue (2110 feet). A granite outlier that builds up Wilson's Promontory rises to 2350 feet.

The plains of Victoria flank the main highlands to north and south. They have their greatest extent in the north-west, which includes the Mallee and the Wimmera; the former is characterized by a close-set scrub of dwarf eucalpyt (mallee) which is gradually giving place to wheat; the Wimmera is better watered, and traversed by several important rivers. The same holds true for the plains farther east, which are described later in connection with the rivers and irrigation.

The southern valley may be considered in three divisions. In the west are bare basalt plains extending from the Glenelg to Geelong; the central division consists of the drowned portion forming Port Phillip and Western Port, and the adjacent plains south of Mount Dandenong—these are better watered, and carry good timber; the eastern division comprises Gippsland and, gradually narrowing, extends eastwards to Cape Howe.

Hydrography—Coasts.—The Glenelg discharges near the western boundary, and thence eastwards the coast is low to near Cape Bridgewater (441 feet). Cape Nelson, close by, has an important light. In Portland Bay is the oldest permanent settlement in the State, now an important port connected by rail and steamer with the capital; off this bay is Lady Julia Percy Isle, a noted resort for seals. Port Fairy is a small port farther east. Warrnambool, near the mouth of the Hopkins, is the chief town along this coast. The main products of all this district are wool, potatoes, pigs and dairy produce.

As the Otway ranges are approached the coast becomes more rugged, but there are settlements at Port Campbell, Apollo Bay, and Lorne. Cape Otway is crowned by a powerful light 300 feet high, visible 24 miles.

Port Phillip entrance, between Point Lonsdale and Point Nepean, is about 1½ miles wide. The strong tidal stream over the shallow entrance is called the 'Rip.' The bay is 31 miles long and about 20 wide; Corio Bay, near its mouth, runs 15 miles farther west. The coast is for the most part low, except in the north-eastern and south-eastern corners. Queenscliff, with a fort and pilot station, lies just inside the western head; a railway runs thence to Geelong and Melbourne. Bellarine Peninsula, rising to 463 feet, bounds the south of the Corio Bay arm. On it is Portarlington, a small settlement facing towards Melbourne. Geelong, an important town on Corio Bay, collects the produce of the western plains, and is connected with Melbourne and Ballarat by rail; there is also some inter-State trade. A long stretch of low coast-line, carrying little or no settlement, extends along the western shore of Port Phillip. At Point Cook, about 10 miles from Williamstown, is the military flying school. The last-mentioned town (really a suburb of Melbourne) occupies a tongue of lava that hems in Hobson's Bay; it is a minor naval base, and has many factories. Port Melbourne, across the Yarra, is the regular place of call for large oversea steamers, but inter-State steamers and other vessels usually proceed via the Coode canal and lower Yarra to Melbourne itself.

Commercial Melbourne, about two miles north of the bay, has grown up chiefly on the northern slopes of the Yarra round the first settlement made by Batman and Fawkner. The chief residential portions lie to the east and south-east, extending almost uniformly within a radius of eight miles or so. The eastern shore of the bay is much more picturesque than the west, and residences are now almost continuous to Frankston, 27 miles down; Mornington,

Dromana and Sorrento, nearer the Heads, are residential townships for holiday-makers.

Between Port Phillip and Western Port lies Mornington Peninsula; its southern point is Cape Schanck, a bold headland with a light visible 23 miles. Western Port is almost filled by two large islands, Phillip Island and French Island. A naval station (Flinders) is situated near Stony Point on the western shore. Cape Wollamai, at the south-eastern end of Phillip Island, is a picturesque granite headland. San Remo and Powlett River are small tourist and dairy towns, while Wonthaggi and its hinterland have valuable coal-fields. The rocky peninsula of Wilson's Promontory is a national reserve; to the east is Corner Inlet, with Toora and Westport on its northern shore; Port Albert and Alberton are fishing-grounds farther east.

The Ninety-mile Beach is a continuous sandy beach, much broken by inlets and small streams. A line of lagoons lies behind the dunes, and thence low tea-tree country extends for miles. The long line of Gippsland lakes opens through the beach by an artificial cut made in 1889, the old entrance being closed by drifting sands. Steamers ply inland 45 miles from Lakes Entrance to Sale on the Thomson River, and for 20 miles up to Bairnsdale. Eastwards lies a similar sandy beach, extending as far as the Snowy River, where there is a small settlement at Marlo. Cape Everard is a granite headland carrying a powerful light. Point Hicks, near Ram Head, is possibly the first point sighted by Cook in 1770. Somewhat east is Mallacoota Inlet, the shallow estuary of Genoa River. Gabo Island, off this inlet, is formed of red granite, which is quarried for export; a powerful light, visible 20 miles, crowns the island. Six miles east is Cape Howe on the State boundary.

Rivers.—The main river is, of course, the Murray, which forms the State's northern boundary for about 1200 miles. It has been described in connection with New South Wales. Below Albury it flows through a broad flood-plain, at first 500 feet above the sea, but at the South Australian boundary only 57 feet above. The tributaries that enter it east of Swan Hill have at first steep courses, and flow through well-watered country; those farther west flow almost wholly through low plains and, as the rainfall is small, usually fail to reach the main river. The Mitta Mitta rises near Mount Hotham, flows south, and then bends sharply to the north, passing through deep gorges near Mount Bogong; it is 125 miles long, and Tallangatta is the chief settlement on it. The Ovens River (110 miles) rises on the north side of Mount Hotham and flows through Bright and Wangaratta. The Goulburn River—the chief tributary, 280 miles long—rises near Wood's Point, and at first flows due west through Alexandra to Seymour; here it turns to the north, and flows normally to join the Murray, passing through Nagambie, Murchison and Shepparton. The Campaspe (100 miles) waters Rochester, and reaches the Murray at Echuca. The Loddon (155 miles) rises near Daylesford; Maryborough, Inglewood, and Kerang are on or near its banks. The Avoca rises on the Divide, flows north through Avoca and Charlton, and splits into two main streams, neither of which reaches the Murray; they empty into the shallow basins known as Lakes Tyrrell and Bael Bael. The Wimmera (155 miles) drains the northern Grampians, and has captured several parallel streams near the uplands, but dwindles away on the plains, and ends blindly in lakes (Hindmarsh, Albacutya, etc.), 100 miles from the Murray. Stawell, Glenorchy, Horsham, and Dimboola are some of the chief towns in its basin.

Of the coastal rivers the Glenelg (280 miles) is the longest; it rises in the Grampians, and flows west nearly to the boundary of South Australia, then turns to the south and, passing through Casterton, reaches the sea at Nelson. The Hopkins (135 miles) and its longer tributary Mount Emu Creek (170 miles) drain the basalt plains from Ballarat and Ararat to the sea. The Barwon runs through broken country south-east of Ballarat; it used to enter Port Phillip at Geelong, but now passes through Lake Connewarre to the open sea. The Yarra, a fine stream 115 miles long, rises near Mount Baw Baw and flows west, parallel to the upper Goulburn; it originally drained south towards Sorrento, but was drowned when Port Phillip was formed. Nowadays its stream is salt from near Kew downwards through Melbourne itself into Hobson's Bay. The Latrobe flows east along the broad valley between the southern Gippsland ranges and the main highlands; it receives the Macalister from the north, and passes through Lakes Wellington, Victoria, and King to reach the sea. The Tambo (90 miles) and Mitchell also enter by Lake King. The Victorian portion of the Snowy River is 95 miles long; it flows through rough country south of the border until the coastal plain is reached. Orbost is the only town on the Victorian portion.

Lakes.—Several lakes (e.g. those due to silting and deviation in the Mallee and Wimmera, and the sand-bar lakes of Gippsland) have been already mentioned. In the western basalt plains irregular hollows in the lava sheet, between the valleys of the Barwon and Mount Emu Creek, receive local drainage; Lake Corangamite has an area of 72 square miles. Others, such as Bullen Merri and Koroit (Tower Hill), are due to subsidence in volcanic areas; while some (e.g. White Lake near the Glenelg) are, according to Gregory, due to the removal of soluble limestone.

Irrigation, etc.—Artesian supplies are not of great importance, but small bores (about 200 feet deep) are in operation round Sale in Gippsland. In the Mallee the extension of the Pinnaroo (South Australia) basin has been tapped by about 80 useful bores; the water is obtained by pumping, only three having a true artesian flow. Many other bores are scattered through the north-west, but a great number are brackish or salt. The need of level agricultural land and an adequate water-supply have confined the chief irrigation areas to the central northern and north-western slopes of the highlands. The works are roughly of two kinds—complete irrigation, and stock-watering; for an account of these see IRRIGATION.

Population.—Topography, rainfall, and accessibility have determined how settlement has progressed in Victoria, perhaps more clearly than in most other parts of Australia. In an especial degree the population congested round the capital, no less than 50 per cent of the whole living in 'Greater Melbourne' in 1921. The area containing more than 16 persons to the square mile comprises Bourke, Grant, and Mornington counties round Port Phillip, and extends west and north-west to include Bendigo, Castlemaine, and Ballarat. The population has been drawn in this direction by rich mineral deposits, and by open agricultural lands with good rainfall (20-30 inches). The nearer

counties to the north-east are rugged and heavily timbered, and are only sparsely inhabited even along the rivers. The next zone (over eight persons) includes the wet coastlands, where dairying reigns supreme, as well as the irrigation areas and rich wheat-lands of the north. Warrnambool, Morwell, Shepparton, and Wangaratta are centres in this zone. More sparsely-settled districts lie west and north-west, and include the Wimmera and eastern Mallee. To the east are similar (but rugged) districts, with many small farms and small mines in Delatite and Benambra. Central Gippsland, round Bairnsdale, belongs to this zone. The dry scrubby north-west of the Mallee, the plateaux round Mount Howitt, Mount Hotham and the Cobboras, and the counties to the east beyond the Tambo are still almost uninhabited.

Products.—The number of *sheep* has not altered appreciably since 1880, newer districts taking the place of those where farms have replaced sheep. The 'Western District' is their chief habitat, especially the Hopkins valley, but the whole area between Seymour and the Glenelg is well-stocked.

Among less important zones are the Wimmera, the northern districts, and Gippsland. In the outer counties to north-west and east there are very few sheep. The chief sheep-area lies between the 20- and 30-inch isohyets. Districts with over 30 inches carry distinctly fewer sheep. If the country is accessible and fairly level, it is better suited for dairies and farms; if it is rugged, it is usually devoted to cattle.

Cattle are most numerous in regions of heavy rainfall, southern Gippsland and Mornington being the chief areas for both types of cattle; the Western District comes next in order for dairy cattle, and the north-east is important for other cattle. The whole of the State, however, except the north-west—where the large county of Weeah has only about 2000, and Millewa 400 head—is cattle country. Among the chief dairy centres are Colac, Terang, and Warrnambool in the south-west; Alberton, Maffra, Morwell, and Bairnsdale in Gippsland; Poowong and Berwick, nearer Melbourne; and Shepparton, Wangaratta, and Kerang north of the Divide.

The production of *wheat* has steadily increased from 10 million bushels in 1880 to 36 million in 1922-3. In the northern and north-western districts wheat is most abundant; three counties, Moira (Shepparton, Numurkah, and Tungamah), Borung (Horsham, Murtoa, Dimboola, and Warracknabeal), and Karkarook (Walpeup, Ouyen, and Birchip) grow over 40 per cent of the whole. Other important northern districts are Swan Hill, Kerang, Boort, and Korong (all in or near the Loddon valley), and Wycheproof near Birchip. The chief wheat-growing areas are enclosed between the 10-inch and 15-inch winter isohyets. Apart from the localities noted above, outlying districts south of Ballarat and north of Sale are of special interest. Both are 'rain shadow' regions in the lee of mountains, where the rainfall is considerably below that of neighbouring counties; wheat therefore to some extent replaces dairying, which needs more moisture.

Oats are an important crop in the north-central region, extending approximately from Ararat to Albury. They are also grown to some extent throughout the wheat areas. About 88,000 acres are devoted to *fruit* (apples, etc.), of which half are in the three counties of Bourke, Mornington, and Evelyn; the chief centres are Doncaster, Lilydale, Eltham, Frankston, and Berwick. Proximity to Melbourne and a rainfall of 30 inches are the chief controls. *Potatoes* are an important crop along the south coast. Dandenong, Berwick, Warrnambool, and Belfast, with the Ballarat and Daylesford districts, are the chief producing areas; their rainfall is usually from 25 to 30 inches.

There are about 12 million acres of *forest* in the State, distributed chiefly in the south, east, and centre, where the rainfall is adequate. The western basalt plains are almost treeless, though forests grow where protected from stock and fires. In eastern Victoria the stringy-bark (*Eucalyptus amygdalina*) and messmate (*E. obliqua*) cover almost all the highlands. Other important timbers of the slopes are ironbark, grey box, blue gum, spotted gum and blackbutt; red gum occurs along the Murray. The most valuable cabinet timbers are the blackwood (*Acacia*) and evergreen beech, both of which occur only in the wettest coast-lands. About half the output of sawn timbers comes from the upper Yarra and the Otway forests.

One out of every three Australian *vineyards* is in Victoria, which ranks next to South Australia as a wine-producer. Seventy per cent of the wine comes from the Mildura and Rutherglen districts, both on the Murray. Other important centres are Swan Hill, Shepparton, Benalla, and Chiltern, but there are smaller areas round Lilydale, Maryborough, Ararat, and Stawell.

Victoria has few important metals except *gold*, and the output of this has gradually diminished in value from 3½ millions in 1899 to about half-a-million in 1922. The auriferous country occurs patchily among the older rocks of the highlands. The chief producers are Bendigo, Beechworth, Castlemaine, and Ararat. Maryborough and Ballarat are of much less importance. *Antimony* in marketable quantities is found near Heatheote. *Tin* occurs in the coarse granites of the north-east near Beechworth, and along the Mitta Mitta valley to Cassilis. There is also tin-sluicing on the south coast, near Toora on Corner Inlet. *Coal* occurs in two forms, as bituminous coal of Jurassic age, and as brown coal of lower Tertiary age. The former is worked chiefly at Wonthaggi and Korumburra, east of Western Port; it is reported that 30 million tons are still available. Brown coal is distributed along a belt from Ballarat to Gippsland, showing at Lal Lal, Altona, Morwell, and Alberton. The Morwell bed is one of the thickest in the world—780 feet of hydrous brown coal; it will undoubtedly be of great importance as a power-producer in the near future. The scheme for using it to supply Melbourne with electricity is discussed under MORWELL.

TASMANIA.—*Area*: 26,215 sq. m. all in temperate zone. *Rainfall*: all over 10 inches; maximum at Mount Lyell (116.7 inches). *Population* (1921): 213,780 whites. *Chief Towns* (1921): Hobart (53,803), Launceston (24,305). *Stock* (1922-3): cattle, 218,197; sheep, 1,558,494. *Chief Products*: wheat (1922-3), 569,587 bushels; potatoes (1922-3), 101,201 tons; apples (1922-3), 3,127,509 bushels; timber (1922), 45,564,000 super feet; gold (1922), 3431 fine oz.; silver (1922), 794,585 fine oz.; copper (1922), 5616 tons; tin (1922), 679 tons. *Railways* (1921-2): 873 miles. For statistics of stock, products, etc., not given here see separate articles on HORSES, SHEEP, etc.

Topography.—Tasmania is a triangular expanse of land, mostly over 1000 feet in elevation. The lowlands are confined to the broad valleys of the Tamar and the Derwent, which both run NW. and SE., parallel to the grain of the country. A third parallel valley is formed by the Gordon-Huon valleys, which join near Lake Pedder in the south-west of the State. The chief block of highlands occupies the north-central portion of the island, and rises to 5069 feet in Cradle Mountain towards the west. More important is the broad stretch of the central plateau, everywhere over 3000 feet, which contains numerous large lakes. This plateau is truncated somewhat abruptly on the north and east, forming the Western Mountains (Dry's Bluff, 4257 feet); to the south the descent is more gradual, the Derwent having eaten away a large portion of the plateau. West and south of it there lies a series of high ridges or narrow plateaux—Eldon, Hugel, Field West, and Wellington—all over 4000 feet high. In the south-west is another parallel series of mountains—the Wilmot, Arthur, and Hartz ranges—from 3000 to 4300 feet in height. The highest point of the island (Legge's Peak, 5160 feet) is on the isolated Ben Lomond massif in the north-eastern corner, almost completely cut off from the rest of the State by the valley of the South Esk. Many isolated portions of the central plateau fringe its rim; thus to the north-west are outliers including Mount Lyell (2750), Mount Zeehan (2500), and Mount Bischoff (2598), round which are some of the richest ore-deposits in the world. In the extreme east is Mount Nicholas (2812), dominating the chief coal area, while farther south in the same uplands is Mount Brown (2598).

Hydrography—Coasts.—The north-eastern corner is Eddystone Point, with a powerful light visible 18 miles. To the north-west lies Ringarooma Bay, into which enters a river of the same name; Boobyalla is a small town at the mouth. Bridport lies at the head of the next (Anderson) bay. Stony Head, a conspicuous headland nearly 300 feet high, is a little east of the mouth of the Tamar. The estuary, called Port Dalrymple, has a lighthouse at Low Head; Launceston, 38 miles up the river, can be reached by boats drawing 21 feet, and Georgetown and Beaconsfield are important towns on and near the estuary. Port Sorell and Devonport are drowned river-mouths to the west. On the latter (the estuary of the Mersey) is an important town of the same name, connected by steamer with Melbourne and Launceston; vessels of 22-ft. draught visit it, and large supplies of potatoes and oats are exported. Ulverstone, at the mouth of the Leven, is the next large town, but Burnie is the chief port for this district; it lies on Emu Bay, and is the terminus of the north coast railway and of the mining railway to Zeehan. Wynyard near Table Cape has a light visible 27 miles, and 25 miles west is Stanley on Circular Head, a mass of basalt nearly 500 feet high. Oats, potatoes, fruit, and stock are exported. Robbins Island and Barren Island lie off the north-western corner of the State, and protect the north coast from westerly gales. Walker Island has been separated from Robbins Island since 1800.

The whole of the west coast is practically uninhabited, except for one or two small villages and the port of Strahan on Macquarie Harbour. The coast is rocky and sterile, and usually has a heavy swell rolling in from the south-west. Arthur River enters the sea about 25 miles south of Cape Grim, and Pieman River 45 miles farther on. Mounts Heemskirk and Zeehan were probably the first portion of the island sighted in 1642 by Tasman; the range of which they are part rises to 4739 feet in Eldon Mount. Macquarie Harbour, 19 miles long, is a drowned estuary of the Gordon. A light on Cape Sorell at the western head is visible 20 miles. The King River enters the harbour, and Strahan is near its mouth; behind it lies a rich mining district, from which a railway runs to Mount Lyell, Zeehan, and Burnie. Farther up the harbour is Pillinger, connected with Mount Lyell by tram. South of Cape Sorell the coast is low and bare to Point Hibbs, but then rises gradually to a height of several hundred feet near Port Davey. Off the rocky and dangerous south coast is Maatsuyker lighthouse, visible 25 miles.

The south coast is a fine example of a drowned coast-line. Bruni Island (27 miles long) is a submerged ridge, the original valley to the west forming D'Entrecasteaux Channel. Small towns largely engaged in fruit-growing—Ramsgate, Hythe, Folkestone, Franklin—lie on its western shores, and there are many timber mills in the hinterland, especially along the Huon River. The island rises to 2000 feet, and is densely wooded; the light at the south-western point (Bruni Head) is visible 22 miles. Storm Bay, between Bruni Island and Tasman Peninsula, receives the Derwent River, on whose estuary stands Hobart, immediately at the foot of Mount Wellington. The largest steamers can berth here, and there is direct and regular communication with the other States and with New Zealand and London. The chief exports are wool, grain, timber, hops and fruit. Newtown and Glenorchy are suburbs of Hobart; across the estuary lie Risdon and Bellerive. The river is navigable to New Norfolk. Frederick Henry Bay, an inlet at the head of Storm Bay, leads to Sorell and Norfolk Bay, and almost isolates Tasman Peninsula. This picturesque district terminates in Cape Pillar, a cliff over 900 feet high formed of basalt columns; on its southern coast is Port Arthur, the old convict settlement, and it is connected with the mainland only by Eaglehawk Neck (which is only 20 yards wide at high

tide) and East Bay Neck, through which at Dunally there is a canal big enough to take small vessels. Maria Island is a granite outcrop halfway between Tasman and Freycinet peninsulas. The latter, with Schouten Island at its southern end, encloses Oyster Bay, on which stands Swansea. Thence the coast trends due north, and is cliffy as a rule, but there are small flats at Bicheno, Falmouth and St. Helens.

Rivers and Lakes.—Most of the rivers have been mentioned above, but a few merit further description. The South Esk, the longest (160 miles from source to sea), rises within a few miles of the coast, behind St. Marys. In its basin are Fingal, Longford and Perth. Its principal tributary is the Lake River, which rises on the plateau in an indefinite divide where the Shannon also has origin; the Macquarie, a tributary of the Lake River 73 miles in length, flows through Ross and Campbelltown. A little farther north the Meander comes in from the west; the farming towns of Deloraine and Westbury are in its valley. At Launceston the North Esk joins the South Esk, and their united stream, called the Tamar, enters Bass Strait 40 miles northwards.

Of equal importance with the South Esk is the Derwent (107 miles). It rises in Lake St. Clair in the west of the central plateau, which drains into it through the Nive, Dee (from Lake Echo), Ouse (whose tributary the Shannon comes from the Great Lake) and Clyde (from Lake Sorell). Another tributary, the Jordan (58 miles), flows through comparatively populous districts east of the plateau; in its valley are Oatlands, Kempton, and Brighton. Hamilton and Bothwell on the Clyde, and Glenora on the Derwent itself, 10 miles above New Norfolk, are settlements of some importance.

The peculiar physiography of the Ouse and Shannon has led directly to the development of the only large hydro-electric plant yet established in the Commonwealth. The Ouse runs just west of the Great Lake, gradually cutting its way into the plateau until a deep valley is formed. The Great Lake, which had formerly an area of 42 square miles, is drained by the Shannon, whose canyon begins lower down. A little south of the lake there is a difference in level of 1250 feet between the Shannon and the parallel course of the Ouse, only 3½ miles away. A dam has been built at the lake, which increases its area to 50 square miles; the head of water thus established is utilized in a way fully described under HYDRO-ELECTRIC DEVELOPMENTS.

Population.—There are three centres of population in the State—Hobart, Launceston, and the north-western mining district. About 50 per cent of the population live round Launceston and along the north coast, about 40 per cent round Hobart and in the south-eastern districts; the rest are in the mining division. The south-west is almost entirely uninhabited; the three large counties of Lincoln, Franklin, and Montgomery only contain 327 persons between them, and Arthur has none. These sparsely inhabited regions consist largely of bleak granite plateaux, or an almost impenetrable jungle of temperate rain-forest. There are, however, timbers of economic value which will lead to settlement later.

Products.—Only about two per cent of the *sheep* in Australia are reared in Tasmania; the number has remained almost stationary for 50 years. Sheep are congregated chiefly in the uplands between Hobart and Launceston—especially near Bothwell, Oatlands, Hamilton, and Campbelltown—but some are found in all settled districts. Tasmanian stud sheep are valued by mainland flock-owners. The wool-product for 1922-23 was 10,218,550 lb. *Cattle* form only 1½ per cent of the total for Australia. About one-third are dairy cattle, largely distributed along the north coast, where 70 per cent of the butter factories are clustered round Stanley, Wynyard, and Ringarooma. For other cattle King Island in Bass Strait and the Derwent valley near Hamilton are important areas. Dairies exist chiefly in the lowlands that receive from 30 to 50 inches per year; other cattle prefer the rougher country of the central and Ben Lomond districts.

Wheat is of much less importance than oats, and the output is diminishing. The two chief regions are near Longford and Westbury in the north, and Brighton and Richmond in the south. *Oats* are grown in the dairy country to a much greater extent than wheat. The chief centres of production are Devonport, Ulverstone, and Burnie on the coast, and Longford inland. Sheffield, Deloraine, Wynyard, and Westbury in the north, and Oatlands in the south, are also important districts; but oats are grown throughout the eastern portion of the State. The two outstanding fruit-crops are apples and raspberries. Out of two million bushels of *apples* grown in 1915 more than three-quarters came from the vicinity of Hobart. The chief centres are Franklin and other places at the mouth of the Huon, Kettering, New Norfolk, Brighton and Glenorchy. *Pears* are similarly distributed. *Raspberries* are grown from New Norfolk to Franklin. Eighty per cent of the large *potato* crop comes from the north coast, chiefly in the vicinity of Sheffield, Ulverstone, and Wynyard. Oatlands, New Norfolk, and Richmond are the centres of the less important southern area.

Considering its small area, the State has an important *timber* industry. Over 45½ million super feet were sawn in 1922. The whole State, except the plateaux, is more or less covered with forests, especially along the west and south coasts. In the east the trees are eucalypts, but a different growth—due to the extremely heavy rainfall—obtains in the western and Ben Lomond districts. Wherever the rain exceeds 50 inches per annum, the eucalypt is replaced by the evergreen beech (*Nothofagus*); there are also valuable areas of softwood pines. The blue gum (*Eucalyptus globulus*) and stringy-bark (*E. obliqua*) are perhaps the chief hardwoods; blackwood (*Acacia melanoxylon*) is an ornamental wood. All these grow to larger proportions than on the mainland. The chief sawmills are on the lower Huon and near Hythe; but an area of great importance lies north-east of Launceston, round Lilydale and Scottsdale.

As a *copper* producer the Mount Lyell district is second only to Cloncurry in Queensland, about 1500 men being employed; the mining towns of Queenstown and Gormanston communicate by rail with Strahan and Pillinger on Macquarie Harbour and with Burnie on the north coast. For *tin* there are two centres. The mines now most productive occur along the Ringarooma River at Pioneer, Gladstone, and Branxholm, but the famous Mount Bischoff mines, at Waratah in the north-west, are still giving large yields. Important *silver-lead* deposits occur at Zeehan, halfway between Mount Lyell and Waratah; Mount Farrel and Mount Magnet also have valuable silver-lead deposits. The *gold* output has been gradually decreasing in value since 1899, the quantity pro-

duced in 1922 being 3431 fine oz. Beaconsfield mine is the chief producer; Matthina in the north-east has nearly as large a yield, and even more gold is recovered from the copper of Mount Lyell and allied mines. There are three series of *coal* measures. The Permo-Carboniferous measures are worked to a slight extent near Latrobe on the Mersey. The Mesozoic deposits cover a large area of the State, though much faulted by basic lava intrusions. The Tertiary (brown coal) deposits are widespread, but are hardly exploited at all. Almost all the State's coal is derived from the St. Marys district, the chief mines being at Cornwall and Fingal. W. H. Twelvetrees estimates that there are about 68 million tons available in these two formations; but neither type equals the Newcastle series, as they are higher either in sulphur or in ash content. See PHYSIOGRAPHY and GEOLOGY.

Gr.T.

Geology. 1. *Introduction.*—An observer taking a bird's-eye view of Australia and Tasmania would see the great island continent carpeted nearest the coast with strips of dark-green eucalypt forest on the E., SE., and N., and again in the SW. part of Western Australia, with an outlying strip upon the Flinders Range of South Australia. The remainder would present a curious patchwork, partly dull green sagebush, saltbush, and other salsolaceous herbs of the steppes; partly the grasses of the savannahs, and the dark-green mulga scrubs; and partly patches of red and brown sand (the desert areas) dotted with oases which fringe the worn-down stumps of ancient inland mountains.

White specks in numbers would be conspicuous in this patchwork wherever the saline surfaces of dead lakes (playas) reflect the sunlight, or where—except in late summer—the highlands of New South Wales and Victoria are white with snow. The emerald isle of Tasmania, the S. coast of South Australia, the SE. coast of Victoria, and (in places) the inland uplands of tropical Queensland would appear jewelled with lakes. To the north the great island of New Guinea would loom large, its alpine ranges whitened with snow, its mountainous uplands—where visible through breaks in the mist—showing verdant, grassy slopes encircled by sombre pines and cypress. Lower still would be seen the dense dark-green jungle of the coastal plains.

Australia is well known as the home of the eucalypt, and this characteristic tree is in itself an epitome of climatic conditions in late geological time. The most primitive types of eucalypt develop their leaves with the broad surface horizontal, pointing to a time when there was no need to take special precautions to conserve moisture. In the vast majority of eucalypts, on the other hand, the leaves hang with their broad surface vertical, so as to offer as little evaporating surface as possible to the sun's rays; but even these in early stages of growth show the atavistic tendency to develop leaves with the broad surface horizontal

This habit connotes a former better rainfall, and this in turn suggests a former higher relief for the Australian land-surface, inducing a more abundant convectional rain. Thus the eucalypts record the most recent climatic changes of Australia, and prepare us for those evidences of peneplained and downward-warped mountain chains, with recently uplifted coast-lines, that harmonize with its large, disintegrated drainage system. This disintegration of the drainage, again, harmonizes with the shallow, wide-bottomed valleys, choked with rock debris; with the vast red-soil plains; and with the kunkars, laterites, 'pindan' ironstones, and porcellanites, so characteristic of the interior of Australia, as of all countries where rainfall is scant and evaporation great. But these inland areas of low rainfall do not lack the rich plant-foods which have accumulated during the sabbatical periods of drought, as is proved by the inland extension of the wheat-belt through methods of dry farming, and the consequent contraction of the central waste areas.

In countries of low rainfall (ten inches or less annually) and with very few rainy days throughout the year, the capillary action of percolated rainfall in the soil and subsoil and underlying rock greatly predominates over the leaching action of the rainfall. The sparse rains, for a few days in the year, tend to wash soluble mineral matter from the surface to deeper levels, but during each of the (perhaps 350) dry days in the year evaporation at the surface of the ground induces a constant upward flow by capillarity of subsoil water with mineral matter dissolved in it. Further evaporation leads to this mineral matter being deposited as a hard superficial crust, from two to ten feet in thickness. If the dominant soluble mineral in the underlying rock is lime, a surface crust of tufaceous limestone (nodular kunkar) forms; if iron is the dominant soluble mineral, laterite and pisolitic ironstone (pindan ironstone) result; if silica, the surface of the ground becomes enriched in silica, and porcellanites and quartzites result. These siliceous crusts become disrupted through the great diurnal changes of temperature in the interior of Australia, and form vast sheets of angular blocks like freshly broken road metal. The 'gibber' plains of central Australia owe their origin to this process.

2. *Coastal Physiography.*—A glance at the map explains some of the chief reasons for the shape of the Australian coast. The chief coastal indent—the Gulf of Carpentaria—is to be correlated with strong tectonic lines, approximating to a meridional direction, which determined the position of the northern end of the Cretaceous basin. The dominant folds in Arnhem Land, on the W. side of the Gulf, are parallel to its shoreline; the folds in the Palaeozoic rocks of the Cape York peninsula are approximately meridional with a very heavy downthrow at the trough of the Little River coal-field. The southern shore of the Gulf seems related to the WNW.-ESE. fold axes which run through the Etheridge and Gilbert goldfields. The Great Australian Bight, again, appears to be of tectonic origin, lying between the old fold-mountains (recently block-faulted) of the Mount Lofty and Flinders ranges near Adelaide, and the vast peneplain of Western Australia, with its worn-down folds, shaped in plan like an inverted S.

The two deep indents—Spencer Gulf and St. Vincent Gulf—are clearly 'senkungsfelder,' the southern end of a great rift valley which extends by way of Lake Torrens (92 feet above sea-level) to Lake Eyre (about 60 feet below sea-level). Bass Strait, as shown by the geological evidence, is another rift valley crossing the older grain of the country, and so is the depression in which lie Torres Straits.

A fall in sea-level to the extent of about 200 feet would re-unite Tasmania and Australia, and a fall of only about 100 feet would re-unite Australia and Papua. This could also result from a negative 100-foot movement of the ocean, such as probably occurred towards the

culmination of the latest ice age; then the sea-level in temperate and subtropical latitudes was probably 100 feet lower than at present, owing to the locking-up of water to form the great ice-sheets.

Cape Leeuwin and Cape Naturaliste are certainly due to a heavy coastal trough-fault just E. of them, which in that SW. part of Western Australia has determined for a great distance the trend of the western coast-line. Hobson's Bay (Port Phillip) south of Melbourne is probably on a meridional rift valley; the Hunter valley and the port of Newcastle are situated on a NW. to SE. rift valley. That whole section of the Queensland coast which for 1200 miles NNW. from Rockhampton runs parallel with the Great Barrier Reef owes its trend to powerful downthrows to the east, perhaps compensating for the epeirogenic movement of land to the west. The trend of the E. and W. shores of Tasmania is parallel to axes of folding. It is obvious that the S. coast of Australia (as well as the whole of its N. and NW. coasts) is of an Atlantic type. On the contrary, the SW. coast of Western Australia, the E. and W. coasts of Tasmania, and the NE. coast of Queensland are, as regards their trends, of a Pacific type. The SE. coast of Australia does not appear to be either wholly Atlantic or wholly Pacific; the term 'sub-Pacific' has been suggested for it.

As regards geological structure, the Australian coast at Fremantle consists of recent dune rock cemented by lime, derived chiefly from remains of mollusca and *Lithothamnion*. Numbers of artesian wells, sunk in this rock near Perth, yield copious supplies of artesian water. Cretaceous rocks have been penetrated there at about 1000 feet below sea-level. Similar calcareous dune rock forms the coast at Cape Northumberland (South Australia), at Warrnambool (western Victoria), and at Sorrento, on the E. side of the entrance to Port Phillip; so far it has not been proved to carry artesian water.

From Cape Naturaliste to Cape Leeuwin the coast is formed of recent dunes resting on granite, while towards Albany a deeply indented coast of granite makes its appearance, with dunes lodging in the hollows. Close to Albany, and extending inland to the foot of the Stirling ranges, is a remarkable spongilite deposit of Janjukian (Miocene) age largely formed of sponge spicules. Farther eastwards, near Cape Riche, is a small basin of similar spongilite rocks, while near Cape Arid the coast is masked by the Recherche Archipelago, mostly ancient crystalline rock. East of Cape Arid to Fowler's Bay, in the direction of Eyre's Peninsula, the coast-line is formed of nearly perpendicular cliffs up to 250 feet in height, with a further gentle rise of about 290 feet inland towards the Nullarbor Plains. At the base they are formed of white chalky rock with layers of flints, the whole capped by polyzoal and molluscan limestones. At present the whole of this series is attributed to some time between Eocene and lower Miocene. About 900 feet below sea-level, at the Madura bore (W. of Eucla), the Tertiary limestone rests on a thick series of Cretaceous greensands with a well-preserved marine fauna. Along this 500 miles of unbroken coast-line, and along the extension of the coast farther eastward for another 500 miles from Fowler's Bay to the head of Spencer Gulf, there is not a single river. As the rocks inland are mostly porous Tertiary limestones, almost horizontal, there is no surface run-off of the rain-water, which sinks in swallow-holes to tortuous subterranean tunnels and is discharged below the foot of the sea-cliffs—as in the catavothra of Greece. From Fowler's Bay round the headlands of Eyre's Peninsula and the lower end of Spencer Gulf the coast-line is formed partly of Tertiary sediments, partly of pre-Cambrian schists, gneiss and granite—the last-mentioned well seen in the North and South Neptunes at the entrance to St. Vincent Gulf. A plain of erosion along the coast, part of a block-faulted peneplain, crosses Yorke Peninsula to the E. side of St. Vincent Gulf, and extends to the W. side of the Mount Lofty ranges. This coast is formed partly of post-Pliocene flood-loams (which N. of Port Augusta contain remains of the crocodile *Pallimnarchus pollens*), partly of richly fossiliferous Tertiary marine limestones, partly of Permo-Carboniferous glacial beds, and partly of the highly folded Cambrian and Proterozoic series with their glacial beds. For general interest and variety this part of the coast-line is probably unequalled elsewhere in Australia. The strand-line has here recently been raised 12 feet, and Port Adelaide and Port Wakefield are built on the land thus naturally reclaimed. Evidence of such an emergence can be traced round the greater part of Australia; it is probably due to a world-wide sinking of the sea-level. Kangaroo Island is formed of Proterozoic rocks, capped by Tertiaries and basalt at its eastern end. The Cambrian and Proterozoic rocks continue along the coast E. of Backstairs Passage to the mouth of the Murray River at Port Elliot. An upward movement of the land hereabouts has reclaimed the Tertiary basin which extends far inland from this part of the coast; the Murray and Darling Rivers have become engrafted, and the lower Murray has been rejuvenated, forming an antecedent stream entrenched in a well-marked canyon.

From the mouth of the Murray to Cape Northumberland the coast-line is mostly formed of loose dune sand, or consolidated dune sand like that of Cape Northumberland. The dune rock rests on marine Tertiaries, on recent alluvials of the Murray basin, or on small inliers of granite. Inland from Cape Northumberland are the recently extinct volcanoes of Mount Schanck, Mount Gambier, etc. From Cape Northumberland to E. of Warrnambool the coast is similar, with occasional outcrops of Tertiary sediments, capped by basaltic lava, until the Otway coast is reached. This is formed of freshwater Jurassic strata, in places containing small seams of coal.

East of the dune rock of Sorrento the Victorian coast is formed of Tertiary rocks and older basalt; then of the Gippsland coal-measures, in which the claw of a dinosaur and teeth and scales of *Ceratodus* have lately been discovered. At Cape Liptrap the cliffs are partly Silurian and partly Ordovician slaty rocks, while at Wilson's Promontory they are granite. Beyond Corner Inlet there follows to the NE. a long stretch of sands deposited in slack water between the southerly-flowing East Australian current and the current flowing easterly out of Bass Strait. This sand has engrafted many of the rivers, and formed the Gippsland lakes; the reclamation has probably been helped by a fall in sea-level. At Gabo Island and Cape Howe granites form a rückland coast, which continues (with the addition of Ordovician, Silurian, and Devonian sediments) to Moruya and Milton.

North of Milton the coast partakes more of the nature of a forland coast; a distinct coastal plain is developed from sediments of the Permo-

Carboniferous and Triassic basins, and continues N. for over 200 miles to Port Stephens. In its deeply indented estuaries, harbours, and drowned valleys (e.g. Jervis Bay, Port Hacking, Botany Bay, Port Jackson, Broken Bay, Port Stephens, etc.), and in the entire absence of marine Tertiary deposits, this part of the land shows evidence of recent sinking. From Jervis Bay to Wollongong the strata in the sea-cliffs are rich in Permo-Carboniferous marine fossils, while those of Bulli and the cliffs towards Newcastle, 100 miles to the north, show frequent coal-seams, and abound—especially near Newcastle—in Permo-Carboniferous fossil plants.

From Port Stephens to near Grafton the coast is mostly of an indented type, with drowned valleys between hills coming close to the coast, numerous bar harbours, and a narrow coastal plain fringing Carboniferous, Devonian, and probably Ordovician strata. An outlying part of an immense belt of serpentine, intrusive into middle Devonian radiolarian rocks, touches the coast at Port Macquarie. From the Clarence River to the Richmond there is a forland coast of Jurassic coal-measures—the Clarence basin. A low, indented, rückland coast—again of Ordovician strata, cherts, tuffs, and quartzites, capped by alkaline basalts and acid pitchstones—stretches from Ballina to near the mouth of the Brisbane River. A forland coast, in part Jurassic, stretches from the Brisbane River to Gladstone. Interesting volcanic rocks (comendites and riebeckite trachytes, together with alkaline andesites and basalts) form conspicuous domes and sugar-loaves a short distance inland from the coast, which is there fringed with dunes—the largest in Australia—up to 800 feet high. At Maryborough and Great Sandy Island marine Cretaceous rocks outcrop, with a basin of productive coal (the Burrum Basin, the only deposit of Cretaceous coal worked within the Commonwealth) immediately overlying them. From Gladstone to Cape York there is a remarkable coast, chiefly of the rückland type, with mountain ranges from 2000 up to 5000 feet high (Bartle Frere 5438 feet) coming mostly close to the coast-line, and having high islands like Hinchinbrook (3560 feet) close inshore. This part of the coast and coastal shelf is so heavily faulted, and studded with small islands that have survived the block-faulting, as to deserve Suess's title of 'panzer-horst.' In some places there is a coastal plain, e.g. at the Cretaceous coal-basin of Broad Sound, at Port Mackay, and NW. and SE. of Townsville North; in others the old rocks (chiefly Carboniferous strata with *Lepidodendron* and *Phillipsia*, or Devonian rocks with massive coral and stromatoporoid limestones, both systems intruded by granites) form bold cliffs and headlands. This remarkable part of the coast-line is opposite to the Grand Canal of Australia, which runs between the Great Barrier Reef and the mainland. The high coastal hills are obviously part of the old main divide, its eastern slope with nearly all the easterly-flowing rivers being faulted eastwards under the Barrier. This coast terminates in granite, capped with the horizontal upper Cretaceous desert sandstone that forms Cape York. From Cape Howe to Cape York, a distance of 2150 miles, marine Tertiary deposits are wholly unknown. From Cape York round the rocks of the Gulf of Carpentaria the coast is of a low, forland type, at first formed of desert sandstone, then of late Tertiary and post-Tertiary freshwater deposits, with an inner zone of marine Cretaceous rocks. It is thought that the submarine outlook of the northern part of the great artesian basin lies somewhere towards the southern shore of the Gulf of Carpentaria.

On the W. side of the Gulf are numerous islands, formed of Permo-Carboniferous rock. A short distance inland from the mouth of the Roper River the late Cainozoic sediments give place to Cambrian sandstones and limestones, the latter on the Daly River being largely formed of *Salterella hardmani*. These limestones, many thousand feet thick, rest on an older volcanic series. From here to Darwin the coast is formed chiefly of Cretaceo-Tertiary and Permo-Carboniferous rocks, with an occasional low-lying outcrop of older Palaeozoic or pre-Cambrian rock. Proofs of recent uplift of the land are everywhere evident, except between Arnhem Bay, the English Company's Islands, and Cape Arnhem, where there appears to have been a recent downward movement. Elsewhere upraised post-Tertiary muds, with echinoderms and crayfish and banks of dead coral, are clear proofs of recent uplifts. One of the most beautiful parts of the whole Australian coast is the north-eastern extremity of Arnhem Land. Tectonic disturbances, present as major faults running NE. and SW., are crossed by minor faults throwing NE. At Point Charles lighthouse, near Darwin, rolled specimens of *Ammonites* and *Scaphites* occur in great numbers. At Port Darwin the coast is composed of whitish shales and sandstones, containing numerous casts of *Belemnites*, and in places consisting almost entirely of radiolaria. These were originally deposited at a considerable depth—which suggests that since upper Cretaceous times (the epoch to which these rocks belong) there has been an equivalent upward movement of this coast.

3. *Palaeogeography and Present Relief.*—The photographs of the relief-model of Australia and Tasmania show the broad physical features of the Commonwealth, while the orographic map gives the actual contour-lines, and the tectonic map the chief trend-lines. These maps, together with the sections, show that Australia is essentially a vast peneplain. This has been in part abandoned by the ocean, in part warped upwards or downwards in arches and compensating troughs; and the warping has been accompanied by heavy fractures. The latest of the true fold-mountains dates back to Carboniferous time; for, although in eastern Queensland the Permo-Carboniferous rocks are steeply tilted, they are never closely folded as the Carboniferous rocks often are. Great peneplanation took place in Permo-Carboniferous time, followed by a considerable transgression of the sea in a wide belt sweeping inland on either side of Sydney, then swinging N. through Queensland at least as far as Townsville. In Triassic and Jurassic time Tasmania, Bass Strait and southern Victoria were covered by great lakes and swamps, in which the coal-measures of that age were formed. Contemporaneously a vast lake stretched from at least as far E. as Brisbane more or less continuously to Lake Eyre, a distance of nearly 1000 miles. It is not known yet how far this lake stretched meridionally, but it must have been at least 500 miles. Gondwana Land was probably still in existence, as far as can be judged from the evidence available in Australia, India, New Zealand, South America, and Antarctica. In late Jurassic or post-Jurassic time there supervened gigantic intrusions of diabase (dolerite), on a scale perhaps unprecedented in geological history; these took the form of sills, which dominate the physical features of Tasmania, the Kar-

RELIEF MODEL OF AUSTRALIA AND TASMANIA
The black portions show low-level plains

RELIEF MAP OF AUSTRALIA AND TASMANIA, SHOWING TREND LINES

roo, Antarctica, and British Guiana. It seems highly probable that these intrusions were connected with the sinking-in of Gondwana Land, the consequent compensating warping-up of the sea-floor, and probably a further shallowing of the sea-floor through submarine extrusions of the dolerite; and the same phenomenon may account for those world-wide transgressions of the oceans in Cretaceous time which Suess considers one of the most conclusive pieces of evidence for occasional rises in sea-level. Australia was no exception to the rule that epicontinental seas of vast size transgressed all the world over in Cretaceous time. During the older Cretaceous (Rolling Downs) series the portion of the continent which is still preserved was severed by a sea stretching from the Gulf of Carpentaria to the Bight. The marine fauna of this sea is essentially that of a local Mediterranean. On the other hand, the Cretaceous rocks of the W. coast of Western Australia have a cosmopolitan Cretaceous marine fauna, closely resembling that of India. Thus the old land barrier which united eastern Australia with India in Permo-Carboniferous (Permian) time does not seem to have been wholly broken down in early Cretaceous time. In upper Cretaceous time marine conditions were largely replaced by lacustrine, lake-surfaces (with small marine basins here and there) covering about half of the whole Australian area. During this period was deposited the so-called desert sandstone, which at one time probably covered about three-quarters of Queensland, one-third of South Australia, and at least one-fifth of New South Wales.

In early Miocene time a considerable portion of southern and north-western Victoria, part of north-western Tasmania, the extreme south-western corner of New South Wales, a large area round St. Vincent and Spencer gulfs, and a still larger area at the head of the Bight, were submerged. It is important to note that the submergence crept inland at least as far as the surface of the peneplain at Lake Cowan, near Norseman in Western Australia, where deposits of marine sponge-spicules are superimposed on the peneplain. Marine molluscan remains, apparently of Janjukian (Miocene) age, have also been found resting on this old peneplain. The vast peneplain of Western Australia and the Northern Territory, and possibly that of eastern Australia as well, are approximately of the same date.

It has been argued that the Australian and Tasmanian peneplain survived without serious warping into Pliocene time. This provisional conclusion is based on the uniform character of the Pliocene flora—as far as the few fragments of it that are preserved allow us to judge—which may be due to the fact that at this time the land over large areas was reduced nearly to sea-level. That some warping of the peneplain had commenced, probably as far back as the Oligocene, is proved by the fact that in Victoria the so-called 'older basalts,' (of perhaps Eocene or Oligocene age) are capped by the lower Miocene marine beds; and there is evidence to show that Tasmania, after being joined to Australia in early Tertiary times, was divided from the mainland by a strait in middle Tertiary or early Pliocene time, and then re-united or nearly re-united in late Pliocene or Pleistocene time. The Tasmanian aborigines, ignorant of the building of sea-going canoes, were thus able to migrate into Tasmania from the mainland. That the warping of the Australian and Tasmanian peneplain was chiefly post-Miocene is proved by the locally folded and uplifted lower Miocene beds in the Mount Lofty ranges, near Adelaide. Also the latest great outburst of volcanic energy all over Australia (the Northern Territory excepted) took place in post-Miocene time. Moreover, the glaciation of the Tasmanian highlands, and of those of SE. Australia, took place in late Pliocene or Pleistocene time; and these glaciations were almost certainly contemporaneous with accentuated crust-warping, though it is not intended to suggest that there was necessarily a causal connection between the two phenomena (there possibly may have been). Next, the existence of abundant remains of large herds of Pliocene or Pleistocene marsupials —some of elephantine proportions—in what are now low-lying arid regions, along with the discovery of remains of the late Pliocene or Pleistocene crocodile, *Pallimnarchus pollens*, as far south as Lake Torrens near Port Augusta, demands a higher rainfall, moister climate, and probably higher relief for the interior of Australia than it at present possesses. Then too, the canyons of the upper Flinders, of the eastward-flowing New England rivers (the Macleay, the Hastings, etc.), and of the Blue Mountain rivers, the Shoalhaven River, etc., imply that no very great time has elapsed since the warping; otherwise some of the valley walls would be flared down and reduced to gentle slopes.

All over the highlands of Tasmania, as well as over the Kosciusko plateau, there is evidence of a succession of glacial epochs. These were perhaps synchronous with the recent maximum glaciation in Antarctica and in South America—possibly with the phases of the Great Ice Age in the northern hemisphere.

Amongst the newest of the tectonic movements has been the development of the great tensional faults which have so strongly block-faulted the Flinders Range and the main eastern divide, especially along the Barrier Reef area—where, as in the neighbourhood of Cairns, the upper end of the Barron River is left hanging on the upthrow side of the fault-block. The fault which bounds the Darling Ranges of Western Australia on the west is probably a development of late Pleistocene time.

4. *Stratigraphical Features.*—The geological succession in Australia may be indicated as follows:—

Post-Tertiary group. *Recent* system (duration about 20,000 years): (1) River alluvium and sand dunes, with hard calcareous dune rock. Aboriginal kitchen middens. Laterites ('pindan' gravels and nodular ironstone). Nodular tufaceous limestone ('kunkar'). Salt deposits and muds of the 'playas.' Active crater of Mount Victory in Papua; recent craters of Mount Gambier (South Australia), Tower Hill near Warrnambool (Victoria). The Great Barrier Reef of Queensland. Maximum thickness of dune rock 1000 feet. (2) Raised beaches, mostly 15 feet above sea around Australian coast. In Papua recent coral rock extends up to 2000 feet above sea-level. Submerged peat beds about 100 to 200 feet below sea to N. of Sydney. (3) *Helicidae* sandstone of Bass Strait islands, and *Planorbis* limestone west of Cloncurry in Queensland. *Pleistocene* system (duration about 1,000,000 years): (4) Mammaliferous drift and old lake muds, with remains of *Diprotodon, Nototherium, Thylacoleo, Thylacinus, Sarcophilus*, together with *Pallimnarchus pollens, Megalania*

prisca, Genyornis, Canis dingo, etc. In places these deposits may date back to late Pliocene, contemporaneous with—(5) Glacial deposits of western Tasmania and of the Kosciusko plateau.

TERTIARY group (duration about 55,000,000 years). *Pliocene* system (duration about 6,000,000 years; approximate age 7,000,000 years): (6) Basalt sheets (thickness 300 feet) of the fissure eruptions in E. and SE. Australia and Tasmania, Kangaroo Island (South Australia), and Bunbury (Western Australia). These range from Pliocene through Pleistocene to Recent. Newer 'deep leads' of alluvial gold and tin in eastern Australia and Tasmania. Werrikooian marine series of Victoria. *Lower Pliocene* or *Upper Miocene* system: (7) Older marine Pliocene beds (thickness about 1000 feet) of Adelaide. Kalimnan marine series (thickness 150 feet) of Victoria. Possibly Launceston lake beds belong here. (8) Belt of alkaline lavas and tuffs (thickness 500 feet) from Coleraine to Springsure, about 1500 miles. Melilite and nepheline basalts of Tasmania. (9) *Ostrea sturti* beds (thickness possibly 100 feet) of the lower Murray River. *Lithothamnion* limestone of Hallett's Cove, Adelaide. *Miocene* (Janjukian) system (duration about 12,000,000 years; approximate age 19,000,000 years): (10) *Cellepora gambierensis* limestones, passing into chalk with flints (thickness 80 to 1000 feet) around the Bight. At Table Cape (Tasmania) the oldest Australian marsupial, *Wynyardia bassiana,* occurs in this formation; *Lepidocyclina* occurs in places. Plantagenet series, Albany; Carnarvon marine Miocene series, over 1000 feet thick (both these are in Western Australia). Purari lignitic and oil-bearing series (thickness several thousands of feet) in Papua, with abundant *Lepidocyclina.* (11) Older basalts and tuffs (thickness 200 to possibly 1500 feet) and the older 'deep leads' of Gippsland (Victoria), New South Wales, and southern Queensland. Much laterite and bauxite are associated with this series. (12*a*) Important brown coal series of Victoria, with fossil plants and lignites. At Morwell, in Gippsland, these lignites are 888 feet thick. (12*b*) *Oligocene* system: *Balcombian marine beds* (thickness 400 feet) in Victoria. Port Moresby radiolarian cherts, etc., in Papua.

MESOZOIC group (duration about 135,000,000 years). *Cretaceous* system (duration about 65,000,000 years; approximate age 120,000,000 years): *Upper Cretaceous.* (13) Winton series, partly Cretaceo-Tertiary, (thickness 100 to 1000 feet) mostly of freshwater origin, with occasional erratics and with thin seams of coal in places. The sandstone is occasionally marine, with *Rhynchonella croydonensis.* The Burrum and Styx River coal-measures of Queensland probably belong hereabouts: also the radiolarian shales with belemnites of Fanny Bay, and the ammonite beds, both of Port Darwin; and the greensands and calcareous rocks of Eucla, Perth, Gingin, Carnarvon, etc., in Western Australia. *Lower Cretaceous.* (14) Rolling Downs formation (thickness 2000 feet) chiefly glauconitic sands, and clays, with abundant foraminifera, *Maccoyella, Cytherea, Crioceras, Lamna, Belonostomus, Notochelone, Ichthyosaurus, Plesiosaurus, Aeschna flindersensis.* The *Alveolina* limestones of New Guinea may perhaps be referred to this horizon. *Jurassic* system (duration about 35,000,000 years; approximate age 155,000,000 years): *Upper Jurassic.* (15) Diabase sills (thickness 500 to 1000 feet) of Tasmania. *Lower Jurassic.* (16) Sandstones (thickness 1000 to 3000 feet) of the great artesian basin, with lignitic coal in places. At Leigh's Creek, south of Lake Eyre, a 47-ft. seam of brown coal in this series. Coal-measures of Gippsland and Cape Otway; Walloon series of Queensland, with mineral oil. *Taeniopteris spatulata* is specially characteristic, and cycadaceous forms like *Otozamites,* and *Pterophyllum. Alethopteris* is also abundant, and *Unio eyrensis* numerous. The claw of a dinosaur allied to *Megalosaurus,* has been found in Victoria, also fossil *Ceratodus.* In Western Australia and Papua marine Jurassic rocks occur, with abundant ammonites. Opal-bearing rocks of White Cliffs (New South Wales) may be partly Jurassic. Clarence coal-measures of New South Wales, possibly Rhaetic in part. Productive coal-measures (thickness 3000 feet) of Tasmania. *Phyllotheca* present with *Thinnfeldia, Alethopteris,* etc. *Triassic* system (duration about 35,000,000 years; approximate age 190,000,000 years): (17) Bundamba sandstones and Ipswich coal-measures in Queensland. Hawkesbury series in New South Wales, with abundant fossil fish and large undescribed labyrinthodonts. Contains occasional ostracods and foraminifera and abundant *Estheria.* Much red and green tuff at base of series.

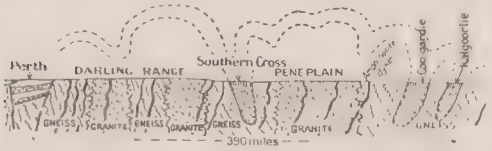
PALAEOZOIC group (duration about 360,000,000 years). *Permo-Carboniferous* (Permian) system (duration about 25,000,000 years; approximate age 215,000,000 years): (18) Acid granites of New England. Alkaline series of Kiama, New South Wales. (19*a*) Upper or Newcastle coal-measures (thickness 1500 feet) with 35 to 40 feet of workable coal. *Glossopteris* predominates over *Gangamopteris; Dadoxylon* abundant. The upper Bowen coal-measures of Queensland, and the Collie coal-field in Western Australia, are partly on this horizon. Dempsey series (thickness 2200 feet). Barren freshwater strata. Middle coal-measures (thickness 500 to 1800 feet), Tomago or East Maitland, about 18 feet of workable coal. Upper marine series (thickness 6400 feet), mudstones and sandstones, with abundant *Productus brachythaerus,* crinoids, 'glendonite' pseudomorphs, occasional glacial erratics in shales, and abundant *Fenestellidae.* Lower or Greta coal-measures (thickness 100 to 300 feet), with about 20 feet of workable coal. *Gangamopteris* predominates over *Glossopteris.* The Dawson and lower Bowen coal-measures (Queensland) probably belong here, as do the Mersey coal-measures of Tasmania and the Irwin coal-field of Western Australia. Lower marine series, with the Ravensfield sandstone and sodic basalts. *Carboniferous* system (duration about 85,000,000 years; approximate age 300,000,000 years): *Upper and middle Carboniferous.* (19*b*) The middle and part of the upper Carboniferous is represented in New South Wales by the Kuttung series, which contains acid and intermediate lavas and tuffs, with which are interbedded varve shales and tillites. In Victoria there are the Bacchus Marsh beds, over 2000 feet thick, with at least four beds of true tillite. At Wynyard in Tasmania, and Hallett's Cove near Adelaide, these tillites are very well developed. In Victoria and South Australia the tillites rest on beautifully striated pavements. In Western Australia a well-marked glacial horizon underlies the Irwin River coal-field. The *Achacopteris* beds of Victoria, the *Rhacopteris* beds of New South Wales, the *Aneimites* beds of Herberton and of Mount Budge in the Drummond Range, Queensland, probably belong to middle Carboniferous. (20) Sphene-granites of New England. (21) Bluegranites of New England. *Lower Carboniferous* (thickness 20,000 feet):

(22) Star series of Queensland, with *Lepidodendron australe, Aneimites,* and *Phillipsia.* The Burindi beds in New South Wales, with *Phillipsia, Productus semireticulatus, Syringothyris, L. volkmannianum, L. veltheimianum,* etc. In Victoria the Mansfield fish-beds and the Grampians sandstones may be included here, together with the fish-beds (with *Lepidodendron veltheimianum*) of the Drummond Range in Queensland. (23) Serpentine belt of New England, New South Wales. *Devonian* system (duration about 50,000,000 years; approximate age 350,000,000 years): *Upper Devonian* (thickness 10,000 feet). (24) *Spirifera disjuncta* quartzites of Mount Lambie, New South Wales, with *Lepidodendron australe.* Quartzites and red shales of Wellington and Twofold Bay in New South Wales, and Avon River sandstones of Victoria may belong here. *Middle Devonian* (thickness 9000 feet). Radiolarian cherts, reef limestones, and spilites of Tamworth, New South Wales. Burdekin series of Queensland, with reef limestone up to 7000 feet thick, an ancestor of the Barrier Reef. Buchan and Bindi limestones of Victoria, with andesites. Devonian rocks of Kimberley, Western Australia. *Lower Devonian* (thickness 14,000 feet). Murrumbidgee series, New South Wales, with *Receptaculites* and bony-plated fish-like *Asterolepis,* also a thick series of acid to intermediate lavas. In Victoria are the series of acid lavas and tuffs, the Snowy River porphyries. Dacites, quartz-porphyries, and granodiorites of this age occur in Victoria. Most of the granites of Tasmania are thought to be Devonian. Devonian rocks occur in Papua. *Silurian* system (duration about 40,000,000 years; approximate age 390,000,000 years): (25) Shales, sandstones, limestones, contemporaneous tuffs (thickness 3000 to 5000 feet). The type area is Yass in New South Wales. *Hausmannia* and *Encrinurus,* with the corals *Rhizophyllum* and *Mucophyllum* and *Pentamerus knightii,* are characteristic. At the base of the series is *Halysites* in great abundance. At Lilydale in Victoria, Chudleigh in Tasmania, and Chillagoe in Queensland, limestones of this age are well developed. They are frequently associated with radiolarian cherts. The west-coast conglomerates of Tasmania belong here. *Ordovician* system (duration about 90,000,000 years; approximate age 480,000,000 years): (26) These rocks (thickness possibly 9000 feet) are either littoral, like the Tempe Downs beds (south of the Macdonnell Range), with *Asaphus* and *Endoceras* abundant; or of the Victorian type—black shales, sandstones, graptolitic shales, with some sponge spicules, phosphatic slates, and cherts. They are also developed in New South Wales at Tallong, Mandurama, etc. The Brisbane schists and phosphatic argillites of Gladstone, Innisfail, etc., in Queensland may belong here. *Cambro-Ordovician* system: (27) The porphyroid series with breccias, tuffs, Dundas slates, etc., of western Tasmania. *Cambrian* system (duration about 70,000,000 years; approximate age 550,000,000 years): (28) This system (thickness possibly 10,000 feet) is chiefly developed in South Australia, and in the Northern Territory. The diabases and *Protospongia* cherts of Kilmore and Heathcote, and diabases, tuffs, etc., of the Hummocks, Dookie, and Mount Wellington in Victoria are probably upper Cambrian. In the Northern Territory thick sandstones overlie massive *Salterella* limestones, perhaps 7000 feet in thickness—another forerunner of the Barrier Reef.

PRE-CAMBRIAN group. *Proterozoic* system (age about 1,125,000,000 years): (29*a*) Beneath the above fossiliferous limestones is a vast thickness of basalts and basic tuffs, red shales, quartzites, thin limestones, etc. (Adelaide and Nullagine series). About half-way up in this series in South Australia are tillites up to about 1000 feet in thickness. (29*b*) The mosquito series of the Pilbara goldfield in Western Australia is a schistose group unconformably underlying the Proterozoic Nullagine series. At Kalgoorlie the Kurrawang conglomerates are probably Proterozoic, as are those of Goat Island (Tasmania) with mica schists; in the Mount Lofty and Flinders ranges the rocks of the Houghton magma, so rich in titaniferous iron and diopside, and connected with radium deposits, are also probably Proterozoic. The Casterton gneisses and schists of Victoria may also be Proterozoic, as well as most of the mica and quartz schists of the Northern Territory, and Cloncurry in Queensland. *Archaeozoic* system (age about 1,400,000,000 years): (30) Archaeozoic rocks are widely spread in Western Australia at Pilbara and most of the other goldfields, in the Musgrave and Macdonnell ranges, at Port Lincoln, etc., in South Australia, and over large areas of the Northern Territory.

Pre-Cambrian System.—The rocks of this age, comprising both Proterozoic and Archaeozoic formations, are developed on a particularly grand scale in Western Australia, South Australia and the Northern Territory; in fact about one-third of the whole area of Australia (approximately 800,000 square miles) is occupied by this vast crystalline complex. Pre-Cambrian rocks are developed in the Kimberley goldfield of Western Australia as well as at Darwin, and extend from the latter at intervals to Cloncurry in Queensland. In New South Wales they are represented by a belt of garnetiferous mica-schist, with amphibolites and gneiss, in the Barrier ranges of the Broken Hill silver-field. They are represented by schists near the Cobar copper-mines of New South Wales, and possibly by a thick series of crystalline schists in a broad belt of country stretching SSE. from Wodonga and Tallangatta through Omeo and Tongio West in north-eastern Victoria. The gneisses and schists of Casterton in Victoria, and the serpentine of Mount Wellington and a well-marked belt of mica-schist and white saccharoidal quartzite together with quartz conglomerates in Tasmania, are ascribed to this group. All the pre-Cambrian rocks of Tasmania appear to have been of sedimentary origin. In Western Australia at least three groups are present: (*a*) Archaeozoic older gneisses and greenstone schists (and jaspilites) with intrusive granite and pegmatite veins with numerous dykes of diorite, norite, dolerite, etc.; (*b*) Proterozoic rocks formed of coarse conglomerates together with phyllites, quartz-schists, etc.; (*c*) the Proterozoic basic and acid lavas and tuffs, red and black shales, quartzites, and laminated dolomites of the Nullagine series. Its basal conglomerate contains diamonds. The Stirling ranges of Western Australia may be of Nullagine age or older. The principal goldfields of Western Australia—one of which alone (Kalgoorlie) has produced to date over £100,000,000 worth of gold—are situated in rocks, probably of the first group, occupying deeply infolded basins, partly of pre-Cambrian basic lavas and tuffs, in the intrusive acid complex. The section on p. 534 shows these pre-Cambrian rocks to have been intensely folded, the trend of the folds being nearly meridional, but on the whole having the form of a very open inverted letter 'S.'

One can distinguish at least four of these great gold-bearing basins from east to west in the following order:—Kanowna, Boulder and Kal-



Diagrammatic Sketch, Perth to Kalgoorlie.

goorlie, Coolgardie, and Southern Cross. In the Pilbara district of Western Australia there is a considerable development of minerals of the rare earths, associated with veins of pegmatite traversing pre-Cambrian rocks; e.g. the tantalite (associated with tin-stone) found in this region occurs in sufficient quantity to control the whole of the tantalum market of the world. The mineral gadolinite, associated with well-crystallized monazite—and occasionally the rare radioactive mineral pilbarite, a lead-bearing uranium ore—also occur within this area. From the lead-uranium ratio it has been estimated that the age of these rocks is 1475 million years.

At Mount Painter (between the head of Spencer Gulf and Lake Eyre) the pre-Cambrian rocks comprise remarkably massive deposits with coarse mica-schists, containing an abundance of sapphire. These rocks are traversed by a huge lode containing radio-active minerals, such as monazite, torbernite, autunite, etc., together with a considerable amount of fluorspar. This lode has been traced along a continuous outcrop of over a mile, and in places is said to be over 20 yards in width—in places as much as 50 yards. At Radium Hill at Olary, on the railway line from Adelaide to Broken Hill, there is a considerable deposit of uranium-bearing titaniferous iron ore. At the surface outcrop this is stained lemon-yellow to orange by carnotite. The large deposits of haematite at the Iron Knob, Iron Monarch, Iron Baron, etc., south of Port Augusta in South Australia are of pre-Cambrian age. In the Macdonnell ranges, associated with the pegmatite dykes, are large crystals of muscovite mica, from 12 to 18 inches or more in diameter. Beryls in large crystals, but not of commercial value, occur in the same region. A remarkable rock in the pre-Cambrian group is that known as ribbon jasper. This rock, often many hundreds of yards in width, is typically a beautifully banded haematitic quartz rock. It can be traced for hundreds of miles along the gold-bearing belts of Western Australia as far north as Kimberley goldfield, and wherever reefs of quartz intersect it they are usually gold-bearing. Recent petrological research proves that this ribbon jasper is, in places, a mylonized quartz-dolerite, subsequently altered by silicification. It is singular that in other places (as at Boulder, near Kalgoorlie) a similar mylonized quartz-dolerite has been converted into a graphite-schist, possibly as the result of long-continued emanations of methane, which gas is still being evolved from the gold-telluride-bearing graphite-schists at the Great Boulder Proprietary mine. At Bimbowrie in South Australia magnificent crystals of chiastolite, used for jewellery, are abundantly developed in the pre-Cambrian rocks. To the east of the Mount Lofty ranges in South Australia there is a considerable development of andalusite-bearing schists, with which are associated schistose diopside-diorite. The latter rock is very rich in ilmenite, and black sands derived from this ilmenite are plentifully distributed throughout the basalt rocks of the succeeding Adelaide series. Pre-Cambrian rocks are also well developed in Eyre's Peninsula, where a series of dolomite limestones—the Hutchinson series—are intruded by granite-gneisses with pronounced contact metamorphic effects. The Willyama series of Broken Hill, consisting of sillimanite-garnet-gneisses and schists, granite-gneisses with amphibolite, and pegmatic dykes, is probably Archaeozoic. The Adelaide series (possibly lower Cambrian, probably Proterozoic) is remarkable for the development on a grand scale of glacial tillite. It has now been demonstrated that these glacial beds are in places fully 1000 feet in thickness, extend from the Sturt Gorge (east of Adelaide) at least as far north as Pekina (north of Port Augusta) and may extend almost to the tropic of Capricorn near Lake Eyre. The glacial beds of South Australia cross into New South Wales in the Barrier ranges about 20 miles north of Broken Hill. These beds are met with about half-way up in the 10,000 feet of strata of the Adelaide series.

Cambrian System.—Rocks of this age are developed on a grand scale in the northern part of the Northern Territory, as well as between Lake Eyre and Kangaroo Island. In the Northern Territory, in Arnhem Land, and in the Barkly tableland, the Cambrian rocks—there largely formed of limestones—have proved invaluable as a source of supply of sub-artesian water. These limestones at the Daly River in the Northern Territory (as well as at Mount Panton in the Kimberley goldfield) are rich in the fossil pteropod *Salterella bardmani*. Their thickness is certainly several thousands of feet, possibly 7000 feet. In Arnhem Land and at Kimberley these limestones overlie thick sheets of basic lavas, apparently belonging to the Proterozoic Nullagine series. *Archaeocyathinae* limestones are developed on a large scale at Yorke Peninsula, west of Adelaide, as well as near Normanville and the Onkaparinga Valley, whence they extend at least as far north as the Blinman and Ajax mines near Lake Eyre. They contain a rich and exquisitely preserved fossil marine fauna. It may be mentioned that small pieces of similar limestone were discovered in Antarctica by Sir Ernest Shackleton near Mount Darwin, about 360 miles from the south pole. In Tasmania Cambrian rocks (yellow rusty friable sandstones and quartzites) occur at Caroline Creek between Railton and Latrobe, as well as on the Humboldt Divide and in the Florentine Valley. These rocks, which contain well-preserved casts of *Crepicephalus*, are considered to be of upper Cambrian age.

The Heathcotian Series.—Shales and mudstones containing the trilobites *Dinesus* and *Notasaphus*, *Protospongia* and other sponge spicules, brachiopods and radiolaria, occur about three miles north of Heathcote. These were originally referred to the Cambrian, and later to the Ordovician age. Recent evidence tends to reinforce their Cambrian age. Immediately underlying these beds to the east comes a mixed series of black cherts, cherty shales, and igneous rocks—principally basic lavas, described as diabases, tuffs, and agglomerates, with a few minor dioritic intrusions and a larger intrusive mass of micro-granite. To these rocks the term Heathcotian has been applied. They have been described as underlying the *Dinesus* beds with marked unconformity, and have been referred to the pre-Ordovician and even to the pre-Cambrian series. Others have pointed out that there is no evidence of unconformity between them and

the overflowing Ordovicians, but there is evidence of a gradual passage; they cannot, therefore, be older than Cambrian and may be Cambo-Ordovician in age. Similar rocks, with similar stratigraphical relations, and containing black cherts with *Protospongia* and radiolaria interbedded with diabases, occur NE. of Lancefield. Probably the diabases and cherts of Mount Major near Dookie, of Mount Stavely, and of the Hummocks in the west of Victoria, and the tuffaceous series with limestones containing *Crepicephalus* and *Plectorthus* near Mount Wellington in eastern Victoria, are also referable to the Heathcotian series. In Tasmania the Porphyroid series of schistose quartz-porphyries, felsite tuffs and breccias, and spilitic basic rocks, of the Leven Gorge, and the Dundas slates, are presumably of Heathcotian, and therefore perhaps of Cambrian or Cambo-Ordovician age.

Ordovician System.—Two well-marked types—the one littoral, the other probably pelagic—are referred to this system. Shallow-water strata of the former type have been described from Tempe Downs station and the Levi Range, south of the Macdonnell ranges. These rocks show ripple-marks and sun-cracks, as well as cubical pseudomorphs in quartzite after rock-salt. Abundant well-preserved fossils, of which the commonest forms are *Orthis leviensis, Endoceras warburtoni* and *Asaphus illarensis,* are to be found in this neighbourhood in sandy calcareous shales. The other type of Ordovician rock (the dominant type, in fact) consists of black carbonaceous shales and slates, with bands of fine-grained sandstones and quartzites and occasional conglomerates. They are best developed in Victoria, where they are closely folded and strike generally in a NNW. direction. They are divided into a lower series in which the black shales and slates on the whole predominate, and an upper series in which sandstones are more prominent, and containing basal conglomerates, as at Kerrie, E. of Mount Macedon. The lower member has been divided by its graptolite zones from above downward into the Darriwil, Castlemaine, Bendigo, and Lancefield series. The most productive goldfields of Victoria—such as those of Poseidon, and Steiglitz—occur in lower Ordovician rocks, near intrusions of granodiorite. It has been suggested that the quartz reefs are generally most productive where traversing black shales of the Bendigo series. The lower Ordovician rocks have so far only been found in Victoria, and (with the exception of the Mornington Peninsula) only W. of a line running N. from Melbourne and stretching to the western boundary of the State. The upper Ordovician rocks are, on the whole, less closely folded than the lower series; they are also less auriferous, but have a generally similar NNW. strike, and occur only E. of a line running N. from Melbourne. Near Melbourne they occur at Diggers' Rest, and farther north at Kerrie. Inliers of upper Ordovician rocks occur near the Wood's Point goldfield, and also farther E., surrounded by the broad belt of Silurian rocks; while very extensive areas in eastern Victoria have yielded only upper Ordovician graptolites.

Northwards from Victoria the upper Ordovician rocks extend into New South Wales, sweeping in a broad belt E. of Mount Kosciusko, between the Snowy River and Cooma. A belt of the same rock has been identified at Tallong near Marulan. At Cadia near Orange there is a great belt of these rocks, containing contemporaneous andesite lava, with large deposits of iron ore. In Tasmania strata of Ordovician age, of the nature of black slates with very doubtful impressions of graptolites, may possibly be Ordovician.

Silurian System.—Strata of this age appear to be wholly restricted in the Commonwealth to the eastern portion of Australia and to Tasmania. In Tasmania they are well developed in the neighbourhood of the Mount Lyell mine, where they contain the trilobite *Homalonotus.* The strata in Victoria are divided into an upper (Yeringian) and a lower (Melbournian) series. At Lilydale there is a well-preserved marine fauna in the local limestones. These strata are not so strongly folded as those of the Ordovician system. Perhaps the richest fossil-bearing locality for the Silurian is to be found in the Yass district of New South Wales. The rocks there consist of contemporaneous dacite tuffs with sandy shales, olive-coloured to yellowish-brown shales, and numerous beds of limestones, which are built up of a rich coral fauna—obviously old fringing coral-reefs. One of the commonest and most characteristic corals is the mushroom-shaped form, *Mucophyllum. Pentamerus* is plentiful near the limestones in the middle system. *Halysites* is common and characteristic in the lower limestones of the system; at Spring Creek near Orange, and at Molong, it is the sole constituent of some coral-reefs. In the upper strata the trilobites *Hausmannia* and *Encrinurus* occur plentifully. The Jenolan Caves of New South Wales have been hollowed out of limestones rich in *Pentamerus.* In the limestone reefs at Wellington beautifully preserved siliceous sponges allied to *Astylospongia* are weathered out of the surface of the limestone. Silurian rocks so far have been identified in Queensland only in the neighbourhood of Chillagoe, where limestones containing *Halysites* are developed. At the same time it is considered probable that a belt of Silurian extends through Queensland, from the south of Boulia to the extreme north-west, and from 20 miles east of Cloncurry to the western boundary of the State.

Devonian System.—This is the oldest system in the Commonwealth in which definite fossil land-plants have been discovered; they give evidence of a great extension of the land-surface of Australia in an easterly direction since the close of pre-Cambrian time. They occur at intervals all the way round from Kimberley to Cloncurry as well as in the Burdekin basin, the Tamworth area, the region west of the Blue Mountains between Mudgee and Bowenfels (and a parallel strip near Wellington), Spring Creek near Orange, and Canowindra. They are also represented at the Yalwal goldfield, S. of the Illawarra district, as well as on a large scale at Burrinjuck and in the Pambula regions. Outlying patches of Devonian rock occur at Cobar, Oxley's Tableland, Gundabooka Mountain, and White Cliffs beyond Wellington. Southwards they can be traced into Victoria as the Snowy River porphyries, the Buchan and Bindi limestones, and the Tabberabbera shales. No undoubted Devonian rocks have as yet been proved in Tasmania, South Australia, or Western Australia south of Kimberley. The system is divisible into three series, the lower of which is often chiefly volcanic, consisting of banded rhyolites and tuffs associated with reddish-purple to chocolate-coloured shales. In places the volcanic rocks become basic. In the neighbourhood of Burrinjuck and higher up the Murrumbidgee River (near Taemas) there is a splendid development of folded lower or middle Devonian limestones.

A conspicuous and characteristic large fossil in these rocks is the form *Receptaculites*, and remains of large bony-plated fish, such as *Coccosteus* and *Asterolepis*, have been found in them. In Victoria the Buchan and Bindi limestones occupy eroded hollows in the surface of the Snowy River porphyries. The Grampian Range—of white, grey, red, and purple sandstones and conglomerates—perhaps belongs to the upper Devonian beds.

In New South Wales the Devonian is widely distributed, the major structure being a geosyncline which underlies the Permo-Carboniferous coal basin and outcrops along its margin NE. and SW. The numerous inliers and outliers in the western districts of this State have so far not received much attention. The area which has been most closely studied is that of the Tamworth district, where Benson has recognized upper, middle and lower Devonian rocks; the upper Devonian (Barraba) series comprises a thick series of radiolarian mudstones, tuffs and argillaceous limestones, which overlie the wonderful Baldwin agglomerates, in places 2000 feet thick. The middle Devonian comprises an upper group known as the Tamworth series, which contains radiolarian claystones with numerous specimens of *Lepidodendron australe*, and interbedded lenticular masses of coralline limestone—the curious coral *Sandidophyllum* is a dominant type on the Moore Creek horizon; and a lower group represented by a volcanic series containing spilites and dolerites, which overlies radiolarian cherts and claystones with interbedded tuffs. The lower Devonian (Woolomin) series is largely represented by phyllites and jasper beds, with which is interbedded a complex volcanic series. The whole Devonian series of this district probably exceeds 10,000 feet in thickness.

In Queensland the chief development of Devonian rocks is in the Burdekin basin. There they consist of very massive conglomerates at the base, passing upwards into coral-reef limestones of vast thickness (on the Burdekin River they are no less than 7000 feet thick); the most characteristic fossils are *Pachypora meridionalis* and *Stromatoporella*, with which are associated fossil plants such as *Dicranophyllum*, as well as a remarkable undescribed form. *Receptaculites* occurs at Mount Wyatt in Queensland. Upper Devonian rocks are mostly represented by reddish to grey quartzites, sandstones, and red shales. They are typically developed in New South Wales at Mount Lambie, Mount Walker, and Spring Creek near Orange, and are very rich in *Spirifera disjuncta* and *Rhynchonella pleurodon*. Lastly, at Kimberley there is a belt of marine Devonian rocks containing a fauna which suggests that it may be of middle Devonian age.

Carboniferous System.—Excepting, perhaps, the belt of rocks containing traces of rock oil at Kimberley, and the Grampians sandstones in western Victoria—which have yielded forms of *Lingula* and fish remains similar to those of the Mansfield rocks—no rocks of this age are known in Australia W. of a line joining Cape York with Melbourne. No trace of *Lepidodendron* has as yet been found in Tasmania. The system is widely represented in Queensland, where many of the folded highlands of the north-eastern coast ranges are built up of these rocks. The latest folding to which the earth's crust in Australia has been subjected belongs to late Carboniferous time. So far no marked unconformity has been traced between the Devonian and Carboniferous rocks. Rocks of true Carboniferous age in the Commonwealth are characterized by the presence in their lower strata of *Lepidodendron volkmannianum, L. veltheimianum* and *L. dichotomum*, and in their upper portion by several species of *Rhachopteris* and *Aneimites*. So far no single example of a *Lepidodendron* has been found anywhere in the Commonwealth in rocks of the so-called Permo-Carboniferous age, except in the Kimberley area of Western Australia. A marine fauna is associated with this system, particularly in its lower and middle portions. Important forms to distinguish Carboniferous rocks from the Devonian on the one hand, and the Permo-Carboniferous on the other, are *Phillipsia* and *Syringothyris*. So far no trace of trilobites has ever been observed in any of the true Permo-Carboniferous rocks. *Michelinia* and *Lithostrotion*, found in New England, are essentially Carboniferous forms, which never ascend into the Permo-Carboniferous systems. Less reliance can be placed on the brachiopods, many of which (such as *Productus semireticulatus, Orthis, Streptorhynchus*, etc.) ascend into the Permo-Carboniferous system.

The middle and partly upper Carboniferous (Kuttung) series is characterized by a vast thickness of lavas and tuffs, mostly acidic, such as rhyolites and ceratophyres associated with hypersthene andesites, hornblende andesites, and magnetite-sandstones. Intrusions of granite and quartz-porphyries occur on a grand scale in this system, and it may be assumed that the rhyolites and other acid lavas are the volcanic representatives of the granite batholiths. As regards local development, Carboniferous strata formed of reddish shales and sandstones are most typically developed in Victoria near Mansfield. They there contain *Lepidodendron veltheimianum*, with an abundance of fossil fish such as *Gyracanthides murrayi, Acanthodes australis, Eupleurogamus cresswelli, Strepsodus decipiens, Ctenodus breviceps, Elonichthys sweeti* and *E. gibbus*. The occurence of *Lepidodendron australe* in beds of undoubted Carboniferous age in the Star series of Queensland suggests that this widely developed series is, in part, upper Devonian; but the marine fauna is mostly lower Carboniferous.

In New South Wales the Carboniferous system, about 20,000 feet in thickness, extends in a wide folded belt from Port Stephens northwards into New England, reaching the Queensland border near the Horton River. It is best represented in the Hunter River district, where upper, lower and middle Carboniferous are recognized. The lower Carboniferous (Burindi) series consists chiefly of a thick series of marine mudstones, with some limestones and conglomerate, and a volcanic series. An abundant marine fauna is represented on certain horizons, and plant-remains such as *Lepidodendron, Ulodendron, Cyclostigma, Archaeocalamites* and *Pitys* also occur.

The middle Carboniferous (Kuttung) series is one of the most interesting and important in Australia. It consists of a thick volcanic series, interbedded with which are varve shales and true glacial tillites. The volcanic series is represented by hypersthene andesites, pitchstones and rhyolites, and tuff beds of similar character. In the Currabubula district the Kuttung series is intruded by sills of andesite, dolerite and ceratophyre. The chief interest, however, attaches to the glacial beds, for these are of

widespread occurrence throughout Australia. In the Hunter River district a wonderful series of varve shales occurs, interbedded with the volcanic series; these are often strongly contorted, and exhibit remarkable miniature folds. At Seaham tillite containing ice-striated boulders occurs on three horizons, which are interbedded with the varve shales. The lowest tillite bed is 200 feet thick. The whole glacial series is here about 1890 feet thick, a little more than half consisting of glacial deposits, and the remainder of tuffs and tuffaceous mudstones. At Webber's Creek (between Gosforth and Paterson) a striated pavement underlying varve shales has been discovered. The striations clearly show that the ice moved in a northerly direction. In Victoria there is a wonderful development of glacial beds of the nature of tillites, associated with contemporaneous conglomerates and ripple-marked sandstones, together with fine clay shales. These glacial beds lie on a surface of low relief, though in places (as at the Werribee gorge) the tillite fills an old U-shaped valley—perhaps an over-deepened valley. The rocks on which the tillite rests, mostly of Ordovician age with post-Ordovician granites, are very strongly striated and grooved by ice coming from a southerly direction. The sandstone beds between the tillites show strong evidence in places of contemporaneous contortion. As the matrix of the tillite varies with that of the subjacent rock, there can be no doubt that the tillite was formed by an immense sheet of land ice, the main mass of which lay to the south. These glacial deposits can be traced at intervals across Victoria northwards by way of Heathcote to Beechworth, close to the southern border of New South Wales; fine striated pavements can be seen at Derrinal, near Heathcote, together with erratics up to 30 tons in weight. Westwards they extend under the level plains of Tertiary rock, having been proved to underlie Nhill. To the south of Adelaide, between that city and the mouth of the Murray River, there are magnificent cliff sections showing the junction of the old glacial beds with the lower Cambrian strata. Beautiful striated pavements are to be seen in the Inman Valley, at Hallett's Cove, etc., which prove that the ice came from a south by east direction. The glacial beds are there, with their associated conglomerates, sandstones and shales, fully 900 feet in thickness. At Mount Grainger and Booleamatta there is an enormous development of these beds, possibly exceeding 5000 feet in thickness. So far, in South Australia as in Victoria, no productive coal or marine fossils have as yet been found over-lying these beds. In fact, there are considerable patches there of Kuttung glacial landscape rediscovered by modern denudation. In Tasmania the glacial series has a thickness of about 800 feet. Splendid sections can be seen between tides on the beach E. of Wynyard. Several striated pavements in the tillite show that the ice moved from SSW. to NNE. An interesting fact which has lately come to light is that there are at least three—perhaps four—distinct tillite horizons, separated from one another by strata perhaps representing interglacial epochs. Each tillite horizon can be correlated certainly with those of Victoria, and almost certainly with those of South Africa.

In Western Australia glacial tillite occurs on a large scale at the base of the Irwin River coal-field, and the glacial conglomerate has been traced from near the Carnarvon bore (at the mouth of the Gascoyne River) to the Wooramel River, and almost up to the latitude of North-west Cape. Thus in Western Australia these glacial beds actually touch the region of the tropics. As evidenced by the nature of the contained boulders, when compared with their nearest parent rocks, it is clear that the ice-sheets which produced this glaciation moved, on the whole, from the inland plateau westwards or northwards—probably in a north-westerly direction, inasmuch as the glacial boulders become progressively larger the farther south they are traced. These glacial beds are known as the 'Lyons conglomerate.' So far no striated floor has been discovered beneath them.

To sum up: (*a*) In regard to Palaeogeography the ice which glaciated Tasmania, Victoria and South Australia came from the south, from a land which was probably a local extension of the Australian continent into the Southern Ocean. The glaciation of Cambrian time in Australia came from the same quarter. In Western Australia the glaciation is thought to have come from the south-east, from local highlands near the southern end of the State. In eastern Australia the region affected by the glaciation was a landscape apparently of low relief, but we know nothing of the height of the gathering-ground of the ice-sheets on the now sunken part of the continent, where the eastern end of Jeffrey's Deep shows a depth of 3000 fathoms. Possibly the large bank recently discovered, which lies about 200 miles south of Tasmania and rises from great ocean depths to within 500 to 600 fathoms of the surface, formed part of a high south-eastern margin to Australia, extending in Carboniferous time from this bank to Kangaroo Island. In New South Wales there seem to have been local alpine glaciers. In the south-western region of Western Australia there seems to have been a local ice-sheet. (*b*) There were at least three interglacial phases in Australia, probably to be correlated with those of Africa. (*c*) The fauna, especially because of the disappearance of lower Carboniferous reef-forming corals, suggests glacial refrigeration of the seas, while the flora of the coal-seams is not inconsistent with that of a climate like that of Macquarie Island. (*d*) In Carboniferous time the snow-line touched sea-level probably near 40° S. lat., and glaciers came down to sea-level at about 34° S. lat. (*e*) This may indicate a fall of temperature, as compared with the present, of about 10° C.

The upper Carboniferous is represented by a marine series, forming that lower portion of the lower marine series of the so-called Permo-Carboniferous system which includes the *Eurydesma cordata* horizon, and extends downwards to the Brandon conglomerate. Considerable economic interest may attach to the Carboniferous rocks of the Kimberley region on account of the recent discovery of traces of rock oil in them at Price's Creek ESE. of Geikie Canyon on the Fitzroy River, and of asphalt glance in the vesicular basalts at the junction of the Ord and Negri rivers, near the north-western boundary of the Northern Territory.

Permo-Carboniferous (*Permian*) *System.*—Of all the sedimentary formations developed in the Commonwealth this system is perhaps the most interesting. The interest depends, in the first place, on the remarkable development of the *Glossopteris* and *Gangamopteris* flora, which replaced everywhere within the Commonwealth the *Lepidodendron* flora of the preceding system; and, in the second place, on its marine fauna,

which belongs to two sharply differentiated types —the western, allied to the Permo-Carboniferous fauna of India, and the eastern, a distinct fauna in many respects unlike any developed in other parts of the world. Furthermore, probably nowhere else in the world are Permo-Carboniferous strata of such thickness, or so rich in diversified forms of animal life.

In regard to the upward passage from the Carboniferous strata into the Permo-Carboniferous, while there is little evidence of unconformity in some places, in others (e.g. near Lochinvar in the Hunter valley of New South Wales) the unconformity is fairly strongly marked. At the same time it is not nearly as strong as that developed in the British Isles between the Permian dolomitic breccias and the Carboniferous rocks.

While the Carboniferous strata in the Commonwealth are mostly disposed in fairly close folds, the Permo-Carboniferous strata are either perfectly horizontal or disposed in broad open troughs and arches. Only at Drake, Undercliff and Ashford in New South Wales, and at Gympie in Queensland, are the strata of this system highly disturbed near granitic intrusions.

The term 'Permo-Carboniferous,' in view of the present state of our knowledge, is somewhat of a misnomer. It was applied, in the first case, by R. L. Jack and R. Etheridge, junior, to certain strata in Queensland, which undoubtedly did include forms of life (chiefly marine) that were characteristic partly of the Carboniferous, partly of the Permian age. It is now known that in Queensland these rocks can be sharply divided into two groups—an older, in which *Lepidodendron* and *Phillipsia* are present, and a younger, which lacks them but contains a marine fauna distinctly comparable with that of the Hunter River region of New South Wales. In spite of the fact that some of the brachiopods of this Permo-Carboniferous system show affinities with those of the Carboniferous, it appears to the writer that there is no longer need for the retention of the term Permo-Carboniferous, but that the strata of this system should be considered to be mostly Permian. In parts of Western Australia where Permo-Carboniferous rocks are developed (as at the Gascoyne, Wooramel, and Minilya rivers) a well-marked glacial horizon, the 'Lyons conglomerate,' underlies the bulk of the Permo-Carboniferous strata. There is now little doubt that this glacial horizon is identical with that of Bacchus Marsh in Victoria, Hallett's Cove in South Australia, Wynyard in Tasmania, and Lochinvar and Kempsey in New South Wales. All the strata above this glacial horizon might fairly be termed Permo-Carboniferous at any rate, if not Permian, the main glacial horizon being referred to the Carboniferous. In the Kimberley district of Western Australia the glacial horizon has not been identified definitely—and perhaps does not exist there; but the fossils are essentially similar to those above the horizon of the Lyons conglomerate, and may therefore provisionally be classed as Permo-Carboniferous and even Permian. While, therefore, considering that there is much to justify the use of the term 'Permian,' the writer proposes to retain for the purposes of this article the old term 'Permo-Carboniferous,' chiefly because it has been so widely used and generally accepted.

Rocks of this system are very widely spread throughout the Commonwealth. In Tasmania about one-half of the island (which is rather bigger than Ceylon, but smaller than Ireland) is covered with rocks of this age. Here the tillite beds of the Wynyard series, which are of Kuttung (middle to upper Carboniferous) age, are succeeded by marine strata belonging to the lower marine series, over 600 feet thick at this locality. This series is followed by one of the most important coal-bearing horizons in Australia, the Greta series, represented in Tasmania by only a few seams of coal, from 20 inches up to 3½ feet in thickness; in places this coal passes into kerosene shale, formed largely of the problematical plant considered to be an alga, *Reinschia australis*. Above the Greta series in Tasmania is a considerable development of rocks of the upper marine series; the great series of freshwater coal-measures developed in New South Wales and Queensland above the upper marine series are wanting, and rocks of Trias-Jura or Jurassic age rest conformably on the topmast marine beds of the Permo-Carboniferous system.

In Victoria the whole series of Kuttung glacial beds passes upwards into sandstones containing *Gangamopteris*, and is over 2000 feet in thickness; no marine strata or coal-seams have been hitherto discovered. Still farther west, in the south-western corner of Western Australia, a small basin preserved in a deep trough-fault is known as the Collie coal-field; it contains *Glossopteris* and *Gangamopteris*, associated with numerous seams of coal up to over ten feet in thickness. The strata are water-bearing between the seams, but fortunately the roofs of the seams are impervious. The percentage of ash is only from about six to eight per cent, and there is from 30 to 40 feet, in the aggregate, of workable coal. The coal itself, contrary to our usual experience in strata of this age, is distinctly hydrous. Northwards from Perth the Irwin River region has preserved a small patch of glacial beds immediately underlying richly fossiliferous marine strata that include limestones, conformably overlying brown clay shales. Two seams of coal conformably overlie the marine strata; the main seam is five feet thick and, though not so proved by fossils, presumably of Permo-Carboniferous age. In the Kimberley district of Western Australia there is a considerable development of marine Permo-Carboniferous calcareous sandstones and limestones; it has been proved that from the Gascoyne River to the Kimberley district these Carboniferous strata contain invaluable supplies of artesian water, though (strange to say) they are quite wanting, as far as they have yet been tested, in productive coal-seams. Strata of this age extend farther east round the Australian coast to the Victoria River, where the marine strata are associated with freshwater shales containing *Glossopteris*. This *Glossopteris* underlies strata that contain *Orthotetes* and *Aulosteges*. The formation has been traced into Arnhem Land (NE. of Darwin), and to the islands off the north-eastern extremity of Arnhem Land. Groote Island is thought to belong to this system. A remarkable feature is that, from the Gulf of Carpentaria round to the Irwin River region, the whole assemblage of marine Permo-Carboniferous fossils is distinctly of Indian type. SSE. of Cape York is a deep indent in the coast-line marking a prolongation of the trough-valley in which lies the Permo-Carboniferous coal-field of the Little River. As the result of heavy downthrows the strata have been forced into rather sharp zigzag folds, a rare structure in rocks of this age in

Australia. Coal of good quality is worked at Mount Mulligan, W. of Cairns. Near Townsville is a small development of Permo-Carboniferous strata, which there underlie the coastal plain, and extend out to sea beneath the reefs of the Great Barrier. Next we reach the classical coal-field of the Bowen River. There evidence of glacial action, in the form probably of floating ice, is to be found in the shape of numerous small boulders of granite and other rocks foreign to the district, embedded in the clay shales of the Permo-Carboniferous system; but nothing approaching a true tillite has ever been observed in this area. Next, on the south, come the extensive and thick coal-seams of the Dawson River basin. The thickest seam known in Australia in rocks of this system occurs at Blair Athol, where the main seam is at least up to 93 feet thick. Steam coal of good quality occurs in a seam 11 feet thick on the Dawson River, about 30 miles south of Duaringa, but unfortunately the coal-field in that area is much broken up by faults. The Permo-Carboniferous system in this important coal-field can be divided into the following groups, which are arranged in ascending order:—(*a*) Marine beds such as those of Gympie, with boulders presumably transported by ice. (*b*) Lower marine strata, followed by a volcanic series. (*c*) Freshwater strata, with the 11-ft. seam of steam-coal already described. (*d*) The marine shell beds of Oakey Creek and St. Mary's, capped by the *Glossopteris* beds of Oakey Creek and St. Mary's. All these strata are grouped together as Lower Bowen. There follows a slight unconformity, and above it are developed the marine shell beds of Claremont and Capella. Above these again, and slightly unconformable to them, are the Tolmies and Blair Athol coal-measures, the latter capped by the old auriferous conglomerates of Claremont. The whole of this last series is grouped together as Upper Bowen. No estimate has, as yet, been formed of the available quantity of Permo-Carboniferous coal in Queensland, but it must be very vast—perhaps approximating to the 100,000,000,000 tons roughly estimated to be present in the form of exploitable coal in New South Wales.

South-east of the Dawson field the Permo-Carboniferous strata are represented by the basal marine beds of the Gympie goldfield. Wherever the quartz reefs which traverse these strata come in contact with the occasionally intercalated beds of black carbonaceous shale, they are payably gold-bearing. The Dawson coal-field, traced in a southerly direction, reaches the borders of New South Wales near Bonshaw and Ashford; at the latter place a fine seam of steam coal, 27 feet thick, is to be seen in the left bank of the Severn River. As *Gangamopteris* is the only fossil known to occur in association with this seam, it may provisionally be considered of Greta age. This field occupies a narrow fault-trough. About 100 miles east of this spot, at Undercliff, there are beds of graphite associated with intrusive acid granites, which are considered to represent intensely metamorphosed coal-seams of Permo-Carboniferous age. These graphitic strata are to be connected with marine beds of undoubted Permo-Carboniferous origin, as at the goldfield of Drake, where contemporaneous acid and basic lavas are inter-stratified with the lower beds. The Permo-Carboniferous strata at Drake have been recently traced in Queensland near Silverwood, southerly from Warwick; upper and lower marine beds, and either Newcastle or Greta coal-measures, are developed there, and are much crushed and folded. The newest acid granite intrudes part of this series if not all of it.

South from Ashford the region of Gunnedah is reached, from which the principal coal-field of New South Wales extends without a break for fully 300 miles, as far south as the head of the Clyde River near Ulladulla. The type-district in this field is that of Maitland in the Hunter valley, where the Permo-Carboniferous series is ushered in by marine passage beds, tuffaceous shales and a flow of natrolite basalt, followed by *Eurydesma cordata* beds, above which is a thick series of beds forming the upper portion of the lower marine series. The Greta coal-measures, from 100 to 300 feet thick, which conformably overlie the lower marine series, are not relatively rich in fossil plants. It is significant that in them *Gangamopteris* predominates over *Glossopteris*, whereas in the higher coal-measures of this system the reverse is the case. *Gangamopteris* has been found as low down as 2000 feet below the Greta coal-measures, in the middle of the lower marine series. The Greta coal-measures usually contain about 20 feet of workable coal—and, exceptionally, as much as 40 feet. The upper marine strata, which follow the Greta, attain the maximum thickness yet proved in the Hunter River region, 5000 to 6400 feet. About half-way up in the series erratics, certainly of glacial origin, are very numerous in places, occurring usually in groups; many are from one to two tons in weight, and appear to have been derived from the region of Mount Lambie, near Rydal or Bathurst, about 200 miles SW. It is significant, probably, of glacial conditions that we find an almost total absence of reef-forming corals in the Permo-Carboniferous strata; such corals as do occur are small dendroid types, like *Zaphrentis* and *Trachypora*. Near the top of the upper marine series, as well as on certain horizons lower down, are remarkably large pseudomorphs known as glendonite. These crystals attain a length of from two inches to one foot. They are best seen on the beach between tide-marks at Huskisson on Jervis Bay, about 100 miles S. of Sydney, where the shore presents the appearance of a medieval battlefield, strewn with spear-heads and caltrops. They are pseudomorphs after the double sulphate of sodium and calcium, glauberite. As deposits of sodium sulphate are very common and characteristic in Antarctica, these glendonites may have some climatological significance. They have also been found in Tasmania, close to the horizon of the oil shale known as Tasmanite, in part of the Mersey coal-basin. Above the upper marine follow the strata of the middle coal-measures (East Maitland or Tomago). These are from 500 to 1800 feet thick, and contain in the aggregate about 40 feet of coal, which, being more friable than that of the Greta, is not so suitable for export though useful for household, gas, and blacksmithing purposes. A total thickness of about 18 feet of coal is worked. In parts of the Hunter River coal-field there follows a considerable thickness (in places about 2000 feet) of freshwater strata, with abundant plant remains, but devoid of any coal-seams of workable thickness. These beds belong to the Dempsey series. Above the Dempsey comes the Newcastle series, 1200 to 1400 feet in thickness, with about 120 feet of coal. The thickness of the seams varies from one foot up to about 27 feet, and the aggregate thickness of workable coal from 35 to 40 feet. At Awaba on the

shores of Lake Macquarie, as well as at the lake's southern entrance (Reid's Mistake), are fossil forests of coniferous trees. At the latter locality it can be seen that the trees sprang directly from the upper portion of a coal-seam, being actually in position of growth. The lower parts of the stem are of carbon; upwards they pass into chalcedony, where they have been buried under showers of very fine volcanic tuff. The tuff has evidently broken down branches of the trees, and resin has exuded from the fractures, and is preserved now in the form of black drops in the tuff, the latter being converted into chert. Some of these coniferous trees can be seen to be over 100 feet in length.

On the whole the evidence favours the view that most of the coal-seams of the Permo-Carboniferous system were formed at the spot where seams are now found. In the underclay only thin rootlets have been observed; in the clay bands higher up in the seam, numerous specimens of *Vertebraria* can be frequently seen in position of growth; and only in the actual roofs of the seams have forest trees like the conifer *Dadoxylon* been proved to exist. In places (but rarely) remains of fossil fish and of labyrinthodonts have been discovered in the coal-measures, from those of Greta age up to those of Newcastle age. A small labyrinthodont has been recorded from the Mersey coal-measures (Greta horizon) near Railton; another (*Bothriceps*) was found in the kerosene shale at Airlie, in the western coal-field of New South Wales. *Palaeoniscus* has been obtained from the marine (probably lower marine) Permo-Carboniferous rocks of Tasmania, and *Urosthenes* from the Newcastle coal-measures of New South Wales. The upper coal-measures of the Newcastle series have yielded numbers of the phyllopod *Leaia mitchelli* and some very interesting fossil insects of the holometabolous type which have not elsewhere been found in Palaeozoic rocks. The total amount of exploitable coal in these measures in New South Wales, in seams not less than three feet thick and not more than 4000 feet in depth, is estimated to be roughly about 100,000,000,000 tons.

Trias System.—Rocks of this age are at present known chiefly in the Sydney and Blue Mountain areas of New South Wales. In Tasmania, however, the Knocklofty series—variegated sandstones, 1000 feet thick, which in the neighbourhood of Hobart overlie the Permo-Carboniferous strata—have been doubtfully referred to some part of Triassic time. They contain remains of *Acrolepis hamiltoni* and *A. tasmanicus*, and bones of a labyrinthodont. The occurrence in the sandstones of *Vertebraria indica* suggests affinities with the Permo-Carboniferous system. The Ida Bay series, containing *Zeugophyllites* and *Pecopteris lunensis*, is perhaps Triassic. In regard to the Fingal series in the Tasmanian coal-measures, as some doubt exists as to whether they belong to the top of the Trias or to the base of the Jurassic, they will be described later. The Triassic strata of New South Wales extend along the coast from the Cambewarra Range in the south to Lake Macquarie near Newcastle in the north; thence they stretch NW. to beyond Gunnedah, and W. to a little beyond Lithgow. The rocks in this area have been divided (chiefly lithologically) into three stages which, in descending order, are as follows:—upper Triassic, Wianamatta shales—thickness about 800 feet; lower Triassic, Hawkesbury sandstone, thickness about 300 to 1000 feet; Narrabeen beds, thickness about 200 to 2000 feet.

The strata of the Narrabeen stage are largely tuffaceous, but the true tuffs do not constitute more than about one-tenth part of the whole thickness. In their lower portion they are mostly grey to greenish-grey sandstones, with greenish conglomerates and grey-green and reddish to chocolate-coloured shales. Bands of blackish-grey shale are crowded with remains of *Estheria Coghlani* and other species of this genus. Five hundred feet above the Bulli coal-seam (the top of the Permo-Carboniferous system) tuffaceous red shales and green tuffs contain innumerable small scales of metallic copper, together with microscopic veins of the same metal; these strata are known as the cupriferous tuffs. Over 1000 feet above these tuffs is a second series of green tuffs and chocolate-red shales. In the latter at Long Reef, 12 miles NE. of Sydney, beautiful examples occur of plants resembling *Phyllotheca*, with their stems of brittle bituminous coal, held together in a delicate filigree-like network of metallic copper. Where the strata have been much weathered, the metallic copper passes into green and blue carbonates. The copper has obviously been derived from the decomposition of the basic tuffs. The tuffs are traversed in places by small veins of barytes.

The Hawkesbury sandstone, which is typically developed at Sydney and in the Blue Mountains, is chiefly formed of white to yellowish-grey sandstones, very regularly and evenly bedded, diagonal bedding being very conspicuous. South of the Hawkesbury River, in the area where this diagonal bedding dips NE., primary graphite is scattered in scales or small pellets through the sandstone. North of the Hawkesbury the diagonal bedding dips in almost the opposite direction—that is from off the New England tableland—and this part of the formation does not contain graphite. Small garnets are not infrequent in the southern type of Hawkesbury sandstone. Certain beds in this stage form a valuable building stone, largely worked in Sydney and suburbs, which as the result of chemical changes in the iron carbonates weathers to a pleasing tint of warm sepia. A few bands of dark clay shale, interstratified with the sandstone, often show evidence of having been disrupted contemporaneously, the fragments being upended so that their lamination planes are now vertical. Neither the sandstones above nor those below show any signs of disturbance. This phenomenon, together with that of contemporaneously contorted current-bedding, has been ascribed to the action of ice; but other explanations, such as that of undercutting of the clay shales by stream action, are possible. As the result of the removal by capillarity of soluble mineral cement from the inner portion of the sandstone, and its transference to the exterior, these sandstones weather into picturesque shelter caves. The Wianamatta stage is formed of black carbonaceous shales, with at least one seam of coal, which with its clay bands is about four feet thick. The upper half of this stage is sandy and calcareous, ending in a calcareous tuffaceous rock, 100 feet thick, containing a very interesting foraminiferal and ostracodan fauna.

As regards fossil plants, *Thinnfeldia odontopteroides* is specially characteristic and abundant throughout the whole series. *Macrotaeniopteris* and *Phyllotheca* are also typical. *Sphenopteris* is also common, and in places is associated with *Alethopteris* (*Cladophlebis*), but this

last genus is much more characteristic, in Australia, of the Jurassic rocks than of the Triassic. Near the base of the Narrabeen stage beautifully preserved specimens of *Schizoneura* are fairly common; and the genus not only extends downwards into the strata which form the roof over the Bulli coal-seam, but at the Sydney harbour collieries shaft at Balmain has been found associated in a bed of clay shale with *Glossopteris*. *Schizoncura* has never been found in either the Hawkesbury or in the Wianamatta stages, but occurs in Victoria in strata conformably overlying the *Gangamopteris* sandstones and glacial beds at Bacchus Marsh.

Stems of trees are numerous in the tuff beds near the top of the stage, as well as forms allied to *Baiera*. Fossil fruit are plentiful in these beds at Long Reef and Narrabeen, N. of Sydney. Reference has already been made to the abundance of *Phyllotheca*, some stems of which are partly encrusted with metallic copper. Just at the top of the Narrabeen stage, or possibly a few feet up into the Hawkesbury sandstone stage, is a bed of shale at Gosford which has proved remarkably rich in remains of fossil fish and small labyrinthodonts; the principal forms found are *Palaeoniscus, Myriolepis, Cleithrolepis, Apateolepis, Dictyopyge, Belonorhynchus, Semionotus, Pristisomus, Pholidophorus*, etc.

In the Hawkesbury sandstone stage a problematical fossil plant, *Ottelia praeterita*, occurs sparingly. In the occasional intercalated shale beds *Oleandridium* has been recorded, while *Thinnfeldia odontopteroides* is very abundant. The leaves are well preserved, and sufficiently coherent and flexible to be lifted off the surface of the shale; when subsequently examined under the microscope, they are seen to have preserved much original structure. At Biloela (Cockatoo Island) near Sydney a thoracic plate of *Mastodonsaurus* was found, and at the same spot (strange to say) a specimen of *Trematonotus*. This Silurian genus on a Triassic horizon suggests that the fossil may be an erratic in this formation. It is preserved in ironstone, which may have replaced a small fragment of limestone. In shales of the Wianamatta series most of the fossils are either at the base or near the top of the stage. Just as the Hawkesbury sandstone usually rests on an eroded surface of Narrabeen beds, as at the junction line of the Wianamatta shales with the Hawkesbury sandstone, there is in many cases evidence of contemporaneous erosion. A good deal of concretionary clay ironstone has formed in the basal beds of the Wianamatta shales, and these are mostly fossiliferous. In addition to *Thinnfeldia* and *Phyllotheca, Cycadopteris scotopendrina* has been recorded from these beds. True cycads appear on the whole to be wanting throughout the Australian Triassic rocks.

In the ironstone concretions referred to above shells of mollusca are often very abundant, belonging to the genera *Unio* and *Unionella*. The dwarf character of these shells suggests that the strata containing them were deposited in brackish water. In the brick-pits of Newtown and Enmore (Sydney) numerous well-preserved specimens of fossil fish have been obtained, ranging from a few inches up to six feet in length.

Labyrinthodont remains have been found on this horizon both at Enmore and at the 'Gib' tunnel near Bowral. The specimen discovered at the former locality measures 12 feet in length. Its immense jaws are furnished with rows of smaller conical teeth and relatively large tusk-like teeth. A perfect cast of the brain is to be seen in this unique specimen. The original specimen, preserved in clay ironstone, has never yet been described. It is now at Brisbane, in the possession of the government geologist of Queensland, who has presented it for descriptive purposes to the Australian National Research Council.

The Wianamatta stage closes with the bed of greenish tuffaceous and calcareous sandstone, passing into sandy limestone, largely formed of foraminiferal and ostracodan shells. Comment has been made on the fact that in this horizon of the Wianamatta stage we have a remarkable example of the survival of a Silurian type of ostracod in the genera *Beyrichia* and *Endothyra*; also on this horizon is an interesting survivor from the Carboniferous fauna. On the other hand the genus *Haplophragmium*, which also occurs on this horizon, is not known elsewhere to descend so low stratigraphically. The Wianamatta beds have also yielded an insect fauna from a quarry at St. Peter's. The Coleoptera are the most abundant, but representatives of the Blattoidea and Protorthoptera were also found. This fauna has affinities with that of the Ipswich beds, which are also of Triassic age.

The geographical conditions under which the strata of the Hawkesbury series were accumulated appear to be those of a large shallow lake close to the sea, with which possibly there was intermittent communication. The *Gangamopteris-Glossopteris* flora of the Permo-Carboniferous ice age had (with the exception of *Phyllotheca, Sphenopteris*, and perhaps *Alethopteris*) completely disappeared before the earliest strata were deposited in this great lake-basin. Eruptions, perhaps of the Kiama-Cambewarra region, and at all events of that zone, were prolonged into Triassic time, as is proved by the frequent beds of basic tuff in the Narrabeen stage. The evidence of ripple-marks and suncracks on many horizons all through the series points obviously to shallow-water conditions. The foraminiferal ostracodan sandy limestone and calcareous sandstone at the top of the whole series prove that, after a subsidence near the centre of the basin of about 3500 feet, marine (or at least estuarine) conditions supervened. The flora of these Triassic rocks differs from the Jurassic by the presence in the former of *Phyllotheca* in vast numbers, and of *Oleandridium*, while *Taeniopteris daintreei* and the varieties of cycads so common in the Australian Jurassic rocks are wanting in the Trias. Triassic types of *Estheria* do not descend into the Jurassic, neither do the labyrinthodonts.

Endothyra, Beyrichia, Trematonotus (?), and *Palaeoniscus* all represent Palaeozoic forms of life surviving into Mesozoic time. The Clarence series of New South Wales is now considered to be the equivalent probably of the Hawkesbury series, the upper, middle and lower Clarence stages corresponding respectively to the Wianamatta shales, Hawkesbury sandstone and Narrabeen stage. Productive coal-seams occur in the lower Clarence beds up to over 30 feet thick, but most of them contain many clay bands.

It is doubtful whether the Fingal series and other representatives of the upper coal-measures of Tasmania are to be classed as upper Trias (perhaps Rhaetic) or lower Jurassic. As *Taeniopteris daintreei* (*T. spatulata*), regarded in Australia as a critical form for differentiating the Jurassic from the Trias, has never yet been found in Tasmania, and the genus *Phyllotheca* is of common occurrence in these Tasmanian

asset edges, or foliation of rocks

Volcanic Foci

n are specified as such

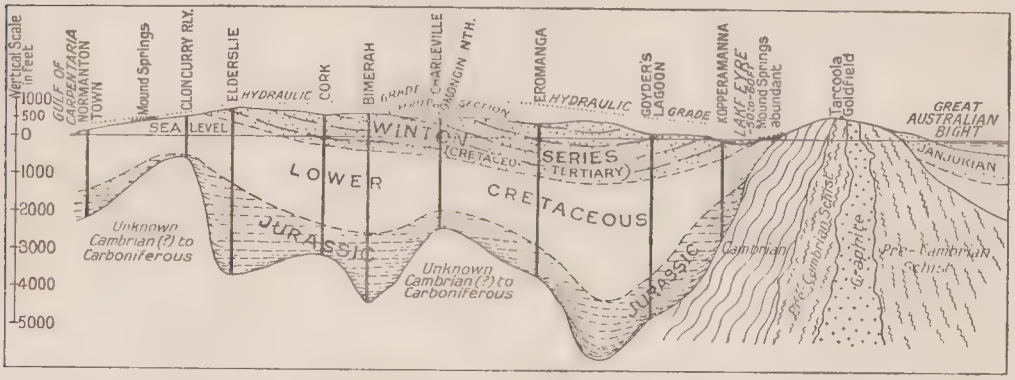
coal-measures, it is proposed to class them provisionally as upper Trias, or passage beds into the Jurassic proper. *Thinnfeldia odontopteroides, Alethopteris australis* (*Cladophlebis denticulata*), *Taeniopteris tasmanica, T. morrisiana, Phyllotheca,* and *Zeugophyllites elongatus* (*Phaenicopsis,* or *Podozamites*) are most characteristic. Other forms present are *Ptilophyllum oligoneurum, Sphenopteris lobifolia, Pterophyllum, Baiera tenuifolia, Ginkgophyllum australe,* etc. It may be stated generally that the Fingal coal-measures are not as rich in fossil cycadaceous forms as are the true Jurassic rocks of the mainland. These measures, about 1200 feet thick, are formed chiefly of yellow, brown, greenish, and bluish-grey sandstones, with coal-seams from four feet up to 20 feet in thickness. The coal is of fair quality, containing from one per cent up to four per cent of moisture, and from nine per cent up to 15 per cent of ash.

In Queensland the Triassic is represented by the Ipswich series and the Bundamba series that overlies it. The Ipswich beds are now thought to be the equivalent of the Narrabeen shales of New South Wales. They consist of grey-coloured to red shales and sandstones with some interbedded conglomerates. Some 14 or 15 coal-seams are interbedded with the series; the coals are chiefly steam coals, and are suitable for the manufacture of coke. The Ipswich beds have a limited extent, and in the type-district near Ipswich attain a thickness of about 2500 feet. An abundant fossil flora has been recorded, of which the chief types are *Neocalamites hoerensis. Cladophlebis australis, Thinnfeldia* (3 species), *Taeniopteris tenison-woodsi, Stenopteris elongata, Ginkgo, Baiera* and *Pterophyllum.* A phyllopod (*Estheria mangaliensis*) is also recorded. At Denmark Hill a rich insect fauna was collected by Dunstan, and has been described by Tillyard; the insects include representatives of many distinct orders, and a large proportion of the species are new. This insect fauna contains types such as *Austromylacrites, Mesorthopteron,* and *Mesomantidion,* and a true hemipteroid, probably to be referred to the Protohemiptera; they are characteristic of the late Palaeozoic of the northern hemisphere. Other types include a true dragonfly (probably an anisopterid) and a panorpid (Mecoptera). This fauna is related to the Jurassic of Europe, but appears to have developed earlier in Australia.

The Bundamba series comprises a thick series of massive sandstones, practically unfossiliferous. The beds attain a thickness of from 3000 to 5000 feet, overlying the Ipswich series and underlying the Walloon series. They are probably of middle Triassic age, and the equivalents of the Hawkesbury sandstone.

Jurassic System.—Rocks referable to this period belong to what was probably the greatest lake epoch through which the Australasian continent has passed. The principal lake extended from some point south of Dubbo at least as far north as the far extremity of the Bunya Bunya ranges of Queensland, north-west of Dalby—and probably still farther, up to the Cloncurry area; westwards it stretched more or less continuously to Lake Eyre, and still farther westwards to Lake Phillipson. The lake would thus have had a total length of 1200 miles from east to west, with a width from north to south of 700 to 800 miles. The strata deposited in this lake (or chain of lakes) are the main source of supply of artesian water in the great artesian basin. They vary in thickness from 300-400 up to over 4000 feet. Eastwards the basin extends through a narrow neck near Brisbane to the coast at the mouth of the Brisbane River, and also by a wider passage along the basin of the Clarence River between Ballina and Woolgoolga. That there is no outlet of consequence, if any at all, for the artesian basin in this direction is proved by the fact that a bore has been put down to a depth of 4000 feet at Grafton, and only a feeble trickle of artesian water has been tapped. The same remark applies to the bore on the race-course at Brisbane. The section shows somewhat arbitrarily the line of junction between Jurassic and Cretaceous rocks, and is to be regarded as provisional only; as most of the boring is done by percussion, the fossils in the strata passed through are usually in such a fragmental state that identification is often very difficult.

The section given below shows the hydraulic grade descending from Charleville as a centre N. to the Gulf of Carpentaria, and S.W. to Lake Eyre. At its south-western end the basin is apparently blocked by impervious pre-Cambrian or older Palaeozoic rocks, so that apparently it has no outlet in that direction. Towards the north a sill of older rock rises so high above the general floor of the basin that it would seem to go far towards checking any important underflow and outflow to the sea in this direction also. The explanation of the fall of the



Section across Great Artesian Basin from the Gulf of Carpentaria to the Great Australian Bight.

hydraulic grade seawards from Charleville, in Queensland, would seem to be either (*a*) that there are narrow subterranean outlets, not yet tapped in the bores, both in the direction of the Bight and in that of the Gulf of Carpentaria; or (*b*) that before the bores were sunk the chief outlet for artesian water was through those natural artesian wells, the mound springs. These are very numerous on the lower Flinders River in the north, and near Lake Eyre towards the south-western end of the basin. That springs connected with faults may supply part of the artesian water is obvious; but it is probable that by far the larger proportion has a meteoric origin, being derived from rain falling directly on the outcrop of the porous beds, or leaking into them from the channels of rivers. This supposition receives some confirmation from the Cainozoic analogue of the artesian basin at Perth where the interdependence between rainfall and the outflow of artesian water has been distinctly proved; but conditions in the Perth artesian basin are not in every respect analogous to those in the central Jurassic basin. For example, in the latter the factor of gas pressure is very important in helping to force the artesian supply to the surface. Over 90 per cent of the gas concerned in producing this pressure is nitrogen; gases like CH_4, CO_2, H_2S, etc., are present in far smaller proportions. This nitrogen is almost certainly not of plutonic origin, but is probably derived from the atmospheric nitrogen dissolved in meteoric waters supplying the artesian basin. The temperature of the water is in some cases as high as 204° Fahr., even when the water arrives at the surface. But, so far, the waters from the chief bores which evolve nitrogen have much lower temperatures than the above (see ARTESIAN WATER).

Strata of Jurassic age are also found on the eastern periphery of Australia and in Tasmania as well as in the coastal regions of Western Australia. In Queensland they are represented by the Walloon series. These beds cover a large area, and form the principal intake beds bordering the eastern margin of the great artesian basin. In places they are estimated to be about 4000 feet in thickness. They are the equivalents of the Talbragar series in New South Wales. The Walloon series have yielded an abundant fossil flora, the most characteristic types being *Equisetites rotiferum, Cladophlebis australis, Thinnfeldia* (3 species), *Sagenopteris rhoifolia, Taeniopteris spatulata* (*T. daintreei*), *Ptilophyllum pecten, Otozamites queenslandi, Araucarites polycarpa,* and *Brachyphyllum crassum.*

The coals of the Walloon series are rich in volatile hydrocarbons, and are more suitable for gas-making than for steam-raising purposes. The basal beds are calcareous, and at Roma yield natural gas. Over 80 per cent of the gas is methane, the remainder being partly petrol gas, partly inert gases. Mineral oil in small quantities has been obtained from six artesian bores between the Roma and Blackall districts. A small isolated patch of Jurassic rock also occurs at Talbragar, between Mudgee and Dubbo in New South Wales. These strata, which rest on an eroded surface of Hawkesbury sandstone, contain the following fossils:—*Taeniopteris daintreei, Alethopteris australis, Thinnfeldia falcata, Podozamites lanceolatus,* and *Baiera bidens.* Insects are represented by an ancestor of the true locust, the fossil form being described as *Cicada lowei.* Among the very numerous fish are *Leptolepis gregarius, Archaeomaene robustus, Coccolepis,* etc.

In Victoria there are three considerable areas of Jurassic rocks—in south Gippsland, the Cape Otway district, and the neighbourhood of Merino in the west. The strata consists of felspathic sandstones with abundant fresh fragmental felspar (perhaps of tuffaceous origin), besides shales, mudstones, and seams of coal. The seams are worked commercially in the Cape Paterson district and at the State-owned colliery at Wonthaggi. The coal is of fairly good quality, and the thickness of the seams varies from two to nine feet. The following are among the most characteristic fossils:—*Coniopteris hymenophylloides, Cladophlebis denticulata, Sphenopteris ampla, Thinnfeldia odontopteroides. T. maccoyi, Taeniopteris spatulata* and vars. *daintreei* and *carruthersi, Podozamites barklyi, Ginkgo robusta, Baiera subgracilis, Palissya australis, Brachyphyllum gippslandicum, Unio stirlingi.* At Cape Paterson a tooth of *Ceratodus* (*C. avus*) has been found, and scales of *Ceratodus* have been described from the parish of Kirrak in south Gippsland. Another interesting discovery has been that of a claw of a dinosaur, also in the Cape Paterson beds.

In South Australia, S. of Lake Eyre, there is a small Jurassic (possibly Triassic) coal-basin, preserved in a deep trough-fault. This is the Leigh's Creek coal-basin, whose strata of sandstone and carbonaceous shales are over 2000 feet in thickness, and comprise several seams of coal, one 47 feet in thickness. The coal is a hydrous brown coal. The chief fossils are *Thinnfeldia odontopteroides, T. media, Macrotaeniopteris wianamattae, Podozamites lanceolatus,* and an immense number of the fossil pelecypod *Unio eyrensis,* which occurred in almost every foot of the bore-core, from the surface to a depth of over 1500 feet.

The only marine equivalents of strata of Jurassic age within the Commonwealth are found on the west of Western Australia; they are chiefly developed in the Northampton district, extending thence by way of the Greenough River to Gingin, about 40 miles N. of Perth. The strata consist of white sandstones, ferruginous sandstones, light-coloured claystones, grits, limestones, and shales, with lignites. Their maximum thickness is quite 3000 feet. Occasional green patches in the ferruginous sandstone contain the phosphatic mineral dufrenite. Artesian water has been struck in this formation at Dongara and at Yardarino; but, after flowing for a few years, the flow has ceased—at the former locality through the bore becoming choked, and at the latter through failure of the supply. The following are the most typical fossils in this area:—*Otozamites feistmantcli, Zigno, Pagiophyllum* (?), *Pentacrinus australis, Trigonia moorei, Teredo* (found in its own bores in fossil wood), several varieties of Jurassic ammonites, and remains of large enaliosaurians.

A very important unit in the geology of Tasmania are the huge sills of diabase (granophyric dolerite and enstatite-augite-dolerite) often over 500 feet thick, which have been intruded into these coal-measures. They are almost certainly pre-Cainozoic. If they are of the same age as the great dolerite sills of the Karroo system of South Africa, and as the Antarctic dolerites that intrude the beacon sandstone formation of the Ross Sea region, they should probably be placed at the top of the Jurassic, and perhaps be connected with the breaking up of Gondwana Land at the close of Jurassic time.

They may, on the other hand, be of the early Cretaceous age, and connected with the diastrophism which was responsible for the great oceanic transgressions during Cretaceous times.

Cretaceous System.—This system is divided at present into the Rolling Downs formation below, and the Winton series (Cretaceo-Tertiary) above. The lower formation is almost wholly marine, except in the case of the Burrum coal-field of Queensland, with the adjacent Frazer Island (Great Sandy Island) and intermediate islands, which consist partly of freshwater beds. The Winton series is mostly of freshwater origin; but in places, as at Croydon, it contains in abundance *Rhynchonella croydonensis*, and at Fanny Bay and adjacent areas near Darwin is represented by a radiolarian shale, and by cherts containing casts of small *Belemnites*. The Winton beds vary from about 150 feet up to a maximum of 500 feet in thickness, while the Rolling Downs beds are in places about 2000 feet thick, perhaps more. The exact thickness is not always easy to determine, on account of a nearly conformable downward passage from Rolling Downs beds into Jurassic strata. The vast extent (about one-third) of the whole area of Australia, formerly covered by Cretaceous rocks shows that an enormous transgression of the ocean took place at this time, so as to develop a distinct epicontinental sea over the whole of east-central Australia. Cretaceous rocks are also developed on the NW. side of the Victoria Desert in Western Australia, as well as under the Tertiary limestones of the Nullarbor Plains fronting the Great Australian Bight, as proved in the Madura artesian bore. They are also represented at Perth by a narrow strip some thousand feet below sea-level, as is shown by the Clermont bore and the outcrop of white Cretaceous limestones and glauconites with phosphatic nodules at Gingin (60 miles N. of Perth) as well as by a similar strip extending along the coast from north of Geraldton towards North-west Cape.

The Cretaceous rocks of Gingin are specially rich in ammonites (six of which have affinities with *Haploceras daintreei*), *Inoceramus*, foraminifera and ostracods. The sponge *Peronella*, the coral *Coelosmilia*, and the brachiopods *Trigonesmus*, *Magas*, *Magasella*, etc., connect this Cretaceous fauna with that of the northern hemisphere. The marine fauna from this west-coast belt of Western Australia is closely allied to the Pondicherry Cretaceous fauna of India, and to that of South Africa; whereas that of the great artesian basin represents a peculiar type locally developed within this Australian Mediterranean. Lithologically the Winton rocks (formerly called desert sandstone) consist mostly of coarse sandstone that in the arid regions passes into quartzite, as well as of very siliceous white shales graduating superficially into porcellanite, and in places containing valuable deposits of precious opal. The latter are associated with remarkable large forms—known to the miners as 'pineapples'—of common opal pseudomorphous after glauberite, together with concretions—locally known as 'buns'—of barytes. Near Port Mackay in Queensland trachytic tuffs are said to be associated with the lower beds of the desert sandstone. This is the only record of contemporaneous volcanic activity in the whole Cretaceous system in Australia. Small seams of coal (too thin to be workable) and numerous silicified trees occur in places in this formation. The Rolling Downs strata are mostly friable sandstones rich in foraminifera, and rendered green by glauconite. In addition, on the Burrum coal-field and at Maryborough and Frazer Island sandstones and shales, with fossil plants and seams of productive coal, are now considered to be of Cretaceous age. The whole series is approximately 3000 feet thick. The Burrum coal-seams, of which about four are of workable thickness—that is, from three to four feet thick—contain coal of brittle, bright, black, bituminous character, remarkably free from ash, but too friable for export. The fossil plants recorded from this field show that forms like *Trichomanites laxum*, *Thinnfeldia media*, and *Taeniopteris daintreei* survived from Jurassic time. *Corbula burrumensis* and *Rocellaria terrae-reginae* are associated with the Burrum coal-measures. This recent discovery that part of the Australian Jurassic fauna and flora survived into Cretaceous time is obviously of considerable importance. The Styx River coal-field, 70 miles NW. of Rockhampton, contains several good productive seams up to five feet in thickness, and is considered to be of upper Cretaceous age and a little newer than the Burrum coal-measures. As regards the fossil fauna in the Rolling Downs beds, well-preserved remains of infusoria belonging to the Tintinnoidae, associated with diatoms and radiolaria, have been found in fine-grained limestones at Mitchell on the Maranoa River. The following is a list of specially characteristic fossils:—*Purisiphonia clarkei*, *Pseudavicula australis*, *Maccoyella barklyi*, *Nucula quadrata*, *Cytherea clarkei*, *Belemnites australis*, *Crioceras australe*, *Lamna daviesii*, *Aspidorhynchus* sp., *Belonostomus sweeti*, *Notochelone costata*, *Ichthyosaurus australis*, *Plesiosaurus macrospondylus*, *Cimoliosaurus*, *Aeschna flindersensis* (possibly an *Aeschnidium*), and many foraminifera, the Lituolidae being strongly represented.

The general evidence points to a progressive submergence of the Australian continent in Cretaceous time, leading to an encroachment of the sea southwards from the Gulf of Carpentaria across to the Bight. It is just possible that there may have been a narrow neck of land joining eastern to western Australia south of Lake Eyre. At all events, when the submergence was at its maximum, the isolation of eastern Australia from western Australia must have been nearly complete. The wide spread of the comparatively thin beds of the desert sandstone, mostly of freshwater origin, indicate that in upper Cretaceous time the Cretaceous seas were retiring from the continental area, and lacustrine conditions were taking their place everywhere—except locally, as at Croydon and Darwin. It may be added that Melville Island and Bathurst Island, N. of Darwin, are formed of Cretaceous rocks—apparently of Rolling Downs type; but little is as yet known of their fossil contents. The fact that lower Cretaceous fossils, especially small specimens of *Aucella*, *Scaphites*, *Histrichoceras*, etc., are being constantly washed up on the beach at the Point Charles lighthouse near Darwin shows that lower Cretaceous rocks underlie the strait which separates Melville Island from the mainland. It may be suggested here, very tentatively, that the vast transgression of the Cretaceous sea was perhaps causally connected with two other important geological events; the sinking in of Gondwana Land, leading to compensating uplifts of the sea-floor, and the wholesale injection of vast dolerite sills, which probably further contributed towards shoaling the ocean basins.

At the base of the Winton series (these

lowest strata being perhaps of the upper Cretaceous age) smoothed boulders, one at least striated by ice, are found in situ in a fine-grained shaly sandstone. Some are five feet in diameter. They are evidence of floating ice in late Cretaceous time. Small unproductive coal-seams occur in the series, conformably overlying the Rolling Downs formation, with a maximum thickness of 2000 feet. The Winton series which covers such a vast area of the great artesian basin is probably Cretaceo-Tertiary in age.

Cainozoic Era.—The classification and correlation of the rocks of the Commonwealth belonging to this era present many difficulties. It is harder in Australia than in northern Europe to separate the post-Tertiary from the Tertiary rocks. In northern Europe glacial deposits (chiefly of Pleistocene time) are widespread, but in Australia such glacial evidence is wholly restricted to an area of less than 500 square miles centring on Mount Kosciusko. Only in Tasmania can evidences of Pleistocene ice action be traced over a large area. Then, in regard to the correlation of the Australian Tertiaries with those of Europe, the statement of an Australian palaeontologist still applies:—'Many attempts have been made to fit the Tertiaries of southern Australia into the British Procrustean subdivisions, and I do not know that the results are any more satisfactory to the strata than they were to the guests of Procrustes himself.'

Direct comparison of Australian Tertiary forms with those of Europe may prove fallacious, unless supplemented by other evidence, for there is no direct proof of the existence of any highway for migration of marine organisms from the seas of the southern hemisphere into the *Tethys* area in early Tertiary time.

Tested by the Lyellian method—the determination of the percentage of recent mollusca in the series—the Tertiary marine faunas of Australia can be compared with the recent fauna of Australian seas; but it is now clear that some Australian palaeontologists who worked on these lines did not recognize that in many of our older Tertiary deposits the marine molluscan fauna is not, as was originally supposed, littoral in habit, but belongs to a moderate depth; and recent dredging operations have demonstrated the fact that many forms in the older Australian Tertiaries, formerly thought to belong to extinct species, are now living at some depths off the Australian coasts. If one relies for correlation on the evidence of wide-ranging and rapid-moving types, like sharks and whales, it may be noted that *Carcharodon angustidens* and *C. megalodon*, of the older Australian Tertiaries, are characteristically Miocene in the northern hemisphere. Then, too, the toothless whales of the Victorian older Tertiaries belong to a group which in the northern hemisphere appears to be chiefly Pliocene. On the whole the tendency of late has been to refer the so-called Eocene strata of southern Australia to some part of Miocene time. Recently it has been proposed to divide the Tertiary rocks of Victoria into four systems, based largely upon the correlation of various species of *Lepidocyclina*. The classification is as follows:—Werrikooian (upper Pliocene); Kalimnan (lower Pliocene); Janjukian (Miocene); and Balcombian (Oligocene).

The Balcombian series consists chiefly of sands and shelly marls. These contain an abundant marine fauna in which are represented fishes, polyzoa, echinoderms, gorgonids, corals, sponges and foraminifers. Intercalated with the marine series are freshwater deposits containing beds of brown coal of good quality and extraordinary thickness; a bore sunk at Morwell to a depth of 1000 feet passed through 888 feet of brown coal. These beds are probably of Miocene age, lying above the older basalt at the top of the Oligocene Balcombian formation and below the Janjukian limestones.

The Janjukian series, which is of Miocene age, consists largely of polyzoan (*Cellepora gambierensis* being specially characteristic) and *Lepidocyclina* limestones, and the same association has been noted in the deposits of South Australia. The Table Cape series of Tasmania has a well-developed *Turritella* horizon, in which the remains of a fossil whale have been found, as well as a very old type of marsupial (*Wynyardia bassiana*). Many of the Tertiary leaf-beds preserved in the deep leads of New South Wales (Dalton and Gunning) and Victoria (Bacchus Marsh, Narracan, Berwick, Pitfield, Cobungra, Dargo and Bobong) have been referred to the Janjukian series. The Nullarbor Plains, some 400 miles long and extending 300 miles inland from the cliffs facing the Australian Bight, are formed of a tough Janjukian limestone, rich in gastropods and polyzoa above, passing downwards into soft clayey sands containing subartesian water, in granite sands underlying lignitic estuarine silts and clays.

The Kalimnan series, regarded as of lower Pliocene age, are often largely formed of glauconite sands; these beds are well-developed at Beaumaris, where they consist of sandy marls in which occur numerous shells and the teeth of sharks. The fauna is chiefly molluscan, and is represented by such types as *Ancilla papillata*, *Voluta fulgetroides*, *Fusus gippslandicus* and *Trigonia margaritacea*. The plant-remains of the deep leads at Haddon in Victoria are referred to this period.

The Werrikooian series of upper Pliocene age comprises both freshwater and marine beds. The former is represented by the Dunolly gold drift, in which we have marsupial remains represented by *Phascolomys pliocenus*. The latter possesses a rich molluscan fauna, which includes a large percentage of living species. The remains of huge struthious birds (*Genyornis* and *Dromornis*) have been found in the Pliocene of Queensland, New South Wales and South Australia. This bird was as large as the moa of New Zealand.

Meanwhile the sequence of events in Cainozoic time along southern Australia and Tasmania, from the close of Cretaceous time, may be briefly stated as follows:—

Oligocene.—In the Port Phillip area in Oligocene time, the deposition of the Balcombian fluvio-marine series, at least 400 feet in thickness. This was followed by the outpouring of the older basalts and andesites, burying leaf-bearing, fluviatile and lacustrine deposits (the 'deep leads') under a thickness of 100 to 1300 feet of lavas and tuffs, developed chiefly in Victoria, New South Wales, and south-eastern Queensland. Tasmania was united to Australia at this time, and occupied by a primitive marsupial fauna neither distinctly polyprotodont nor distinctly diprotodont. *Wynyardia bassiana*, of the Tasmanian Miocene, was descended from this.

Miocene (Janjukian).—Development of marine, estuarine and lacustrine silts and clays, with beds of lignite, at Moorlands near Murray Bridge; near Adelaide; at Lal Lal and Morwell in Victoria (the lignites at the latter are 888 feet thick and full of *Callitris cupressiformis*,

the silver-barked mountain oak). The lignite deposits of Riverina belong to this series. The Moorlands lignites contain exquisitely preserved skeleton leaves of waratah and banksia. A deep and prolonged subsidence followed, affecting the whole southern coast of Australia and at least the northern part of Tasmania, the pre-Miocene Bassian land-bridge breaking down. North of the Australian Bight the middle Miocene sea crept inland for from 200 to 300 miles, soft marly strata with cherts and flints being followed by at least 200 feet of hard gasteropodan and polyzoal limestone, which now forms the surface of the Nullarbor Plains for a distance of at least 400 miles from east to west. At Norseman on Lake Cowan, at Cape Riche, and near Albany and up to the southern base of the Stirling ranges, the Janjukian strata are represented by deposits essentially of sponge-spicules (spongilite beds). East of the Nullarbor Plains the lands bordering Spencer and St. Vincent gulfs are partly formed (as at Point Turton and Aldinga) of beautifully preserved polyzoa and gastropods. The sea encroached far up the Murray to beyond Wentworth in New South Wales, while much of Victoria from Port Phillip to Gippsland was also submerged. In the river-eroded cliffs of the lower Murray *Cellepora gambierensis* forms sub-spherical masses, each of the size of a man's head. At Table Cape in Tasmania the Janjukian beds are about 80 feet thick, rich at their base in *Crassatellites*. In South Australia the polyzoal limestone is widely used as a building-stone, being soft enough in the quarries to be sawn with cross-cut saws, but hardening when weathered.

Older Pliocene (Kalimnan).—The southern shores of Australia began to rise. Shell-banks, specially characterized by *Ostrea sturteana*, were formed, associated with marls of shallow-water origin; but in places a considerable amount of glauconite was formed, pointing to local deep-water (100 fathoms or so) conditions. Among the whales *Scaldicetus macgeei* was characteristic. Some of the newer 'deep leads' (such as those of Gulgong in New South Wales, with *Plesiocapparis, Penteune clarkei, Meiolania*, etc., and the lacustrine beds of Launceston with *Spondylostrobus smythii, Plesiocapparis, Penteune allporti*, etc.) may perhaps be referred to this time. In Papua the Port Moresby beds, largely in the form of radiolarian cherts weathering in immense spheroids, are perhaps to be referred to some part of the older Pliocene. The immense belt of alkaline lavas and tuffs which extends from Casterton in Victoria through Mount Macedon, the Gib, Barigan (near Mudgee), the Warrumbungle and Nandewar ranges in New South Wales, and the Macpherson Range and the Glasshouse Mountains to Clermont, Springsure and Yeppoon near Rockhampton in Queensland—together with the Port Cygnet alkaline series, the nepheline-basanite of Table Cape, the melilite basalt of Sandy Bay near Hobart, the nepheline-melilite-basalt and nepheline-eudialyte-basalt of Shannon Tier in Tasmania—were erupted about this time.

Newer Pliocene (Werrikooian).—Further tectonic movements of the earth's crust caused elevations in some places, depressions in others. Spencer and St. Vincent gulfs were forming as the result of trough-faulting, much marine Pliocene material being deposited in St. Vincent Gulf, near the Croydon bore at Adelaide, and at Limestone Creek in the Glenelg River district of Victoria. Vast sheets of basalts, proceeding from dyke eruptions, then flooded the nearly even surfaces of the eastern and south-eastern Australian and Tasmanian peneplains. In South Australia they are represented at Kangaroo Island; in Western Australia at Bunbury, on the lower Blackwood River, and at Black Point on the coast. The fact that the flora of this period shows scarcely any trace of differentiation suggests that the land had a low relief. These extensive basaltic outflows appear to date near the close of Pliocene time.

Pleistocene (Kosciusko epoch).—In either very late Pliocene or early Pleistocene time the earth's crust, in the Australian and New Guinea region, was subjected to further considerable diastrophism. The eastern periphery of Australia (including Tasmania and the Mount Lofty and Flinders ranges of South Australia) was warped up to altitudes of 2000-3000 feet above the sea. The movement, being differential, carried an area such as Kosciusko to a height of 7000 feet above sea-level. Great subsidence and fracturing took place along the eastern coast of Australia, especially along the area of the Great Barrier Reef. In New Guinea the Cretaceous-Pliocene strata underwent intense orogenic movements, mountains being produced up to and over 15,000 feet in height. A glacial age supervened, which had many phases. Kosciusko was capped by an ice calotte from its summit to about 5000 feet above sea-level. In Tasmania the glaciation was naturally very heavy on the west coast and western highlands, the modern heavy rainfall, which comes from the west, being at that time largely replaced by snowfall. Not only were the Western Tiers of Tasmania and the highlands of the western coast covered with firn-fields and glacier ice, but at the township of Gormanston glacial boulder-clays were formed only a few hundred feet above sea-level, and on the western side of the Cray-croft Range moraine material descends to within 250 feet of sea-level. This glaciation affected (probably synchronously) New Guinea, and it was probably during a phase of this glacial age that the rhododendron migrated from Papua to the Bellenden Ker Range in Queensland (over 5000 feet high), where it has since become isolated through the amelioration of the climate. The phenomena of maximum glaciation seem to call for a lowering of temperature of approximately 9° Fahr., as compared with that of the present day.

Partly if not wholly synchronous with this ice age (or possibly with one of its interglacial phases, if there were any such), was an epoch when the central plains of Australia had a good rainfall, and the present area of internal drainage was only beginning to come into existence. Great herds of herbivores, of much larger size than their nearest modern allies, roamed over what are now the arid regions of the lower steppes near Lakes Eyre, Frome, and Callabonna. This fauna comprised *Ceratodus, Megalania prisca, Meiolania, Palimnarchus pollens, Diprotodon, Nototherium, Macropus*, and *Sceparnodon*, with the powerful carnivorous *Thylacoleo*, and the carnivorous *Thylacinus, Sarcophilus*, and *Canis dingo*. During this Kosciusko epoch New Guinea was still united to Australia, and the recent discovery of *Nototheria* (*N. tasmanicum* and *N. mitchelli*) at Mowbray Swamp in the north-western part of Tasmania, taken in conjunction with other evidence, suggests that Tasmania was once more united to Australia by way of the Bassian bridge. Gigantic ancestors of the emu, *Genyornis* and *Dromornis*, were

associated with this fauna; the birds were probably about 13 feet in height. A fine collection of this fauna is in the Adelaide Museum.

Along with the uplift there was, no doubt, a beginning of complementary subsidences, which became much more pronounced after the uplift ceased. The rift valleys of Torres Straits, Port Curtis, Cairns, Cooma, Bass Strait, Hobart, Port Phillip, St. Vincent and Spencer gulfs, Lake Torrens, and the west coast of Western Australia, gradually developed, together with those many faults traversing the highlands of the warped peneplains of Australia and Tasmania, whose unreduced scarps attest their comparatively recent origin. The recent volcanic craters of Mount Gambier, Tower Hill, etc., may be referred to this epoch. Possibly negritoid man entered Tasmania by way of the Pleistocene Bassian bridge before its final collapse. From the Kosciusko epoch to the present day canyon-cutting has been proceeding in the elevated peripheral portions of Australia and Tasmania, this process tending to push the divides farther inland.

Among recent formations may be mentioned the dune rock, partly cemented by lime, of Fremantle and the SW. coast of Western Australia, of Cape Northumberland near the border of South Australia and Victoria, and of Warrnambool, Sorrento, etc. At Sorrento this rock is about 1000 feet in thickness, and at least as thick near Perth. The heavy silting along the Victorian coast which has produced the Gippsland lakes, as well as the silting off the Maryborough coast, where the dunes are 800 feet high, and that between Shark Bay and North-west Cape in Western Australia, are all connected with the cusps of slack water formed next the shore, where great ocean currents meet. Mention may also be made here of the sand dunes of the lower steppes of Australia, and of the Victoria Desert. The latter are only superficially formed of loose sand to a depth of a foot or so; then the formation passes into a tough calcareous rock. In the Lake Eyre region, again, only the surface of the dunes is loose sand; inside they are formed of a certain amount of loamy material, especially near the old deltas of Cooper's Creek and of the Diamantina River. In most parts of central Australia these dunes derive their sand from the breaking up of the soft Jurassic and Permo-Carboniferous sandstones, as well as the Winton (desert) sandstones. The moving dunes of central Australia are of a bright brick-red colour.

In addition to the alluvial plains and rivers, mention may be made of the laterites (pindan gravels) of Western Australia, the nodular tuffaceous limestones (kunkar) of South Australia, the saline deposits of the inland plains, and the coastal salinas. It is clear that subsidence has been recently in progress at the southern end of Tasmania, and the large 'bank' recently discovered 200 miles farther south is obviously an immense sunken segment of a once greater Australia. Submergence has also taken place for a great distance along the eastern coast of Australia. As already stated, this is partly due to the recent melting of ice and snow in Antarctica, bringing about a universal rise of sea-level; but it cannot be entirely due to this, as the recent submergence is in places of the order of fully 200 feet, and it is doubtful whether the ice of Antarctica, from the great ice-age down to the present time, can have affected sea-level to the extent of more than about 100 feet.

The so-called 'raised beach' of about 15 feet is so general round Australia that it is probably due to a recent sinking of the sea-level. The 50-ft. raised beach near Darwin is probably connected with recent orogenic movements in New Guinea. These recent movements have caused a local emergence of the coral-reefs in south-eastern Papua of 1000 up to 2000 feet. The Great Barrier Reef of Queensland, some 1200 miles in length, represents in its uppermost portion a marvellous area of growing reef, the bulk formed of coral.

Earthquake shocks, most frequent in the area between the gulfs of South Australia, Bass Strait, and Kosciusko, show that coastal readjustment is still in slow progress in those regions. In New Guinea sharp shocks proceed from the active volcanic zone near Mount Victory. Many earthquake shocks which reach the eastern side of Australia emanate from the deep trench E. of the Tongan and Kermadec islands. Western Australia is practically free from earthquakes.

Prehistoric Man.—As is well known, the aboriginal inhabitants (now unfortunately extinct) of Tasmania belonged to the negrito race and were in a palaeolithic state of civilization. They had no knowledge of producing a cutting-edge on stone by grinding it down on a hone-stone; all their instruments were of the rudest possible type, and roughly chipped. Neither could they build canoes of the sea-going type, being satisfied to construct them from the bark of trees stripped off in long sheets, sewn up at the ends, and plugged with clay. In such frail craft they navigated their own rivers and lakes. In Tasmania no trace of aboriginal man has been found that considerably antedates the coming of the white man. On the mainland of Australia the aboriginal, as far back as we have any traces of him, had attained to a neolithic stage of civilization. The following appear to be the only evidences of the existence of man in Australia that approach high geological antiquity:—(1) The Tasmanian aborigines probably crossed Bass Strait (as they were ignorant of the art of making sea-going canoes) by an almost (if not quite) continuous land-bridge. (2) On the mainland of Australia there is possible evidence in some of the old cemented sand dunes near Warrnambool of impressions attributable to human bodies and feet. Many people, however, have doubted the genuineness of these imprints. In New South Wales several stone tomahawks were dug up a few years ago in the cutting of a canal at Shea's Creek, between Botany Bay and Redfern; these tomahawks were embedded in peat many feet thick, underlying marine estuarine beds at a total depth of 15 feet below high water. It may be concluded that the whole of our coast-line has subsided by 15 feet; or else, as the result of the melting of ice and snow in the Antarctic regions, sea-level has risen by that amount since the time when the aborigines lost their tomahawks in this swamp. In either case a considerable lapse of time, perhaps of the order of several thousands of years, would be needed to account for this change in the relative level of land and sea. (3) It has often been stated that stone tomahawks have been discovered in the deep leads of Victoria. The following, as far as is known, is the only case in which the tomahawk may possibly be considered as contemporaneous with the deep lead. Near Maryborough in 1855 a basalt axe-head was found four feet below the surface in one of the tributaries of the main Bet Bet

lead. The main lead is covered by basalt, believed to be of Pleistocene age; but the tributary lead, in which the axe-head was found, is not covered by basalt, so that the finding of an axe-head at a depth of only four feet does not necessarily imply any great antiquity for it. (4) If *Canis dingo*, as seems almost certain, was brought to Australia in canoes by early aboriginal man, man and the dingo—the latter a northern hemisphere type of wolf—arrived in Australia synchronously. Remains of dingoes in a cave at Mount Macedon show that it was contemporaneous with extinct marsupials. Therefore man, too, was probably contemporaneous with them in Australia and Tasmania. See ABORIGINES, ARTESIAN WATER, ANTARCTICA.

Geraldton Wax Flower. See CHAMAELAUCIUM.

Geraniaceae, a large family of herbs or shrubs found chiefly in northern temperate latitudes, but very abundant in South Africa; a few species are found in South America. Four genera with nine species are indigenous to Australia. The genus *Erodium*, abundant in Europe and North America, is represented by one endemic species (*E. cygnorum*), a biennial herb with deeply incised leaves and clusters of small blue flowers, popularly known as 'crowfoot' or 'stork's bill.' (See FODDER-PLANTS.) It extends across the continent. The genus *Pelargonium* is largely South African. There are 3 indigenous species. *P. australe*, a perennial herb with a stout rootstock, has two forms, one (with showy flowers) growing on the sandy sea-coasts, the other inland. The coastal form is more robust and larger in all its parts than the other, and its taproot descends to a great depth; it is of some value as a sand-binder. See GERANIUM.

Geranium, a widespread genus of the family Geraniaceae, consisting of herbs (rarely undershrubs) found chiefly in northern temperate regions. Four species are indigenous to Australia. *G. pilosum*, popularly known as 'crowfoot' (as are other members of the family) is found in all the States. It is known in Tasmania as 'native carrot,' and is highly prized as a fodder-plant. The barb-pointed fruits, however, cause irritation to sheep, and occasionally blind them, besides depreciating the value of the fleece.

Geum, a genus of the family Rosaceae, consisting of perennial herbs with yellow, white, or red flowers. The calyx-tube is short and open, 5-lobed; petals 5, broad, spreading; fruit a head of dry carpels surrounded by the persistent calyx, each carpel terminating in a thread-like awn. *G. urbanum*, found in eastern Australia, is the Avens or Herb Bennet of Britain. Its root, called by the old herbalists 'clover root,' has an aromatic clove-like odour; it possesses astringent properties, and has been used in cases of diarrhoea, etc.

Ghost Sharks (Holocephali) are distinguished from the true sharks by numerous structural details, the most obvious of which is the presence of but one gill-opening on each side as in the higher fishes; the mouth, too, is provided with bony grinders instead of teeth. The skin is quite smooth in most species, and there is a stout spine before the dorsal fin. The tail is usually prolonged into a long filament, and the male is provided with a peculiar bony hook on the forehead. Ghost sharks produce large eggs enclosed in horny cases of various forms. *Chimaera ogilbyi* is occasionally taken by trawlers on the New South Wales coast in depths of about 60 fathoms; when first caught it is a glistening silver in colour. Several other species are known from Australian waters. Elephant fishes (q.v.) belong to the same order.

A.R.McC.

Giant Cod. See ROCK COD.

Giant Lily. See AMARYLLIDACEAE.

Giant Maidenhair. See BURRAWANG and FERNS.

Giant Nettle. See LAPORTEA.

Giant Perch (*Lates calcarifer*), a widely distributed species, ranging from India and China through the Indo-Australian archipelago to northern Australia. Though essentially an estuarine fish, it commonly ascends rivers into fresh water, and often establishes itself in lagoons that can be reached only in times of flood. It is prized both as a food and as a game fish, attaining a length of nearly six feet, and weighing over 50 pounds. In parts of Queensland it is known as 'palmer,' and shares the native name of 'barramundi' with several other large freshwater fishes.

A. R. McC.

Gibber, an aboriginal word which signifies either a small stone or rock-ledge (the 'g' is hard). In the former sense it is usually applied to the small, polished, purple-brown stones, packed closely together, which cover a large part of the far-stretching plains of central Australia —known for that reason as 'gibber-plains' or 'gibbers.' These stones are formed by the gradual weathering of the quartzite caps of the flat-topped hills so common in that area. As the softer rock beneath is broken up, the stones fall close together, and are polished by the constant wearing action of wind-blown sand—especially during the dry season, when they are fully exposed to the elements. After rain they are partly protected by a rich growth of grass. When connoting a rock-ledge, the term is associated chiefly with the shelters ('gibber-gunyahs') which served many aboriginal tribes as homes and burial-places, notably in the Hawkesbury-sandstone district of New South Wales. These occur as recesses in the sandstone escarpments, each overhanging 'gibber' being a more or less tabular mass of rock often several feet thick. See CHATS and GEOLOGY.

Giblin, WILLIAM ROBERT (1840-1887), born at Hobart on 4 November 1840, and educated at the High School there, was called to the local bar in 1864, and entered politics as member of the assembly for Hobart in 1867. He was a member of the Wilson (1870-2) and Kennerley (1873-6) ministries; in 1877 he joined Philip Fysh (q.v.) as treasurer, taking the premiership next year, but for nine months only. Late in 1879, however, he formed a coalition ministry which lasted (mainly by absorbing successive leaders of the opposition) until 1884. He then left politics, took a puisne judgeship in 1885, and acted as chief justice from March to November 1886; in October-November of that year he administered the government after the departure of Sir George Strahan, being the first native-born Tasmanian to do so. He died on 17 January 1887. He represented his colony at international conferences in 1881 and 1883.

Gibney, MATTHEW (1838-1925), born in Ireland, was ordained priest on 14 June 1863, and in August of that year sent out to Western

Australia to work under Bishop Brady. In 1882 he was made vicar-general, and in 1886 coadjutor-bishop of Perth. Bishop Griver dying on 1 November in that year, Dr. Gibney was consecrated bishop of Perth in the cathedral of that city by Cardinal Moran on 23 January 1887. He retired from active work in 1910, and died at Perth on 22 June 1925. Outside his own State Dr. Gibney is probably most widely known from an incident that occurred during his visit in 1880 to the eastern colonies, to raise funds for the Western Australian orphanage. He happened to be near Glenrowan in Victoria when the gang of bushrangers under Ned Nelly (q.v.) seized that township and were attacked by a large force of police from Melbourne. His proposal to go straight to the hotel which the gang was holding, and do his best to induce them to surrender, was vetoed by the officer in command; but, when the hotel was seen to be on fire, he insisted on going into it to administer the last sacraments of the church to any bushrangers who might still be alive. Finding that all within the building were dead, he just managed to escape through the flames. The courage and piety thus displayed won him admiration throughout Australia. E.M.O'B.

Gidgee. See ACACIA.

Giffen, GEORGE, born in Adelaide on 27 March 1859, is the best all-round cricketer South Australia has produced. From 1876 to 1904 he played for South Australia regularly. His first appearance in test cricket was against Shaw's eleven of 1881-2, and he took part in test matches in 1882 (England), 1882-3 (Australia), 1884 (England), 1884-5 (Australia), 1886 (England), 1891-2 (Australia), 1893 (England), 1894-5 (Australia), and 1896 (England). In 1893 he headed the Australian bowling averages with 16 wickets for 21.37 runs, and in 1894-5 took 34 wickets for an average cost of 24.11, and was second in the batting averages with 52.88. His total score in test cricket was 1238 runs (average 23.35) and his bowling average 27.09 (103 wickets for 2791 runs). But outside test cricket some of his achievements were extraordinary. In the 1886 team he topped both the bowling and the batting averages; he made 18 centuries in first-class cricket; playing for his colony against Victoria in 1886, he took 17 wickets for 201; playing for South Australia against Lord Hawke's team of 1887-8, he took eight wickets (doing the 'hat trick') and scored only 118 in his two innings simply because he could get no one to stay with him; in 1891 he took 12 wickets for 192 in an intercolonial game, and in one innings made 237 runs; in a similar game in 1892 he took 16 wickets for 166, and in one innings made 271 runs. In 1884, playing in the Australian test team against the Rest of Australia, he took all the wickets in the second innings for 66 runs. Lord Hawke has called him 'dogged, skilled, shrewd . . . . the greatest Australian all-rounder.' In 1898 he published *With Bat and Ball,* a valuable series of sketches of Australian cricket and cricketers. Off the field he was employed in the public service (first of South Australia, after 1900 of the Commonwealth) in the postmaster-general's department, from which he retired with a pension on 27 March 1925. See CRICKET.

Gilbert, CHARLES WEB, born near Talbot in Victoria on 18 March 1867, was while still a boy apprenticed to a catering firm in Melbourne and set to mould figures in sugar-icing for wedding-cakes, etc. To improve his work the boy attended the art school attached to the Victorian national gallery, and soon determined to devote himself to sculpture. His first important work, 'The Vintage Offering,' was exhibited with the Yarra Sculptors' Society in 1897. For the next 16 years he worked steadily both on imaginative works and on a series of busts of notable Australians, including Alfred Deakin (bronze, in the library of the federal parliament), George Reid (marble, in the same library), Edward Holroyd (marble, in the library of the State law courts), and Bernard O'Dowd (bronze, in the Victorian national gallery). In 1914 he visited Europe, and for a time exhibited regularly at the Royal Academy; his head, 'The Critic,' exhibited in 1917, was purchased with funds of the Chantrey bequest for the Tate Gallery in London. In 1918 he was commissioned by the Commonwealth to execute models of battlefields in France in which Australian troops had been engaged, among them Pozières, Messines, Dernancourt and Mont St. Quentin. He has also designed the war memorials at Mont St. Quentin and Port Said, a colossal figure of an 'Anzac' for Broken Hill, many minor war memorials, and a statue of Matthew Flinders for Melbourne. His bronze 'Dreamer' is in the Melbourne gallery. W.M.

Gilbert. JOHN. See BUSHRANGING.

Giles, WILLIAM ERNEST POWELL (1836-1897, son of William Giles who was for 20 years general manager of the South Australian Company, was born at Bristol in England and educated at Christ's Hospital, and on leaving school in 1849 joined his family in South Australia. In 1852 he went digging on the Victorian goldfields; he then worked as a clerk in Melbourne, but, preferring an open-air life, obtained employment in reporting on new country west of the Darling (1864-5), and later joined an exploring party in Queensland. In 1872 he returned to his own colony and entered on the first of four important expeditions that opened up the country north-west of Lake Eyre and pierced the unknown desert lying between South and Western Australia. Details of these expeditions are given under EXPLORATION BY LAND; here it may be mentioned that the first (1872) traversed the area between Chambers' Pillar and Lake Amadeus, the second (1873-4) that between the Alberga River and the Tomkinson and Rawlinson ranges (these two were backed by Baron von Mueller and some wealthy Victorians), while for the third—which penetrated the desert westwards along the line of 30° S. lat.—and fourth—which went up the valley of the Murchison and along the line of 25° S. lat. to the central telegraph line at Peake Downs—Giles was supplied with camels and other necessaries by Sir T. Elder of South Australia. For these explorations Giles received the founder's medal of the Royal Geographical Society of London. His journeys of 1872-4 he described in a pamphlet published in Melbourne in 1875, and his transcontinental journeys in *Australia Twice Traversed,* published in London in 1889. He died at Coolgardie on 13 November 1897.

Gill, SAMUEL THOMAS (1820-1880), born in South Australia in or about 1820 and in his early years apparently a devotee of hurdle-racing, first came under public notice as a member of the ill-fated Horrocks exploring expedition of 1846, and had named after him the lake now known as Lake Dutton. In February

1847 his sketches of the country passed through were the principal attraction at an 'artists' exhibition' in Adelaide. In 1849 he published a dozen sketches of well-known colonists, his first venture in the line of polite caricature, and by this time seems to have been locally noted as a landscape painter. In 1851 he went to the Victorian goldfields, and in August 1852 published a series of 24 drawings made there; for the next three years he rapidly produced lithographs and water-colour drawings of Victorian scenery and notabilities; his work also reached London, the goldfields pictures being republished there in 1853 and a set of illustrations to Wilson's *Rambles at the Antipodes* in 1859. Between 1856 and 1862 he paid several visits to Sydney, occasionally staying at Hunter's Hill. But his headquarters were always in Melbourne, where he lived a spasmodic life of the kind considered 'artistic' in those days; no published work of his is known subsequent to 1865, and no water-colours later than 1874, but he was still living in 1880. On 27 October of that year he died suddenly on the steps of the general post-office. His principal works, besides those already mentioned, are *Diggers and Diggings of Victoria* (1855), a series of lithographs; *The Australian Sketchbook* (1855); *Scenery in and around Sydney* (1856), six lithographs; *Victoria Illustrated* (1857), views engraved on steel or copper; *Sketches in Victoria* (1860), 25 in number; a second series of *Victoria Illustrated* (1862); and a set of coloured lithographs illustrating bush life (1865). His work is valuable rather as reproducing the life and costume of his times than as art.

Gill, WILLIAM WYATT (1828-1896), born on 27 December 1828 at Bristol in England, and educated at Highbury College and the university of London (B.A., 1850), was in 1851 chosen by the London Missionary Society to take up missionary work in the Pacific islands. For 20 years he was stationed at Mangaia in the Cook group, but in 1872 established mission stations on the mainland of Papua, and in 1876—while on a visit to England—published *Life in the Southern Isles* and his best-known work, *Myths and Songs of the South Pacific*. Returning to the Cook group that same year, he worked on Raratonga until 1883, when his health gave way and he was forced to retire from active service and reside in Sydney. There for three years he revised his Raratongan translation of the Bible; he also published in London *Jottings from the Pacific* (1885) and—in conjunction with James Chalmers (q.v.)—*Work and Adventure in New Guinea* (1885; German translation issued at Leipzig in 1886). After a visit to London to see the Raratongan Bible through the press, he settled in Sydney, issued in 1892 a small pamphlet on *The South Pacific and New Guinea*, and died on 11 November 1896. For his literary work the university of St. Andrews made him LL.D.

Gill-birds. See WATTLE-BIRDS.

Gillies, DUNCAN (1834-1903), son of a Glasgow market-gardener, was born at Over-Newton in January 1834, educated at the Glasgow high school, and placed while still a boy in a local counting-house. In 1852 he migrated to Port Phillip and found his way to the Ballarat goldfield, where he became a leader among those disaffected to the government, but discouraged violence and refused to take any part in the Eureka Stockade affair. He was elected a member of the Ballarat mining court, and then of the board which in 1858 superseded that court, and in 1859 entered the Victorian assembly as miners' representative for Ballarat West. He was soon known as a good debater, but made no other mark until in 1867 he took a prominent part in opposing the grant to Sir Charles Darling (q.v.), and on 6 May 1868 took office in the short-lived Sladen ministry as president of the board of lands and works. His constituency at once rejected him, and in 1870 he was elected member for Maryborough, transferring himself to Rodney in 1877 and to the Eastern Suburbs (of Melbourne) in 1889. From 1872 onwards he was among the most prominent of the political leaders, administering the department of railways for the Francis (1872-4), Kerferd (1874-5), and two Service ministries (1880, 1883-6), and the department of lands for the McCulloch ministry of 1875-7; during the intervals—which were almost entirely occupied by Berry ministries (see BERRY, SIR GRAHAM)—he consolidated his position as a future party leader; and, when the second Service ministry, which was a coalition of the conservative (Service) and radical (Berry) parties, had to be reconstructed, Gillies replaced Service and became premier, with Alfred Deakin (q.v.) as his Berryite colleague. For the next four years he enjoyed a popularity and prosperity almost unexampled in Victorian politics. A swelling revenue enabled him to pursue a policy of expansion with regard to railways (of which he retained the administration), tramways, wharves and docks, while his colleague greatly extended the system of irrigation in northern Victoria; and by 1889 his accumulated surpluses amounted to over £1,600,000—more than a seventh of the year's income. But acute labour troubles, culminating in the maritime strike of 1890, destroyed the financial basis on which Gillies had erected an over-extravagant structure, and on 5 November 1890 his ministry fell. Relegated for a time to opposition, he was in 1894 made agent-general for the colony by J. B. Patterson, who had been his commissioner of customs in 1889-90; but he held the position for three years only, and on 14 October 1897 re-entered the assembly as member for Toorak, a seat which he retained till his death. On 14 October 1902 he was unanimously elected speaker. His health, however, was already precarious, and on 12 September 1903 he died of heart failure in the speaker's apartments.

Persistently interested in local politics—so that the agent-generalship was irksome to him—he was at the same time a strong supporter of federation, and represented his colony at several intercolonial conferences, at the federal convention of 1891, and on the federal council of 1885-9. In 1887 he refused a K.C.M.G.

Gipps, SIR GEORGE (1791-1847), born at Ringwold in Kent in 1791 and educated at the King's School, Canterbury, and the royal military academy, Woolwich, joined the royal engineers as second lieutenant in 1809 (1st lieutenant, 1809; 2nd captain, 1814; 1st captain, 1826; brevet-major, 1837; lieutenant-colonel, 1841). From 1811 he served in the Peninsular war, was wounded at the storming of Badajos, and for gallantry in this action was mentioned in despatches. In 1814 he joined the army in Flanders, and after Napoleon's escape from Elba was ordered to put Ostend into a condition of defence; he thus missed Waterloo. He remained with the army of occupation in France until July 1817; then, after a period of freedom spent in Euro-

pean travel, he returned to duty at Chatham, and in November 1824 was ordered to the West Indies, where he remained five years. His able reports on the subject of slave-emancipation brought him such credit that, on his return to England in 1829 to take command at Sheerness, he was appointed to two government commissions—one Irish, the other English—for the definition of electoral and municipal boundaries. In 1834 he became secretary to Lord Auckland, then first lord of the admiralty, and in 1835 was sent to Canada with Lord Gosford and Sir Charles Grey to investigate the colonists' alleged grievances. The sagacity and insight he displayed in this work won him the succession to Sir R. Bourke as governor of New South Wales, and he took up his duties at Sydney on 24 February 1838.

Gipps was an exceptionally able governor, but his administration was unpopular with all classes of the community, the difficulty of his position being increased by the fact that it was still the governor's duty to maintain the authority of the colonial office against the will of local political leaders. Both politically and economically the colony was in a state of transition during his administration. The demand for responsible government was already insistent, and could no longer be ignored. As a preliminary to the grant of a measure of responsibility, as well as on account of the defects of the system, the assignment of convict labour to private employers was limited in 1839 and abolished in 1841; meanwhile transportation to New South Wales was discontinued. It was hoped that the scarcity of labour resulting from the lack of convicts and from the rapid inflow of capital would be met by free immigration; this was conducted both under government control and on a bounty system, about 75,000 immigrants reaching the colony in the later thirties. Unfortunately a severe drought in 1839 was followed by a financial crisis, resulting from over-speculation in land; but, though unemployment was rife in the towns, immigrants were usually unwilling to go far inland, especially as the rate of wages offered by the squatters was very low. The squatters for their part attempted to force through the legislative council an arbitrary masters and servants amendment act; failing in this, because of official opposition, they again turned their attention to the possibility of obtaining Indian or Chinese coolie labour, and organized a Coolie Association in September 1842. This move was neither sanctioned nor encouraged by Gipps, who was strengthened in his attitude by the known opposition of the colonial office to an extensive importation of Asiatics. The labour issue led to a general shifting of class distinctions from a social (exclusive *v.* emancipist) to an economic basis, and Wentworth stood as a squatters' candidate at the election of June 1843 for the first representative council. There was no effective opposition at the poll, the franchise qualifications being too high for a strong democratic party; and the 12 official nominees found themselves confronted by 24 elected members, most of whom represented the powerful landed interest. Thenceforth Gipps was in continual disagreement with his legislative council, whose chief spokesman was Wentworth, already embittered against the governor for disallowing a claim to a large part of the south island of New Zealand (q.v.) when in 1840 the latter was formally annexed as a dependency of New South Wales.

The most serious causes of contention were the land regulations and the control of the land fund. By the British crown land sales act of 1842, land throughout Australia must be sold by auction at a minimum price of £1 an acre, the governor having power to increase this minimum for land close to township areas; Bourke's system of squatting licences was also sanctioned with modifications. The fund into which purchase-money and licence fees were paid was retained under control of the governor as representing the crown, to which colonial lands still belonged. The new council strongly opposed both the increase in the price of land and the provision in the licensing regulations which demanded a separate licence for each run instead of allowing several runs to be held under a single licence. But their chief object of attack was the governor's control of the land fund. Gipps was empowered by the colonial office to spend half this fund on assisting immigration, and the other half on the care of the aborigines, the construction of roads and bridges outside the settled districts, the maintenance of a border police force in the back country, and similar objects; any surplus was to be paid into the general revenue of the colony, which the council controlled. Wentworth demanded for the council control of the whole fund, and talked loudly of 'taxation without representation;' Gipps naturally defended the British position. There was trouble, too, over district councils. The act of 1842 provided for the establishment of district councils, which were to take over from the central government local roads, bridges, etc., paying expenses by means of rates levied in the district; but this instalment of local government was complicated by a provision that district councils should pay half the cost of the police, though the governor retained full control over that force. This provision further involved payment by the colony for the control of convicts who misbehaved after transportation, and the council contended that such expenses should be met from the British revenue. Consequently Gipps could do little towards the establishment of local institutions; and the squatter party, strengthened by the organization of a pastoralists' association, continued to oppose him until he left the colony.

While Gipps's firm rule antagonized the landed interests, it was hardly more satisfactory to the new immigrant group that was with difficulty organizing itself into a democratic party. Many immigrants had been members of Chartist associations in England, and had come to the new colony to find 'ample room to live in.' To their disappointment, the price of land had been raised beyond their powers of purchase, the financial crisis led to much unemployment in the towns, and opportunities offering in the country were not attractive. Gipps was not particularly sympathetic. He established a labour bureau, and developed certain public works, but ignored the immigrants' chief request—a return to the system of free land-grants on a community-settlement scale. As this, in the opinion of the radical leaders, provided the only means of escape from economic dependence, a Mutual Protection Association was formed in 1843 'by men robbed of their birthright, the franchise, holding their lives, liberties and properties at the will of the privileged classes.' The association lapsed, however, when the economic depression ended, and the 'new men' remained politically inactive until 1848.

Gipps had much to do besides withstanding his council. The residents of the Port Phillip

district, aggrieved at the remoteness of their administrative authority, demanded a separate government. The concession of representation by six members in the Sydney council did not appease them, for their business men could not spare time to attend the sessions. In 1844 all six members were residents of Sydney. When a motion for separation, proposed by one of the latter, was defeated in the council, they determined to apply direct to the colonial office, and Gipps strongly supported their contention. The governor was also burdened with aboriginals' complaints and misbehaviour. He knew that the colonial office had been giving anxious attention 'to the adoption of some plan for the better protection and civilization of the native tribes;' but he soon realized 'the extreme difficulty of devising any measure that shall effectually check the outrages which . . . are now of frequent occurrence beyond the boundaries of location' —outrages perpetrated both by settlers and by natives. One of his early duties was to order an inquiry into the conduct of a band of mounted police who, under shelter of their official position, had killed a number of aboriginals. Before the inquiry was complete, a particularly horrible outrage occurred, involving the massacre of between 40 and 50 friendly natives encamped on a cattle-station. Eleven white men were arrested and taken to Sydney for trial, seven being convicted and four acquitted. Mr. Justice Burton sentenced the seven to death, whereupon a great outcry arose among a section of the public 'who had become so accustomed to the common practice of shooting down the blacks in remote regions that they received a shock when that practice was treated as murder.' Gipps sent the men to the gallows, and outrages became less frequent—but the governor was more unpopular than ever.

During Gipps's term of office much valuable work was done in opening up the country; this is narrated in EXPLORATION BY LAND under the names of Strzelecki, Leichhardt, Mitchell, and Kennedy. The discovery of gold in these years by Strzelecki and Clarke is discussed under GOLD, DISCOVERY OF. But local politics—the training of New South Wales politicians for fuller self-government and the mastering of the over-hasty and unruly—was Gipps's chief concern; and, when in 1845 a new ministry in Great Britain adopted an entirely new attitude towards the colonies, it became time for him to retire. He had spent weary years in upholding against Wentworth and Lowe the authority of the colonial office which he served. But in 1846 the colonial office was intent on relieving itself of responsibility, even ready to give Australia its independence if asked for. Worn out and very ill, Gipps applied for permission to retire, and on 11 July 1846 sailed for England. Reverting to military employ, he was given command of the engineer depot at the Tower Hamlets, but before he could take it over died on 28 February 1847. (Kt. Bach., 1835.)

Gladstone Colony, THE. When in December 1845 W. E. Gladstone became secretary of state for the colonies he found that the disposal of convicts sentenced to transportation was an urgent problem; transportation to New South Wales had ceased, and Tasmania would soon be overfull. His predecessor, Lord Stanley, had envisaged a new penal settlement in the uninhabited northern regions of Australia, and Gladstone was attracted by the idea. First of all, however, he asked Fitzroy, then governor of New South Wales, for an expression of opinion on the resumption of transportation to New South Wales. Fitzroy published the despatch; a committee of the legislative council approved (guardedly) of the proposal; but the majority of the colonists showed themselves bitterly opposed to it. Gladstone thereupon proceeded with the foundation of a new northern colony, and selected Lieutenant-colonel George Barney (q.v.) as superintendent. The territory allotted to the colony was all New South Wales (as it then was) north of 26° S. lat., and its original population was to consist of emancipists and 'exiles' (i.e. prisoners released from English gaols on condition they accepted deportation to a colony for the rest of their sentence). The immediate procedure, said Gladstone, must include

(1) The selection of the best spot for a harbour, and for the town which might be expected to grow up in that locality.
(2) The immediate reservation there of such water frontage as ought to be open to general use, and of any sites which might appear requisite for public buildings or works of defence.
(3) The prompt distribution of the adjacent country into a sufficient number of lots to meet any probable demands of incoming settlers.
(4) The exception from such lots of any lands likely to be wanted for roads or other public purposes.
(5) The designation of the size of lots for the use of the two principal classes of settlers, and the manner in which the survey of both should proceed.

The name proposed for the settlement was 'North Australia.'

Barney reached Sydney on 15 September 1846, examined the coast of his new colony, and without much trouble decided that Port Curtis—a better if less picturesque harbour than Port Jackson—should be the site of his capital. Returning to Sydney, he chartered the barque *Lord Auckland*, which on 8 January 1847 sailed from Port Jackson with the pioneers of North Australia. They comprised Barney himself and his family; W. W. Billyard, chairman of quarter sessions; J. S. Dowling, crown prosecutor; E. C. Merewether, colonial secretary; G. H. Barney, clerk; assistant commissary-general Darling; Captain Day of the 99th regiment and his family, with 22 soldiers of the regiment; and about 40 civilians. The *Lord Auckland* was followed on 26 February by the barque *Thomas Lowry*, with several more families and 50 soldiers. On 25 January the *Lord Auckland* ran on a shoal at the entrance to Port Curtis, but was floated off on the 31st. On 30 January Barney and the other officers (who had landed soon after the vessel struck) were sworn in; an executive and a legislative council were proclaimed, and Captain Day was appointed police magistrate. The first days of the new settlement were not happy. 'We have three great evils,' wrote one of the pioneers, 'to contend with here—excessive heat, heavy rains and mosquitoes in millions, particularly in wet weather. We are thus in constant misery.' But relief was at hand. On 3 July 1846 Earl Grey had succeeded Gladstone as secretary for the colonies, and one of his first acts was to reverse the policy of his predecessor in regard to North Australia. On 15 November he wrote to Fitzroy intimating that the government had decided to abandon the newly-formed colony; Barney and his officers were to be recalled and employed in New South Wales. On 7 April 1847, therefore, the *Kangaroo* brought to the new settlement the news of its abandonment, and on 9 May the *Thomas Lowry* returned to Sydney with

a number of the officials and settlers. A memorandum from the audit office at Sydney, dated 31 March 1848, sets forth the cost of this short-lived colony as over £15,000.

Although the colony was wiped out of existence, the town of Gladstone grew up on the site of the experiment, and in 1854 Sir Maurice Charles O'Connell (q.v.) was appointed government resident, retaining the post until the colony of Queensland came into existence in 1859.

See J. F. Hogan's *The Gladstone Colony* (London, 1898.)

Globe-fish. See TOADOES.

Glover, JOHN (1767-1849), born at Houghton-on-the-Hill in Leicestershire on 18 February 1767, was the son of an agricultural labourer. His education was limited, and of art training he had none: but he taught himself to draw and paint, and in 1794 set up as a drawing-master at Lichfield. From 1795 onwards he exhibited at the Royal Academy; in 1805 he moved to London, was an original member of the Society of Painters in Water-colours (of which he was president in 1815), and before 1813 had become one of the most fashionable drawing-masters in the metropolis. After the restoration of the Bourbons in 1814 he visited Paris and gained the favour of both Louis XVIII and Louis Philippe, then Duke of Orleans. In 1824 he was a founder of the Society of British Artists. When he decided to retire from the active practice of his profession, he at first contemplated settling down on Ullswater in the Lake District, but finally decided to migrate to Tasmania: Louis Philippe commissioned him to paint pictures of Tasmanian scenery, but it is not known whether this was the reason for his decision. He reached Launceston on 18 February 1831, and settled —at the age of 64—on the northern slopes of Ben Lomond on a station which he named Patterdale. It is said that he and John Batman, in company, were the first Europeans to reach the summit of Ben Lomond. In 1835 he sent to England the pictures for Louis Philippe and several others, which were exhibited in London. He continued to paint until his death on 9 December 1849.

Glynn, PATRICK MCMAHON, born at Gort in Ireland on 25 August 1855, and educated at Trinity College, Dublin (B.A. and LL.B., 1880), was called to the Irish bar in 1880, but at once migrated to Australia and was admitted to the bar in Melbourne. Moving to South Australia in 1883, he was admitted to the bar in Adelaide in that year, and subsequently to the bar in Sydney. For about ten years he wrote for the Kapunda *Herald* and the Adelaide press, and in 1884 composed for the South Australian Land Nationalization Society a manifesto that stirred C. C. Kingston (q.v.) to bring in his bill for direct taxation on unimproved land values. In 1887 he was elected to the assembly as member for Light, but lost the seat by a few votes in 1889; from 1895 to 1901, with the exception of a few months, he was member for North Adelaide. In December 1899 he was attorney-general in the short-lived Solomon ministry. Always a supporter of inter-colonial federation, on which he wrote several pamphlets, he represented South Australia in the convention of 1897-8, and in 1901 was elected to the federal parliament from his State; in 1903 he became member for Angas in that parliament, and retained the seat until December 1919. In federal politics he took an independent part, following no particular leader, but was attorney-general in the coalition ministry of 1909-10, minister for external affairs in the Cook ministry of 1913-4, and minister for home and territories in the 'national' war ministry of 1917-20. Outside politics he has interested himself chiefly in constitutional law, in the disposal of the Murray waters (see IRRIGATION), and in the study of Shakespeare.

Gmelina, a genus of the family Verbenaceae, consisting of trees or tall shrubs with opposite leaves, and extending from the Caspian Sea to New South Wales. The flowers are often large, pink, pale purplish, or blue in colour; calyx 4-5 toothed or lobed; corolla-tube dilated upwards, the two upper petals sometimes united in a lip; stamens 4, in pairs, shorter than corolla; fruit a succulent drupe. *G. Leichhardtii* (White Beech), found in eastern Australia, is a tree 80-100 feet high with a diameter of 2-4 feet. It has handsome flowers, white with purple markings. The timber is strong, durable and easily worked; if moderately seasoned it does not unduly contract or expand, and is therefore valuable for decking vessels, flooring verandahs, etc. The fruits ('beech-nuts') are, when approaching maturity, frequently attacked by insects which destroy their fertility. This factor, in conjunction with the hardness of the seeds, reduces the productivity of the plants to such an extent that in certain districts the species is within measurable distance of extinction. *G. macrophylla*, occasionally known as Queensland Beech, is a tall tree with a prominently marked sapwood of a pretty purple colour.

Gnaphalium, a widespread genus of the family Compositae, consisting mostly of herbs with a coat of cottony down, known as cudweeds or cudworts. The flowers are rayless; floral bracts shining, in several rows; seeds oblong, with a pappus of capillary bristles. *G. purpureum* has a lax growth and flaccid leaves. The seeds are crowned by a comparatively large parachute of bristles; this, however, is not used for their dispersal, as the bristles are united in a ring by their bases and become detached from the fruit before the seeds fall.

Gnow. See MOUND-BIRDS.

Goanna. See LIZARDS.

Goat-fish or **Red Mullet,** members of the family Mullidae; a number of closely allied species of this family are known from Australian waters, and several are not uncommon, but they are not plentiful in the markets. They have two fleshy barbels beneath the chin, which have been likened to a goat's beard; these serve as tactile organs, and the young fish may be observed round wharf-piles with these members extended forward, feeling among the marine growths. All the family is richly coloured with brilliant reds and yellows, and with blue streaks and spots which scintillate as the fish struggles in its death-throes. It was fashionable among the Romans to have the fish brought alive into the dining hall, so that guests could feast their eyes upon its gorgeous and changing hues during the dying agonies. Red mullets have no affinity with the grey mullets (Mugilidae). A.R.McC.

Gobies, a very large group (Gobiidae) occurring in almost all waters, but usually of

such small size as to be commonly regarded as the young of larger species, or as too insignificant to merit attention. Their ventral fins are united to form a sucking-disk, by means of which they cling to stones, etc. They vary greatly in form and, occurring in both salt and fresh water, are modified to suit the diverse conditions of life on coral-reefs, sandy and muddy bottoms, estuaries, rivers, and even the isolated waterholes of central Australia.

A minute fish (*Gobius lidwilli*), plentiful around oyster-covered rocks near Sydney, is full-grown when little more than half an inch long, and bears the distinction of being one of the smallest vertebrate animals known. Some tropical and brightly coloured species of the genus *Gobiodon* are common among the branches of living corals, wherein they find shelter from their enemies; though they move with alacrity, they are so specialized to their strange environment as to become helpless when removed from their hosts. Over 50 species of gobies have been described from Australian waters. The mud-skipper (q.v.) is another member of the family. A.R.McC.

God-fern. See FERNS.

Gold. The discovery of gold in Australia—possibly the most epoch-making event in its history—is treated of in a separate article. Here are discussed the distribution of the precious metal throughout the Commonwealth, its chief modes of occurence, and the yields in recent years.

In the early years of gold-mining most of the gold was obtained—as might be expected—from alluvial deposits in shallow ground. When these were exhausted, resort was had either to deep leads—the beds of Pliocene and Pleistocene drainage channels, which still carried alluvial gold—or to auriferous reefs (usually of quartz) and to deposits of ironstone or of impregnated slate, tuff, etc. In New South Wales the beach sands of the northern coast, from Port Macquarie to the Queensland border, have yielded much gold in association with platinum and tin. The chief New South Wales fields have been Cobar (quartz) and the dredged areas of Adelong, Gundagai, and Araluen; this State produced its maximum in 1852, and of late years has yielded less than 7 per cent of the total Commonwealth production. Victoria, which produced its maximum in 1856, and for the 10 years 1852-61 averaged over 10 million pounds' worth a year, accounts for about 17½ per cent of the Commonwealth total; the famous Ballarat field has practically ceased to exist, and the chief producing districts are Bendigo (quartz), Beechworth (mainly quartz, but including a dredged area along the Ovens), and Castlemaine (mainly quartz). In the Bendigo district are the deepest mines in Australia, with shafts 4614 and 4318 feet deep. Queensland, whose annual output of late years has been about twice that of New South Wales, has depended almost entirely on the Mount Morgan field, which is separately described; alluvial deposits hardly exist, and the quartz reefs of Charters Towers, Chillagoe, and the Etheridge have either pinched out or do not pay for working. In South Australia the deposits, such as they are, are almost entirely alluvial, but this State has not produced in 70 years half as much gold as Western Australia yielded in 1920 alone. Tasmanian mining is almost entirely concerned with quartz reefs, though in the north-west a good deal of gold is won from copper ores. In Western Australia alluvial gold is now almost unknown. On the Yalgoo and Pilbara fields deposits of gold have been found in conglomerates of Cambrian age; but the principal auriferous rocks are probably pre-Cambrian and possibly Archaean, and in the lodes which they contain the gold is associated with pyrites of iron, copper, and arsenic, and sometimes with tellurium. The East Coolgardie field (i.e. Kalgoorlie and Boulder) has for a long time been by far the most productive, the Mount Margaret (Leonora and Laverton), Murchison, and Yilgarn fields lagging some distance behind; in 1921 East Coolgardie was responsible for over 70 per cent of the whole Western Australian yield. Native gold obtained from this field has been found 99.91 per cent pure.

Taking the Commonwealth as a whole, there have been two great periods of gold-production—1852-60, when the annual value of the yield averaged over 11½ millions sterling, and 1898-1911, when the annual average value was about 13¾ millions; in the first period Victoria produced about 87 per cent of the total, in the second Western Australia produced about 50 per cent of it. Since 1911 Western Australia has yielded over 60 per cent of the Commonwealth's total; during the same period Australia's proportion of the world's production has decreased from 11 to less than 5 per cent. The following figures (the latest available) are relevant:—

Gold won.	1922 fine oz.	Average 1912-21 oz.
New South Wales	25,222	101,524
Victoria	106,872	266,743
Queensland	80,584	191,753
South Australia	1,000	5,412
Western Australia	538,246	985,366
Tasmania	3,431	17,625
Northern Territory	115	1,560
Commonwealth	755,470	1,569,983

In New South Wales about 46 per cent of the yield comes from alluvial sources, nine-tenths of that being dredged. In Victoria 19½ per cent is alluvial, of which more than half is dredged. In the other States practically all the yield is from reefs or impregnated deposits.

Gold, Discovery of. The first authenticated discovery of gold in Australia is that of assistant-surveyor James McBrien, who recorded in a field-book (still in existence) on 15 February 1823 that near the Fish River between Rydal and Bathurst (N.S.W.) he found 'numerous particles of gold in the sand on the hills convenient to river.' In 1839 Strzelecki (q.v.) discovered auriferous pyrites near Hartley, just beyond the Blue Mountains. He furnished a report to the government on the subject, but stated that the pyrites yielded a very small proportion of gold, sufficient to attest its presence, insufficient to repay its extraction. Gipps asked him to keep the matter secret 'for fear of the serious consequences which, considering the condition and population of the Colony, were to be apprehended.' In a letter to Thomas Walker of Sydney, dated 16 October 1839, and published in the *Sydney Morning Herald* of 17 May 1851, Strzelecki wrote:—'On this side of the Dividing Range the variety of rocks and embedded minerals augment; indications most positive of the existing gold and silver veins are met with. The want of means however—that is, time and men—did not allow me to trace them to their proper sources. Why has the Government not sent heretofore a man of science and mineral-

ogical and mining acquirements to lay open these sources of wealth still hidden beneath, and which may prove as beneficial to the State and individuals as the rest of the branches of Colonial industry.'

On 13 and 14 February 1841 W. B. Clarke (q.v.) discovered gold in quartziferous slates in the main range west of Sydney, near the heads of Cox's River and the Winburndale rivulet. In 1842 he found gold on the Wollondilly; the next year he announced his discovery to various members of the legislature, and shortly afterwards made it known generally. On 9 April 1844 he reported the matter to Gipps, and showed him the gold; but again the governor was afraid of the consequences, and decided that it would be better to put the gold away. A shepherd named Macgregor found gold in the Wellington district in 1843-4, and Sir Thomas Mitchell took to England in 1847 a piece of quartz and gold brought to Sydney by this man.

Sir Roderick Impey Murchison in 1844 examined a collection of rock specimens brought from Australia by Strzelecki, and pointed out their likeness to the auriferous rocks of the Ural Mountains. In 1846 he wrote: 'I now learn however that fine specimens of gold have been found in the western flank of the Australian Cordillera, particularly at the settlement of Bathurst where it occurs in fragments composed of the same matrix (quartz rock) as in the Ural. My friend and associate at the Imperial Academy of Petersburg has recently suggested that a careful search for gold in the Australian debris will, it is probable, lead to its detection in abundance. I therefore encouraged the unemployed Cornish miners to emigrate and dig for gold.' These remarks, when circulated in Australia, encouraged a certain W. J. Smith, who was promoting iron-works near Berrima and wished to advertise the district, to send Murchison in 1848 some specimens of gold. In 1849 Smith exhibited to the colonial secretary a lump of gold embedded in quartz, and offered to show the government where he had found it if previously rewarded by the payment of a large sum. 'The obvious reply to his offer' as Fitzroy told Earl Grey, 'was that the Government could enter into no blind bargain on such a subject but that if Mr. Smith thought proper to trust to the liberality of the Government he might rely on being rewarded in proportion to the value of the alleged discovery, when that was ascertained. Mr. Smith refused to accede to the proposal and there the matter rested' (Despatch of 11 June 1851). The despatch says further: 'On the 3rd of April 1851 Mr. E. H. Hargraves, who had recently returned from California, addressed a letter to the Colonial Secretary to the effect that, having occupied himself for two months in exploring a considerable extent of country, in which, from his experience in California he was led to believe gold was to be found, he had prosecuted his speculation to a successful issue and offered to point out the localities where he had discovered gold to any officer the Government might appoint, on condition that the Government would award him the sum of £500 as compensation.' To this suggestion a similar answer was given, and Hargraves on 30 April expressed himself quite satisfied to leave the remuneration to the liberal consideration of the government, and disclosed the localities as '"'Lewes Ponds and Summer Hill Creeks,' 'M'Quarrie and . . . . . Rivers' in the districts of Bathurst and Wellington."' For the full account of Hargraves's discoveries see the article under his name.

The government geologist, Samuel Stutchbury, was then instructed to make a thorough examination of these localities, and on 14 May forwarded a report to the colonial secretary confirming the discovery. The news spread with amazing rapidity, and prospecting operations were immediately commenced all over the country with the result that a number of the principal goldfields were discovered the same year. This was an epoch-making event in Australian history, as a reference to the population figures prior and subsequent to the year 1851 amply demonstrates:—

Population of Australia,

1841	220,968	1851	437,665	1855	793,260
1850	405,356	1852	513,796	1858	1,050,828

Thus, while the average increase in population from 1841 to 1850 was about 20,000 yearly, the increase in 1851 was over 32,000, that in 1852 over 86,000, in 1853-5 over 93,000 yearly, and in 1856-8 nearly 86,000 yearly.

The Hargraves goldfield was one of the first to be discovered, and there in July 1851 the celebrated Kerr's Hundredweight (a mass of gold weighing 106 pounds) was found by an aboriginal shepherd in the outcrop of a quartz reef. Immediately afterwards a rush took place and extremely rich alluvial deposits were discovered. For a considerable period between 4000 and 5000 ounces of gold are said to have been sent away from the field every fortnight. Other important discoveries were made at Araluen (1851), Lambing Flat near Burrangong (1860), Lucknow near Orange (1863), Hill End (1872, though alluvial gold was known there much earlier), Yalwal (1873), Hillgrove (1888—but diggers had been on the field for many years before) and Wyalong (1893).

Victoria. In 1844 a man named Smyth thought he had discovered gold in Victoria near the Ovens River, and reported it to Superintendent Latrobe, who advised him to say nothing about it. Gold said to have been found by a shepherd in the Pyrenees Range was exhibited in a jeweller's shop in Melbourne in January 1848, and this induced C. Brentani (who had purchased the gold) to accompany the shepherd back to the Pyrenees: a number of diggers also went, but all failed in their search, and it is probable that the shepherd was an impostor. In 1849 auriferous quartz was found at Smythesdale, but nothing seems to have been done until after the discovery of the Bathurst and Turon workings in New South Wales, when apprehensions that the population of Victoria might drain off to the New South Wales diggings caused a committee to be formed in Melbourne on 9 June to promote the discovery of a goldfield in Victoria. In March 1850 W. Campbell of Strath Loddon found on the station of Donald Cameron of Clunes several minute pieces of native gold in quartz. This was concealed at the time, lest its announcement should bring undesirable strangers to the run; but on 10 June 1851 Campbell disclosed it. In the latter part of June a party headed by Louis John Michel discovered gold in quartz rock at Anderson's Creek, and on 16 July they brought to town a sample of alluvial gold from the same locality. On 1 July James Esmond, who had returned a few months earlier from California, obtained gold in the quartz rocks of the Pyrenees, near Cameron's station. Dr. George H. Bruhn—a German physician—had already found

indications of gold in quartz in April about two miles from Parker's station, and at Cameron's station had been shown specimens of gold from an area known later as the Clunes diggings.

Thomas Hiscock, a resident of Buninyong, on 8 August 1851 found auriferous quartz on the Buninyong ranges, in the gully now bearing his name, and communicated the fact to the editor of the *Geelong Gazette* on the 10th; this attracted great numbers of diggers to the neighbourhood, and so led to the discovery of Ballarat. The discovery of Golden Point is claimed by two parties, Turner's on 24 August and that of Connor and Brown on the 25th; the latter received official recognition. The first find at Mount Alexander is claimed by Christopher Thomas Peters, then a hut-keeper at Barker's Creek, who found gold on 20 July at Specimen Gully. On 1 September John Worley, a member of his party, 'to prevent them from getting into trouble,' published an account of their workings in one of the Melbourne journals. The Gold Discovery Committee awarded £1000 to Michel and his party; £1000 to Hiscock as the substantial discoverer of the Ballarat deposits; £1000 to Campbell as the original discoverer of Clunes; £1000 to Esmond as the first actual producer of alluvial gold for the market; and £500 to Dr. Bruhn in acknowledgment of his services in exploring the country and diffusing the information of the discovery of gold. They also recommended a grant of £5000 to Hargraves and of £1000 to W. B. Clarke. But these were recommendations only; Hargraves never received more than £2381, Campbell £476, and the rest got their rewards partly in 1855 and partly in 1861. The discovery of gold was all-important to Victoria, which was at the beginning of 1851 merely a pastoral settlement with a population of 77,345.

Immigrants now began to pour into the colony, and the story of the next few months can be best told by Latrobe. On 10 October he wrote to Earl Grey:

> Within the last three weeks the towns of Melbourne and Geelong and their large suburbs have been in appearance almost emptied of many classes of their male inhabitants; the streets which for a week or ten days were crowded by drays loading with the outfit for the workings are now seemingly deserted. Not only have the idlers . . . . and day labourers in town and country . . . thrown up their employments and run off to the workings, but responsible tradesmen, farmers, clerks of every grade, and not a few of the superior classes have followed. . . . . Cottages are deserted, houses to let, business is at a standstill, and even schools are closed. In some of the suburbs not a man is left, and the women are known for self-protection to forget neighbours' jars, and to group together to keep house. The ships in the harbour are in a great measure deserted: and we hear of instances where . . . . even masters of vessels, foreseeing the impossibility of maintaining any control over their men otherwise, have made up parties among them to go shares.

By the official figures at the time the amount of gold raised between 1 August 1851 and 6 December was:—

	Ounces
In banks at Melbourne	90,000
„ „ Geelong	30,000
Shipped, including 26,734 oz. already on the *Hero*	31,734
On the ground in merchants' or private hands	60,000
Total	211,734

At £3 per ounce that was worth £635,202.

Another despatch from Latrobe, dated 19 December 1851, says:

> The interval has been one of intense excitement in the community, and in effect this still continues. . . . The gold raised upon the Mount Alexander goldfields is now calculated by hundredweights, and arrives in the cities . . . . at the rate of probably two tons per week; so it has been at least for the last two weeks. Some 20,000 individuals are calculated to be congregated at the principal fields in that quarter, now four in number. . . . Since I last wrote the upper workings on Forrest Creek, prolific as they are, have been found equalled by others down the valley to its junction with Barkers Creek. . . On Friars Creek, five miles to the westward, an equally rich field has now been two or three weeks in working; and within a short period another ground at Bendigo Creek, to the north-east, on a branch of the Campaspe . . . . has been entered upon. Right and left throughout the whole region gold is found to exist. . . .

An official report rendered to Latrobe on 29 December states:—

> The Postmaster apprehends an entire disruption of the business of his Department, unless remedial measures can be taken. The Surveyor General is of a similar opinion. The Deputy Registrar thinks that all his subordinates will leave their occupation. The Supt. of Police states that, though in accordance with authority he offered high rates of pay to his force, fifty out of fifty-five constables have determined to go to the gold-fields; but his clerk and chief constables will remain. . . . The Crown Solicitor apprehends complete embarrassment. The Denominational School Board fears loss of teachers.

To prevent a complete disruption of the public service, increased rates of pay in all departments were promptly voted.

The general dislocation of society and of the whole machinery of the government was intensified in 1852 by the discovery of extensive goldfields in the remote Ovens district, the sudden rush of 20,000 to the McIvor and the creation of the town of Heathcote. The maintenance of order in the mining districts was, owing to the want of officials and the number of wild and lawless men who flocked to the diggings, almost impossible. By the time, says Turner, that Latrobe had made arrangements for police protection at Clunes, it was deserted in favour of Buninyong; as soon as a staff was organized for that place, the diggers flocked to Ballarat; and before the machinery could be got in order there, the thousands had melted to hundreds, and the process had to be commenced afresh at Forest Creek. Thence they streamed away to Bendigo, and out over the dry northern plains to Mount Korong, or on the west to Avoca and the Pyrenees, and on the east to the McIvor and the tributaries of the lower Goulburn. Meanwhile from the remote districts on the upper Murray, and the mountain fastnesses of Omeo, came tidings of swarming adventurers from the adjacent territory of New South Wales overrunning the land, gathering golden spoil, and refusing allegiance to Victorian authority. No wonder that the harassed governor had already informed the colonial office that however suitable the licensing system might be to the conditions of New South Wales, whence it was adopted, 'it never can be fully or satisfactorily carried out in this colony.' Yet he adds: 'While the Council is fully disposed to condemn the present licensing system, according to which the man who takes thousands from the ground and the man who is totally unsuccessful are presumed to pay alike, it is scarcely inclined to lend efficient aid to the collection of

a royalty upon the actual amount of gold realized by the successful adventurer.'

This licence fee, instituted in New South Wales in May 1851 and proclaimed in Victoria on 18 August, was first fixed at 30s. per month and afterwards reduced to 30s. per quarter. It was little felt as a hardship at first, when diggers were not numerous and generally successful; but, as time went on and the goldfields' population increased, many men were unsuccessful and payment became burdensome. The burden was increased by the methods of collecting it, which were too often objectionable; and the dissatisfaction and discontent culminated in a riot at Ballarat towards the close of 1854, described under EUREKA STOCKADE.

A royal commission subsequently recommended the abolishing of the licence fee, and made other concessions, the carrying out of which restored peace and harmony. Then the real good of the gold discoveries began to be realized; the population already mentioned as 77,345 in 1851 had increased to 231,925 in 1854, and in 1857 had reached 410,766.

Queensland. In 1853 Samuel Stutchbury, the government geologist of New South Wales, found gold near Port Curtis at the Calliope; this was the first authenticated discovery of gold in Queensland. Little appears to have been done, however, until in August 1856 a shepherd on Canning Downs brought in from 'Lord John's Swamp' 8 dwts. of gold. Gold was also found in that year at Emu Creek on the way to Gympie. But it was not until 1858 that payable gold was struck at Canoona (near Rockhampton) by an enterprising Cornish miner named Chapple. These alluvial deposits soon worked out, and the rush was attended with disastrous consequences. About 1862 residents at Gayndah offered a reward of £2000 to anyone who would find a payable goldfield, and it soon became known that in the country east from Eidsvold and Rawbelle alluvial gold could be got out in wet weather. At Ridgelands (about 21 miles from Rockhampton) a field was opened in February 1867—the discoverers received £250, the first reward of the kind ever paid in Queensland —and Ridgelands had hardly been opened before gold was discovered at Rosewood, where a patch of nuggets was found just below a slate bar.

Still, no really important discovery was made until in October 1867 a prospector named James Nash, making his way from Nanango to Maryborough, obtained several ounces of gold in a gully near what is now Gympie. Public announcement of his success being made on 16 October, hundreds of persons rushed to the new goldfield (Nashville, as it was then called), and with the discovery of a quartz reef on 8 November began the permanent prosperity of the field. In 1869 gold was found on the Gilbert River, and the Gilbert, Etheridge, and Woolgar fields were proclaimed; and on 26 January 1872 Hugh Mosman took up the first claim at Charters Towers. Other fields have followed—the Palmer, inland from Cooktown, in 1873, the Hodgkinson in 1875, Mount Morgan (see MORGAN, F. A.) in 1882, Croydon in 1886, the Hamilton field in 1899, and the Alice River in 1904.

South Australia. South Australia has the honour of having what is believed to have been the first authentic discovery of gold in Australia from which actual mining operations resulted. This took place in January 1846, about 10 miles east of Adelaide. In the early part of 1852 W. Chapman found very rich surface gold on the side of a hill above Donkey Gully; it was traced to Chapman's Hill, and found at the foot of a tree where it had been laid bare by the dripping of water from the branches. Half an ounce was picked up by dry fossicking, and on the following day several ounces were washed from the root of this tree. An offer of £10,000 reward for a payable goldfield had been published in the *Gazette* of 18 December 1851; the conditions were that licences (at that time costing 30s. each) to the value of £1000 must be taken out in the first two months, and that £10,000 worth of gold must be found in the same time. As Chapman could not prove that the second condition had been complied with, the executive council granted him and his friends £500.

About 1871 £200 and £300 were paid for discoveries of gold at Jupiter Creek. Gold has also been found in scattered patches along the main range from Echunga to Olary. The Teetulpa goldfield was discovered on 6 October 1886, and £300,000 worth of gold was obtained in an area of about a square mile; but the ground was soon worked out. A fair amount of gold has been won from reefs at Tarcoola (300 miles north-west of Port Augusta), and discoveries have been reported from the Peake and Denison ranges.

Northern Territory. In 1872 gold was found in payable quantities by the northern contractors for the overland telegraph line. Arltunga was the scene of a reported rich find in 1902, but the yield has since been small. In 1908 Driffield was the centre of production, and in 1909 a new field was proclaimed at Tanami, 450 miles south-east of Wyndham.

Tasmania. Fenton, in his *History of Tasmania*, says that before the Californian discovery a convict at Port Arthur offered to show a deposit of gold, but 'the Governor discountenanced the revelation, as he did not consider the colony ripe for such a discovery.' As far back as 1824 a man named Cobb, working in a road party at George Town, is said to have given Captain D'Arcy, then magistrate, a piece of metal; D'Arcy pronounced it brass, but Arthur gave Cobb a corner block in Launceston as a reward. Another authority speaks of gold having been traced near Nine Mile Springs (Lefroy) in 1849 by a resident of Launceston named Riva. The first important discovery seems to have been made about 5 February 1852, when Kicling Richardson, a shepherd, found gold in an alluvial deposit four miles from Fingal. Shortly after this Governor Denison prohibited the unauthorized taking of any gold metal or ore containing gold, and the digging and disturbing of the soil in search of gold. Small finds were also made at Tower Hill Creek and Nine Mile Springs, and in 1859 James Smith found gold at the Forth, and Peter Leete at the Calder. The quartz reefs of Fingal and Waterhouse came into prominent notice in 1869. These discoveries led to the appointment of two gold commissioners and the proclamation of two townships on the northern coast, Ducane and Lyndhurst. The Waterhouse reefs began to produce gold in 1871, but soon petered out and were abandoned. In 1877 the Tasmania gold mine was opened at Beaconsfield. But, though this mine has been successful, and discoveries have been made at Mangana (1870), Lisle (1878), Branxholm (1883), and other fields—including Mount Lyell (1886), more famous for its copper—none have been in any way extraordinary.

Western Australia. In the latter part of 1852

three or four parties were despatched east of York and Newcastle to seek for gold, but from climatic causes they were forced to abandon their search when within a short distance of the now well-known Yilgarn goldfield. Rich specimens of gold-bearing stone were found in 1852-3 by shepherds and others who were unfortunately unable to locate afterwards the places from which the specimens came. In March 1854 there was a reported discovery of gold at Cardup, 25 miles from Fremantle, but A. C. Gregory found the metal to be yellow mica and iron pyrites.

In the latter part of 1861 F. K. Panter, an inspector of police, while on a trip east of Northam, picked up several specimens of gold-bearing quartz. In 1862 the government engaged E. H. Hargraves (q.v.) to search for precious minerals through the settled districts of the colony for six months. Landing at Albany he prospected as far as Northam and through the Darling Range, but made a very unfavourable report, declaring that the formation of the area was such that gold would never be found in large and payable quantities in that area. Undismayed by this report, Western Australians continued their search for many years. In the government *Gazette* of 20 July 1869 £5000 reward was offered for the discovery of a payable goldfield within 30 miles of any declared port of the colony, and in 1870 a report was current that gold had been found at Blackwood. In 1871 alluvial gold was found by a shepherd at Peterwangy on the upper Irwin; in 1872 specimens from Kelmscott, Newcastle and Baylup were assayed at the Sydney mint and found to contain gold; in 1873 a party of Ballarat miners was engaged to prospect for precious metals, and the government erected a quartz-crushing mill at Fremantle. In the same year a quartz reef was found at Kendenup near Albany, which by Melbourne assays contained over an ounce to the ton. But no field was permanently established (though in 1882 A. McRae, when riding from Cossack to Roebourne, picked up a nugget of gold weighing 14 oz.) until in 1883 E. T. Hardman, the government geologist, first visited Kimberley, and on his return reported the existence of auriferous country on the western side of the Leopold Range.

Steps were taken to organize and equip a party to prospect the Kimberley district, and in August 1884 the legislative council placed £1000 on the estimates 'to be expended in prospecting for the discovery of a gold field;' but before the party started miners from the eastern colonies (Hall and others) had already arrived in the north-west, and on 30 August left Yeeda station on a branch of the Elvire; thence they prospected the Margaret and Ord rivers, finding gold on each. Carr Boyd claimed to have discovered a rich reef, and sent several hundredweight of the stone to Melbourne before Hall appeared, but after examination the government awarded £500 to Hall and his party. On 20 May 1886 the Kimberley goldfield was proclaimed. In 1887 Riseley and others found rich reefs 30 miles from Golden Valley, at a place they named Southern Cross. Two promising reefs were opened up in 1888 at Mallina, east of Roebourne, and in July a rich alluvial find was made at Pilbara Creek. The Yilgarn and Pilbara goldfields were proclaimed on 1 October 1888.

The Murchison (Nannine) goldfield was brought into notice by H. P. Woodward, the government geologist of the day, and in August 1891 J. F. Connolly reported the discovery of alluvial. In April 1892 Arthur Bayley and John Ford, after selling gold which they had secured at the Murchison, left Perth on a prospecting expedition. After many wanderings and no success they headed for Southern Cross, purchased supplies for seven or eight weeks, and in course of time reached the native well at Coolgardie, where they camped. In the morning Ford picked up a ¼oz. nugget, and before dinner-time they found over 20oz. of gold. During the next three or four weeks they secured by specking and dry-blowing over 200oz., and then were forced to return to Southern Cross for further provisions. They said nothing of their discoveries, but hurried back, and on the first Sunday afternoon after their return found the reef which soon became famous throughout the mining world. That evening they picked up and dollied with a tomahawk from the cap of the reef over 500 ounces of gold, and early the next morning pegged out a prospecting area. Bayley made his way to Southern Cross with 554oz., which he exhibited to Warden Finnerty on 17 September. The field was declared open, and Bayley left Southern Cross for Coolgardie again, accompanied by a coach, by teams, and a host of horsemen. The news quickly spread. The *West Australian* of 21 September says 'In Perth and Fremantle everyone seems to be either carrying tents, picks, shovels, and dishes or otherwise preparing for the road.'

Kalgoorlie (Hannan's) was discovered in June 1893, by Flannigan and Hannan, who were on the road with a party of about 150 men to a new 'rush' 50 miles north-east of Coolgardie. The party camped two days on the unsuspected field, waiting for water teams; as rain fell, they started on their way again, leaving Hannan and Flannigan behind. Flannigan, while looking for their horses, found a couple of nuggets and induced Hannan to remain with him; in a few days they picked up over 100oz., and on 17 June Hannan went back to Coolgardie and applied for a reward claim. Bardoc (the 45-mile) was located in August, and 'Siberia' in October. In 1894 Hall and Speakman pioneered the Mount Jackson district; rich alluvial was found at the Pinnacles in February, but the chief discovery of the year was the Kanowna alluvial ground, found by a digger known as Old Tom.

Bulong (the I.O.U.) was discovered in May —by two hitherto unsuccessful prospectors who were returning to Perth—the Norseman field in July, and the Lady Shenton at Menzies in September. Two of the richest finds of 1894 were the Wealth of Nations and the Londonderry. The Londonderry find was made, quite by accident, in June by an unsuccessful prospecting party who were on their way back to Coolgardie; rich quartz was picked up by two of the party, and after a brief search the outcrop of a reef was exposed, from which during the first three or four days they took between 4000 and 5000-oz. One specimen, Big Ben, was estimated to contain £3500 worth of gold. The Wealth of Nations was found in July, by J. G. Dunn, an old prospector. He discovered the outcrop of a reef 28 miles from Coolgardie. On breaking into the cap the quartz appeared to be glittering with gold; one of the first pieces taken out contained fully 800oz., and in a few days he secured gold to the value of over £20,000.

1895 was also a busy year—it was reported in January that over 2500 diggers were dry-blowing in the vicinity of Kalgoorlie. The Yal-

goo goldfield was proclaimed in January; in February a valuable discovery was made at Niagara; and early in the year the Hands Across the Sea reef claim was located at Kunanalling. At the end of the year there were 11 batteries, one cyanide plant, and 12 other mills working in the Coolgardie district, 17 batteries at Cue, 9 at Nannine and 2 at Mount Magnet; while during the first half of the year 73 Western Australian mining companies were incorporated in London, not to mention those floated locally and in the eastern colonies.

The Donnybrook district was opened up by Bourke and Hunter in 1898; Jackson's Claim at Donnybrook, and the Merton's Reward Mine, in 1899; in 1900 gold was discovered at Yundamindera and Mount Higgins (North Coolgardie), Willcena (Peak Hill), Ninghan (Yalgoo), Boodalyerrie Creek (Pilbara), Canvell, Reedy's and Weld Range (Murchison), and Yellowdine and Dunladgin (Yilgarn).

The impetus given to the colony by the gold discoveries may be gauged by the following figures:—

Year.	Inhabitants.
1890	46,290
1900	171,022

an increase entirely due to the gold discoveries.

Shipping.	Tonnage.
1861	57,456
1871	63,922
1881	145,048
1891	533,433
1898	1,194,894

Principal Nuggets found in Australia.

Name.	Date of Discovery.	Place of Discovery.	Gross Weight.	Value.
			oz.	£
Kerr's Hundredweight	1851	Turon River (New South Wales) ...	1,272	5,000
Sarah Sands	1853	Canadian Gully (Victoria)	1,619	5,532

Holtermann's Nugget	1872	Hill End (New South Wales)	7,560	12,000

Kerr's and Holtermann's were not, technically speaking, nuggets, but masses of gold found *in situ* in reefs.

Golden Perch or **Yellowbelly** (*Plectroplites ambiguus*) is an important food-fish, abundant in the whole Murray-Darling river system, and in the cismontane rivers of northern New South Wales and southern Queensland. A few specimens have attained a length of two feet and a weight of over 14 pounds. Its capture affords fine sport to anglers, and its flesh is excellent eating. A.R.McC.

Goldsbrough, Richard (1821-1886), born at Shipley in Yorkshire in 1821 and apprenticed to a wool-stapling firm in Bradford, started on a small scale as a wool-merchant in 1842, became interested in Australia as a wool-producing country, and in 1847 migrated to Adelaide and then to Melbourne, and commenced business at the latter place in 1848. The remarkable wool-clips of 1850 and 1851 enabled him to improve his position in spite of the excitement produced by the gold-discoveries, and in 1853 he established a stock and station business with Messrs. Row and Kirk as partners, and bought stations in the Riverina; but deciding after four years to confine himself to wool-broking, he steadily developed that business until in 1881, by amalgamation with another firm, he was able to found the house of R. Goldsbrough & Co. with a capital of three millions. He died on 8 April 1886; after his death the firm, whose Sydney trade had almost equalled its Melbourne success, absorbed the famous firm of Mort & Co. and eventually became, as Goldsbrough, Mort & Co., one of the greatest wool businesses in Australia. While taking no part in public life, Goldsbrough by his enterprise combined with sound judgment benefited the pastoral industry of Australia as much as his own fortunes.

Golf. This game was played in Victoria as far back as 1847, but no details of the play are extant. The earliest games recorded in Sydney were played in 1855 on links laid out between Homebush and Concord (two western suburbs of Sydney) somewhere near the existing Concord links. John Dunsmore, a Sydney solicitor, is credited with having brought clubs and gutty balls from St. Andrews to introduce the game in New South Wales, and some of these sticks and balls are in the possession of the Australian Golf Club at its Kensington headquarters. Nothing came of this first enterprise, and golf was forgotten in Australia until

in the winter of 1882 C. E. Riddell formed a club with links in Moore Park, Sydney. This, the Australian Golf Club, flourished until Riddell went to England in 1889, and held contests for a cup, named the Cadogan cup after its donor. In September 1895 a meeting convened by J. W. Fletcher and G. S. Yuill resuscitated the club and renewed the cup contests. The Australian Club's links have been in Moore Park (1882-9), Queen's Park (1895-9), at Botany (1899-1905) and at Kensington. In 1893 a second club, now the Royal Sydney Golf Club, was formed by Gerald Campbell and Irving Kent; its links have been at Yaralla near Concord (1893-4), at North Bondi (1894-7), and at Rose Bay.

In Melbourne the first club formed was the Melbourne Golf Club (now 'Royal') in 1891, with links at Albert Park and Caulfield (1891-7), Fisherman's Bend (1897-8) and Sandringham: up to 1897 the Australian championship was decided on this club's links. In South Australia a club was formed in 1870, playing on the East Park lands, but died in 1876. In 1892 a new club, the Adelaide Golf Club, was founded, with links at Peterhead near Largs Bay (since abandoned) and on the North Adelaide Park lands.

Golf is now played in all the Australian States, each of which has its own association controlling State championships and sending delegates to an Australian union; this body regulates the national open, and amateur events, and has a representative on the Rules of Golf Committee of St. Andrews. The season lasts from March to October, and the national championship meeting is held annually in August or September in Melbourne, Sydney, and Adelaide in rotation. The game is played also throughout the summer, when courses in the tourist districts, both mountain and seaside, are well patronized. The metropolitan courses, on which the championships are played, are generally well designed. The principal clubs are the Royal Melbourne and Metropolitan (Melbourne), Royal Sydney and Australian (Sydney), and Royal Adelaide (at Seaton, near Adelaide). The winners of the Australian Open and Amateur Championships are:—

(a.) = amateurs.

The most notable Australian-born golfer who has participated in the British open championship is J. H. Kirkwood; he has recently secured a good professional appointment in America. Australians have contributed several books to the literature of golf, notably D. G. Soutar's *The Australian Golfer* (1906) and F. S. Shenstone's *Golf Rules and Decisions* (1924); and periodicals devoted to the game are published in Sydney and Melbourne. The growth of club membership and establishment of new courses have increased rapidly since the war ended.

T.T.

Gompholobium, a genus of the family Leguminosae, consisting of shrubs, with red or yellow flowers, endemic in Australia. The pod is oval to globular, inflated and slightly oblique. *G. grandiflorum* and *G. latifolium* are handsome shrubs with large, pale yellow flowers and tripartite leaves. *G. uncinatum,* a low spreading heath-like shrub, producing a profusion of attractive, brick-red flowers, is reputed to be injurious to stock. *Gompholobium* species are difficult subjects for cultivation.

Goodenia, a genus of the family Goodeniaceae, comprising 112 species of herbs or undershrubs endemic and widely distributed in Australia. The flowers are yellow, white or blue; calyx-tube 5-lobed and blended with the corolla-tube; the latter occasionally forms a spur at the base of the calyx, slit on the upper side, but in rare cases all the lobes are equal and spreading; stamens free; covering of the stigma cup-shaped; fruit a capsule, opening in two valves; seeds usually flat, with a thick border or membranous wing; leaves alternate, simple or incised, frequently in basal rosettes. *G. ovata,* a straggling undershrub with a slightly aromatic odour, is usually found in moist, shady situations. Its leaves are glossy, and exude a considerable quantity of resin. *G. stelligera* and *G. paniculata* are swamp-dwellers; the latter can survive a lengthy inundation. *G. decurrens,* with relatively large bright yellow flowers, grows in masses on the verge of dripping rocks in shady gullies. *G. barbata,* so named from the bristle-like hairs in the corolla-tube, has purplish wings attached to its corolla-lobes. Many species grow on the dry western plains.

Goodeniaceae, a family of almost exclusively indigenous plants, chiefly herbs, rarely undershrubs, with striking white, yellow, or blue flowers. It comprises 294 species, which are widely diffused over the continent. The calyx-tube is surmounted by 5 persistent lobes, small, united in a ring, or obsolete; corolla irregular, 5-lobed, their margins expanding into wings as the flower opens; stamens 5, alternating with the corolla-lobes; style simple, with a cup-shaped dilatation at the top enclosing the stigma; fruit a nut, drupe, or capsule opening in two or four valves. A feature of this family is the peculiar arrangement for the fertilization of the flowers. The female organ is covered by the cup-shaped dilatation of the style until it is ready to receive the pollen; brush-like hairs are so placed as to be ready to brush the pollen from the anthers on to the stigma when ripe; and the combination forms a complete apparatus for successful pollination. The genus *Brunonia* is limited to a single widespread but endemic species, *B. australis*—a silky-haired, perennial herb with a tuft of basal leaves, whose small flowers are crowded in a dense head at the top of a long flower-stalk. *Leschenaultia* is a western genus of herbs

or shrubs, the flowers of which are usually a brilliant blue, rarely white, red, yellow, or greenish. A sight of *Leschenaultia* country in

Leschenaultia splendens.

spring is a memorable recollection. *L. biloba* has a profusion of sky-blue flowers. *Calogyne* is a small genus with one representative in China. See DAMPIERA, GOODENIA, SCAEVOLA, SELLIERA, VELLEIA.

Goodenough, JAMES GRAHAM (1830-1875), born near Guildford in Surrey on 3 December 1830 and educated at Westminster school, in 1844 entered the navy (lieutenant, 1851; commander, 1858; captain, 1862) and saw service in the Pacific and Atlantic. In 1854-5 he served in the Baltic during the Crimean war, and from 1856 to 1861 was on the China station, taking an active part in several engagements of the Chinese war. By this time he had made his reputation as a scientific gunnery officer, and during the American civil war he was employed in watching gunnery developments in the northern States. After a period of service in the Mediterranean he was in 1871 placed on the admiralty committee on warship design, and a little later given experience as naval attaché in several European embassies. In May 1873 he was sent into the Pacific to command on the Australian station, with the rank of commodore—the station was not yet important enough to have an admiral—and found himself at once occupied with island affairs: he had to report on the expediency of annexing the Fiji group, and took Sir Hercules Robinson to complete the annexation and Sir A. Gordon to assume the governorship. In 1875 he visited the New Hebrides to promote friendly relations with the natives, and after success there proceeded to the Santa Cruz group with the same object; but on 12 August he was treacherously wounded with a poisoned arrow which produced tetanus, and died at sea on the 20th. He and two sailors who were wounded at the same time were buried in the burial-ground of St. Thomas's, North Sydney. (C.M.G., 1875; C.B., posthumous, 1879.)

Goold, JAMES ALIPIUS (1812-1886), born at Cork on 4 November 1812, educated there, admitted in 1830 to the order of St. Augustine, and ordained priest in 1835, met Dr. Ullathorne in Rome in 1837 and was induced by him to join the Australian mission. On his arrival in Sydney (on 24 February 1838) Dr. Polding made him assistant to Father McEncroe, and later on sent him to Campbelltown to succeed Father Therry. In July 1847 he was appointed to the new bishopric of Melbourne, consecrated on 6 August 1848, and installed on 8 October. In 1850 he laid the foundation-stone of St. Patrick's cathedral. For nearly 40 years he administered his diocese with skill and enthusiasm, procuring in 1874 the creation of two new dioceses—Ballarat and Sandhurst—and the elevation of Melbourne to an archbishopric. He took a very active interest in the education question as affected by local politics, and it was largely his influence that defeated Higinbotham's education bill of 1867 and ousted Berry at the elections of February 1880. In 1883 his life was attempted by his former solicitor. He died on 11 June 1886. E.M.O'B.

Gordon, ADAM LINDSAY (1833-1870), son of a military officer who had served in India and was afterwards professor of oriental languages at Cheltenham College, was born at Fayal in the Azores on 19 October 1833, and educated at Cheltenham, Worcester, and the royal military academy, Woolwich, also keeping a few terms at Merton College, Oxford. At none of these places was he a satisfactory student, and his exploits as a boxer and steeplechase rider so irritated his family that on 7 August 1853 he was sent off to Australia, armed with introductions to high society in Adelaide. He reached Adelaide on 14 November, and by the 23rd had enlisted in the mounted police and departed for his station, Mount Gambier. Two years later he resigned from the force and became a horse-breaker, leading a rather nomadic and lonely life in the Mount Gambier district, but establishing a valuable friendship with Julian Tenison Woods. In 1862 he married, and soon afterwards settled at Dingley Dell, half a mile from Cape Northumberland. In 1864 his first published verse appeared anonymously at Mount Gambier: it was a ballad entitled *The Feud*, written round six engravings of paintings by Noel Paton (originally made to illustrate that old ballad 'The Dowie Dens of Yarrow') which had been issued by the Royal Association for Promotion of the Fine Arts in Scotland. In 1864, too, he inherited £7000 from his mother, and was asked to stand in the anti-squatter interest for the electorate of Victoria in the south-eastern district of South Australia. In March 1865 he was elected, defeating the then attorney-general and bringing about the downfall of the Blyth ministry. In the house, however, he was not a success: his speeches were long, wandering, and full of unfamiliar classical

allusions, so that the *Telegraph* said:—'Lempriere has not been so hard-worked in this hemisphere for many a day as Mr. Gordon worked it on Tuesday.'

The two following years were probably the happiest of Gordon's life. He had a good income and a good position; he could indulge to the full in his favourite sport—horse-racing—and did so, winning the Adelaide Grand National on Cadger and the Ballarat Steeplechase on Ballarat; and, a demand arising for his manly, cheery doggerel (by no means all doggerel), *Bell's Life in Victoria* published in 1865-7 many racing pieces and 'Ye Wearie Wayfarer,' which contains most of the aphorisms that nowadays keep his memory green. At the end of 1866, however, he found his investments unsound and his career in parliament merely wearisome; he resigned his seat, and, after a short struggle to keep the South Australian home going on the proceeds of free-lance verse, migrated to Ballarat to take over the livery stables attached to Craig's hotel. About this time he published (at his own expense) his first important book of verse—*Sea Spray and Smoke Drift*—in Melbourne; but out of 500 copies printed he sold barely a hundred, and his next volume—*Ashtaroth*—was stillborn. He worked hard at the stables, and made himself popular as secretary of the local hunt club and in the local squadron of light horse; but he was no business man, and the partner he chose was less capable than himself. The firm was fast approaching insolvency when at the end of September 1868 he received from England a few small legacies and the news that he was the nearest male heir to the Scottish estate of Esslemont; also—and this pleased him much more—he created a record at Flemington on 10 October 1868, by winning three steeplechases in one afternoon, two of them on his own horses. Moreover in Marcus Clarke's newly founded *Colonial Monthly* he was hailed as the leading poetical genius of Australia.

On 1 October he had sold the stables, and began to depend on his riding for a living, winning many races during the following Christmas season, and bringing his family to Melbourne in the winter of 1869. Here he found for the first time since the Tenison Woods episode an intellectual companionship which might at an earlier date have inspired him to sustained and serious work. There was a ready market for his best verse in the *Colonial Monthly* and the *Australasian*; there was intimacy with Marcus Clarke and George Gordon McCrae and the Yorick club in general—Kendall was added later; there was a healthy life, full of swimming and riding. But at Ballarat he had been heavily thrown from a horse and had suffered injury to the skull, and a form of melancholia (the tendency to which he inherited from his mother) took hold on him. In March 1870 this tendency was aggravated by his being twice thrown in one race, a disaster which involved internal injuries as well as additional damage to the skull. Further, his attempts to secure the Esslemont estate failed utterly. He had at first neglected this matter, having no male heir to whom the estate might descend; but, when in January 1870 his claim was declared sound by an Edinburgh lawyer, he raised what cash he could and determined to prosecute it with vigour, incurring further debt on the strength of the income he expected to gain from it. In June the whole edifice collapsed, as it was discovered that a recent judicial decision put his case out of court. His new book of verse—*Bush Ballads and Galloping Rhymes*—seemed likely to involve him in more debt. On 23 June it was ready for publication, and he heard from the publishers what his liability was. This seems to have been the last blow. He met Marcus Clarke, full of congratulations; he spent two hours with Kendall, also eulogistic and comforting; but neither of them could dispel the fatal melancholia. Early the next morning he went out into the bush at Picnic Point on Port Phillip, and shot himself.

This tragic ending to a life of disappointments has somehow placed Gordon on a pedestal to which his actual literary work scarcely entitles him. In spite of Kendall's eulogy, he was never Australian, nor was his work; but he loved, and sang, life in the open and the virtues that naturally accompany it; and the manliness of his thought set to the lilt of his verse fascinated the young Australian spirit. To that extent—but to that extent only—he may be called, as Marcus Clarke calls him, the inaugurator of 'a national school of Australian poetry.' See LITERATURE.

Gore, WILLIAM, was born in England, but nothing else is known of his life until on 1 August 1805 he was appointed provost-marshal of New South Wales on the recommendation of the Earl of Harrington, then a general on the staff of the London district. The office was at the time not one of great importance; its previous holders had been a midshipman from the *Sirius*, a sergeant in the marines, and an acting-purser of H.M.S. *Buffalo*, and the salary attached to it was but five shillings a day; but King in 1806 described the provost-marshal as 'the ministerial officer of the executive authority and the courts of judicature,' his duties as comparable to those of a sheriff in England, and his position as one 'of great responsibility and trust in the present extended state of the Territory and its dependencies.' Gore left England with Bligh in the *Lady Sinclair*, and took occasion during the voyage to cultivate the new governor's friendship, so that after his arrival (on 6 August 1806) he was identified by the discontented settlers with Bligh's unpopular measures, and was one of the first to be imprisoned and tried by Johnston and his fellow-mutineers in 1808; indeed, in the previous year (1807) he had been the victim of false charges of theft and illegal uttering, and Johnston in his account of the mutiny described him as 'abandoned and unprincipled.' The mutineers imprisoned him for two months, tried him on a charge of perjury (to which he refused to plead, challenging their jurisdiction) and sentenced him to seven years' transportation to Newcastle; but on the arrival of Macquarie he was set free and sent to England as a witness on Bligh's behalf, Johnston also demanding his presence as one of the principal agents of Bligh's 'tyranny.' In May 1812 he returned to New South Wales and resumed office, but in July 1814 was thrown out of work by the action of Jeffery Hart Bent (q.v.) in suspending all legal proceedings in the civil courts. It would seem that the provost-marshal had a right to certain fees or perquisites while actively engaged in his duties, for Gore in 1817 complained to the colonial office that for 7½ years of his term (1808-12 and 1814-7) he had received nothing but his bare pay. By this time, however, he had fallen into disrepute, his salary was assigned to creditors, and he himself, after attempts to evade arrest, had been

committed to a debtors' prison, had escaped therefrom, on 6 March 1819 was on the recommendation of the judges suspended from office, and in 1820 was removed from it. Retiring to his home on Gore Hill, he lapsed into drunken habits, and on 19 January 1824 was convicted of having shot at and wounded a soldier who was trespassing on his property; Brisbane, however, pardoned him, and he lived in obscurity until his death. This did not take place until 1845, probably to the great regret of Lord Palmerston, who in 1823 enquired anxiously whether Gore had yet 'paid the Debt of Nature,' as he was 'a last Life in an old Irish Lease.' Brisbane, who lacked a sense of humour, took the enquiry for a mark of Palmerston's interest in Gore, and it was partly because of this that he granted the pardon.

Gosse, WILLIAM CHRISTIE (1842-1881), born in 1842 at Hoddesdon in Hertfordshire, was in 1850 brought by his father to South Australia, educated privately in Adelaide, and at the age of 17 enrolled as a cadet in the surveyor-general's department and sent to the far north of the colony. His early experience of this region was remembered when in 1873 the South Australian government, stimulated thereto by the explorations of John Forrest and Ernest Giles in the area west of the overland telegraph line, decided to despatch an expedition into the unknown lands west of the Macdonnell Ranges. Gosse, given command of the expedition, started from Alice Springs on 23 April 1873 and managed to reach the Townsend Range, about 100 miles within the Western Australian border, but was then forced to turn back; a little later in the same year Giles was blocked almost at the same place. As a reward for his work Gosse in 1875 was made deputy surveyor-general, but his health failed, and he died prematurely on 12 August 1881.

Goulburn, HENRY (1784-1856), born in London on 19 March 1784 and educated at Trinity College, Cambridge (B.A., 1805; M.A., 1808), entered politics in 1807 and in 1810 was made under-secretary for the home department. In 1812 he was transferred to the department of war and the colonies, succeeding Sir Robert Peel there as under-secretary and holding the post (under Bathurst as secretary) until December 1821. He was afterwards chief secretary for Ireland (1821-7), chancellor of the exchequer (1828-30 and 1841-6), and home secretary (1834-5); from 1831 to 1856 he represented the university of Cambridge in parliament, and Oxford made him a D.C.L. in 1834. Although the policy of the colonial office in regard to New South Wales was nominally Bathurst's, Goulburn's intimate knowledge of its affairs, stimulated by his long and elaborate correspondence with Macquarie, made him an important influence on Australian development. The Goulburn River in New South Wales and the town of Goulburn in the same colony were named after him. He died at Dorking in Surrey on 12 January 1856. (P.C., 1821.)—His younger brother FREDERICK GOULBURN (1788-1837), joined the army in 1805 (cornet, 1805; lieutenant, 1806; captain, 1810; major, 1816; lieutenant-colonel, 1836) was present at Waterloo, and on 30 June 1820 was appointed colonial secretary of New South Wales. Here he fell foul of the judge-advocate, and of the governor, by claiming privileges and an independent discretion that were not actually justified by his position; in December 1824, therefore, he was recalled. Although his conduct in the colony had been condemned by Bathurst, he had influence enough in England to secure on his return an appointment as under-secretary for Ireland, and the offer in 1829 of a colonial governorship; this he refused, preferring to retire into private life. He died at Southgate in May 1837. The Goulburn River in Victoria was named after him.

Gould, JOHN (1804-1881), son of a working gardener, was born at Lyme Regis in Dorset, England, on 14 September 1804. From early youth he was interested in wild bird life and skilful in taxidermy. At 14 he worked under his father, who had just become a foreman gardener at Windsor Castle. In 1827 he was appointed taxidermist to the Zoological Society of London; and three years later, receiving from the Himalayas a collection of bird-skins, produced his first volume of bird illustrations, the *Century of Himalayan Birds*—which he had to publish at his own expense. In 1837 he published a *Synopsis of the Birds of Australia* with 72 plates, and in 1838 went himself to Australia with strong recommendations from the colonial office. There he spent two years in collecting and in the instruction of subordinate collectors, and personally explored a great part of New South Wales, South Australia, and Tasmania. On his return to England in 1840 he commenced the publication of his great work on Australian birds in seven volumes, containing 601 plates. He was sadly hampered during the next few years by the loss of several of his Australian collectors. John Gilbert, who had accompanied him from England, and had made collections in Western Australia and at Port Essington and Moreton Bay, was killed by natives during the Leichhardt expedition of 1844; Johnston Drummond met the same fate in Western Australia, and F. Strange in the Wide Bay district of Queensland in 1846; and a collector obtained for him by Sir John Franklin was accidentally shot on an island in Bass Strait. Sir John, then governor of Tasmania, took great interest in Gould's researches, and his youngest son—Charles Gould, afterwards Tasmanian government geologist—was born at government house, Hobart. The collection of Australian birds—1800 specimens—was offered for £1000 to the British Museum (Gould's out-of-pocket expenses had amounted to double that sum), but was rejected: it was then bought by Dr. Wilson of Philadelphia, and by him presented to the Philadelphian Academy of Natural Science. The rejection by the British Museum—which at first sight would seem inexplicable—has been cleared up by a discovery of G. M. Mathews (see his *Birds of Australia*, ix. 105-6) that many of Gould's type-specimens had already been either presented to the museum by Gould or bought by the trustees from him.

It was not only the birds of Australia that interested him. In 1844 he brought out a *Study of the Macropodidae* (*Kangaroos*) with 45 plates, and between 1845 and 1863 produced three volumes on *The Mammals of Australia* with 182 plates. The seventh volume of the *Birds of Australia* appeared in 1848, and in 1851 he began to issue in parts a supplementary volume with 81 plates, the last part of which appeared in 1869. The magnificent plates of this series, in which a large proportion of the birds are represented life-size and with backgrounds of characteristic Australian vegetation (sketched by the author and his wife in Australia), make it one of the most important works on birds ever produced.

Meanwhile he had issued in 1865 a two-volume *Handbook to the Birds of Australia*, in which about 660 species are described; of these a considerable number are now regarded as merely geographical races or sub-species, but in the succeeding 50 years only about 100 more have been discovered, and many of these are rare or casual visitors from oversea. These three books —the *Synopsis* of 1837-8, the *Birds* of 1840-69, and the *Handbook* of 1865—must be carefully distinguished. His last contribution to Australian zoology was *The Birds of New Guinea and the Adjacent Papuan Islands* (141 plates), published between 1875 and 1880, and completed after his death by R. B. Sharpe of the British museum.

Gould's work was by no means confined to Australia. His total output was 41 folio volumes, illustrated by 2999 plates, as well as 300 memoirs and papers for various scientific journals. The more important volumes, apart from those already mentioned, are *Birds of Europe* (449 plates, 1832-7), *Monograph of the Trochilidae or Humming-Birds* (360 plates, 1849-61), *The Birds of Asia* (497 plates, 1860-80), and *The Birds of Great Britain* (367 plates, 1862-73). In 1843 he was elected a fellow of the Royal Society. He died in London on 3 February 1881.

Gould was a man of simple, kindly nature, with a passion for his work. He loved to be called 'The Bird Man,' and that is his best epitaph. But his work cannot be dismissed so lightly; apart from its mere volume—which, as the above account has shown, was very great —his study of so many life-histories of birds, and his discovery of the nesting habits of the megapodes (see MOUND-BIRDS) and the even more remarkable structures of the bower-birds (q.v.), rank it among the really great contributions to our knowledge of nature. His wife, a Miss Coxen, whom he married in 1829 and lost in 1841, was an excellent assistant, and while she lived undertook the transference of his sketches to the lithographic stone for printing, besides (as has been already mentioned) helping in the preparation of the sketches themselves.

6 July 1917	9 February 1920	Newdegate, Sir Francis Alexander Newdigate, K.C.M.G. (From 9 February to 16 April the State was administered by Sir Herbert Nicholls.)
16 April 1920	27 January 1922	Allardyce, Sir William Lamond, K.C.M.G. (From 28 January 1922 to 22 December 1924 the State was administered by Sir Herbert Nicholls, and during his illness by Mr. Justice Ewing.)
23 December 1924		O'Grady, Captain Sir James, K.C.M.G., O.B.E.

Goyder, George Woodroffe (1826-1898), born in Liverpool on 24 June 1826, in 1848 migrated to Australia; reaching Adelaide in 1851, he entered the public service, and in 1854 acted as deputy surveyor-general. In 1857 he penetrated the area north-east of Beltana, which was then believed to be saline and waterless, and found it timbered and traversed by deep creeks; Lake Blanche, which Sturt had found 'salt and brine,' was when Goyder reached it full of fresh water and apparently 30 miles or more long. Freeling, the surveyor-general, following his tracks six months later, could find no fresh water at all and was pessimistic about the possibility of expansion in that direction; but the view of his official heads may be judged by the fact that in January 1858 Goyder was definitely made deputy surveyor-general, and in 1860 succeeded Freeling as head of the department. From that time on he did little exploring work, though he actively supported every attempt to extend the knowledge of South Australian territory. His most important expedition was undertaken in 1868-9, when he was sent to the Northern Territory to survey areas for intending leaseholders. The officials previously sent there had attempted to locate a site for the chief settlement either on the estuary of the Adelaide or on that of the Victoria: Goyder, anchoring in Port Darwin on 5 February 1869, soon discovered a suitable site, and by the end of August had laid out the township of Palmerston and (in spite of bitter resistance from the aborigines, whom he vainly tried to conciliate) had surveyed about 700,000 acres for farming land. The other measure with which his name is closely connected is the first delineation of a boundary for wheat-growing, based on an average 14-inch rainfall. This line, known as 'Goyder's,' runs from a little north of Pinnaroo in a curve past Eudunda and Kooringa to Terowie, then between Yongala and Petersburg, then north-west to Mount Remarkable and south to Moonta; it has been of late years extended by improved methods of dry-farming, but on the whole is still substantially correct, wheat being profitably grown between it and the sea but not to any great extent beyond it. In 1880 Goyder was sent by the government to England to procure machinery for putting down deep bores in search of water, a scheme which he had for many years strenuously advocated. He left the service in December 1893, and in 1898 died at Aldgate in South Australia. (C.M.G., 1889.)

Grainger, Percy Aldridge, born at Brighton near Melbourne on 8 July 1882 and trained for a musical career by Louis Pabst in Melbourne, James Kwast in Frankfort, and Busoni in Berlin, gave concerts in Australia at the age of 12 and in Berlin and London at 17, and then toured Australasia with Ada Crossley (1903), Scandinavia with Herman Sandby (1904), and Britain with Adelina Patti (1905). In 1906-7 he visited Grieg in Norway and, becoming an intimate friend, has since been one of the Norwegian composer's best interpreters. From 1912 onwards he devoted himself to composition, employing folk-songs of various nationalities with great skill. Since 1915 he has lived mainly in the United States.

Grant, James (1772?-1833), was at the end of 1799—being at that time a lieutenant in the navy—appointed by the admiralty to command the *Lady Nelson* on her voyage to Australia. His choice was due partly to the recommendation of Sir Joseph Banks, partly to the fact that he was a close friend of Captain Schanck, who had designed the vessel with three centre-boards specially for survey work in shallow waters; under Grant, it was thought, the experiment would have a fair trial. The admiralty, knowing that Grant was no surveyor, had intended that on his arrival in Port Jackson he should be transferred to the *Supply*, and (probably) that Flinders should take over the survey work; but when he did arrive (on 16 December 1800) the *Supply* had been condemned as unfit for sea, Flinders was gone, and King had no one fit to conduct the coastal explorations for which the *Lady Nelson* had been sent out. He therefore offered Grant a continuance of his command, particularly praising his skill and perseverance in bringing the *Lady Nelson* through Bass Strait. An account of the subsequent explorations (December 1800 to July 1801) will be found under Exploration by Sea. To supply Grant's deficiencies as a surveyor Francis Barrallier (q.v.) was sent with him; but the arrangement was not comfortable for the naval officer, and on 31 August 1801 he straightforwardly admitted his incapacity for the work and asked leave to return to Europe, 'where I may be enabled to render myself more serviceable to my country.' King with equal straightforwardness, when granting the leave, regretted its cause; 'I should have been glad,' he wrote, 'if your ability as a surveyor . . . . was any ways equal to your ability as an Officer and a Seaman.' Leaving Port Jackson on 9 November 1801, Grant made his way to England—losing on the way some important despatches entrusted to him by King—served in

the North Sea, was made commander on 12 January 1805 for gallantry in action while in command of the *Hawke* cutter, and was granted a pension of £150 in 1806 on account of wounds received in action, but continued in the service and in later years commanded the sloops *Raven* and *Thracian*. He died at St. Servan (near St. Malo in France) on 11 November 1833. In 1803 he published a *Narrative* of the explorations of 1800-01, with a note on the origin and advantages of centre-boards.

Grant, JAMES MACPHERSON (1822-1885), born at Alvie in Scotland in 1822 and educated at Kingdenie, was in 1836 brought by his parents to Sydney and articled to a firm of solicitors. In 1844 he visited New Zealand and as a volunteer saw something of the war against Hone Heke. On his return to Sydney he was admitted a solicitor and practised for three years, then visiting San Francisco for his health's sake; he came back to try his luck on the Victorian goldfields, did well, and in 1854 commenced practice in Melbourne, becoming prominent by his successful defence (without fee) of the Eureka Stockade rioters early in 1855. This brought him into politics, and in November of that year the miners of Bendigo returned him as their representative to the council, sending him back in 1856 to the new assembly. In 1859 he was returned for Avoca, and retained that seat till 1883. On 20 February 1861 he began a ministerial career that lasted (with the natural interludes of life in opposition) for more than 20 years: he was commissioner of works in the Heales ministry (1861), commissioner of railways and afterwards president of the board of lands and works in two McCulloch ministries (1863-8 and 1868-9), president of the same board in the Duffy ministry (1871-2), minister of justice in two Berry ministries (1875 and 1877-80), and chief secretary and minister of public instruction in the O'Loghlen ministry of 1881-3. He was, that is, a politician of importance, for whom a post must be found in any ministry formed from his party. But his real interests were centred on land legislation; anxious to settle people on the land, he helped Heales to strain the 'occupation license' clauses of the Nicholson land act so as to place nearly 2000 persons on land which they could not otherwise have obtained for cultivation, and in 1865 passed an act—based on the principle that *bona fide* settlement should precede alienation—which increased settlement by 3½ million acres. An amending bill devised by him in 1868 was adopted by the ministry that succeeded McCulloch's, and became the land act of 1869, under which nearly 11 million acres were settled in nine years. The actually cultivated area grew under these two acts from 470,000 to 1,400,000 acres. He died at Melbourne on 1 April 1885.

Grass-bird. See WARBLERS.

Grasses. This article deals with (*a*) grasses native to Australia, (*b*) introduced grasses.

A. The *native grasses,* of which there is a great variety, possess remarkable nutritive and (in many cases) drought-resisting qualities. In the wheat-growing districts they have been largely displaced by introduced grasses, but in the pastoral areas excellent results have been obtained from them by judicious stocking. The germination of certain kinds (e.g. *Panicum* and *Andropogon*) has been proved to be very high. The chief dangers that threaten them are rabbits, overstocking—which tends to exterminate the better grasses and allow only the inferior to survive—and the lack of a proper subdivision of paddocks, whereby the grass is persistently eaten down and given no chance to shed its ripened seed.

There are over 200 species of native grasses, many of which have little economic value. The following are among the most important:—*Agropyrum scabrum* (Wheat-grass) has a wide range in pastures, and provides good feed in the early spring. *Agrostis* (a genus including the Bent and Snow grasses) occurs on the southern Alps, and is particularly valuable for sheep. Of the blue grasses (*Andropogon*) the most important is *A. sericeus* (Queensland Blue grass), found through the greater part of Queensland and the north-west of New South Wales; it is an excellent grass for fattening, and has palatable qualities. *A. intermedius* (Rare Blue grass) and *A. affinis* are common in New England; both respond well to cultivation. *A. bombycinus* and *A. erianthoides* are found in the far western districts of New South Wales and Queensland, and are strongly drought-resistant. Of the kangaroo-grasses (*Anthistiria* or *Themeda*) the most important are *A. ciliata* (*T. Forskallii*), the common Kangaroo-grass, and *A. avenacea*, the Wild-oat grass. Kangaroo-grass formerly occupied a wide area throughout the greater part of Australia, but soon succumbed to heavy grazing, and is now only found in abundance in protected areas. It is a valuable cattle-grass. Wild-oat grass is still fairly plentiful on plain country in New South Wales and Queensland, and is even better for cattle than kangaroo-grass.

Wire-grasses, also called three-awned spear-grasses (*Aristida*), are common in every State except Queensland, and are found chiefly on poor country. All except *A. Behriana* are very harsh, and little eaten by stock. The famous Mitchell grasses—*Astrebla elymoides* (Hoop Mitchell), *A. pectinata* (Curly Mitchell), and *A. triticoides* (Bull Mitchell)—have fattened more stock in Queensland than any other grass. They are highly nutritive, very quick-growing, and palatable even to maturity. They seem, however, to thrive only in the warmer northern parts of Australia. *Cenchrus tribuloides* (Burr-grass) is a rather coarse grass which produces good feed for stock in partly cleared scrub-lands in eastern Australia.

Of the star or windmill grasses the most important are *Chloris acicularis* (Umbrella-grass) found in the interior of Queensland, New South Wales, South Australia, and Western Australia; *C. barbata,* confined to Queensland and central Australia (sometimes called Australian Rhodes grass); *C. divaricata,* found in Queensland, New South Wales, and the Northern Territory; *C. truncata,* found throughout Australia; and *C. ventricosa* (Tall Star-grass) found in Queensland and New South Wales. All are valuable sheep-grasses, commencing growth in early spring and lasting well into the autumn.

Cynodon dactylon (Couch, Bermuda-grass, Doub-grass) is perhaps the most cosmopolitan grass in the world, as common in Australia as in India or America. It follows the plough everywhere, and forms a great carpet on river-flats in the warm months of the year. All stock eat it greedily, and fatten on it. *C. incompletus* (Blue Couch) is very like ordinary couch-grass, but is poisonous; fortunately it is not abundant (see NOXIOUS PLANTS).

The wallaby, white-top, or fluffy-top grasses (*Danthonia*) are the most persistent of all our

native grasses, abundant in every State except Queensland. In the wheat-growing districts they flourish on hill-sides, and are particularly valuable for sheep. They are the best winter native grasses Australia possesses, the largest and best species being *D. semiannularis, D. pilosa, D. varia, D. seminuda, D. Duttoniana,* and *D. caespitosa.*

Plume-grasses (*Dichelachne*) are common on the coasts and tablelands, but are not particularly valuable for pasture. Of *Diplachne* the commonest species is *D. loliiformis,* abundant on the black soils in Queensland and New South Wales; all the species are very palatable. A splendid cattle-grass of the genus *Ehrharta* occurs in Western Australia, but was probably introduced from South Africa.

The principal species of *Eleusine* are *E. aegyptiaca* (Button-grass) and *E. indica* (Crowfoot-grass). Button-grass is common in New South Wales, Queensland, and central and northern Australia. It grows quickly after summer thunderstorms, and is a good palatable grass for sheep. The less valuable crowfoot-grass is common in eastern Australia.

Of *Eragrostis* there are two groups—the wide-leaved species, commonly called love-grasses, of the coast and tablelands, and the usually narrow-leaved drought-resistant species of the interior, sometimes called never-fail or everlasting grasses. The latter are often provided with root-sheathing cases of sand, and with a dense coating of hairs at the base of the stem to prevent rapid evaporation. All are valuable sheep and cattle grasses, mostly confined to Queensland, New South Wales, and Victoria. *E. leptostachya* (Paddock Love-grass) and *E. Brownii* (Brown's Love-grass) are valuable for dairying.

Eriachne contains mostly northern Australian grasses, valuable for big stock. *Eriochloa* contains early spring grasses, palatable and nutritious, which are fairly common in New South Wales, Queensland, and the Northern Territory, and do remarkably well under irrigation. The water-grasses (*Glyceria*) are good cattle-grasses, found in marshy situations of the interior. *Hemarthria compressa* is a common coastal grass, found in sheltered situations throughout Australia; it is of little grazing value.

Imperata arundinacea (Blady grass) is widely spread in the southern hemisphere. It occurs abundantly after bush fires in the coastal districts, is very harsh, and is said to be good material for making paper. The species of *Isachne* are palatable, but not very abundant; they occur in the eastern States. *Iseilema (Anthistiria) membranacea* (Flinders, Barcoo, or Landsborough grass) is one of the most valued grasses in Queensland and northern New South Wales, and in popularity ranks next to the Mitchell grasses, with which it is often associated.

Of the mulga-grasses (*Neurachne*) the two most important are *N. alopecuroides,* found from New South Wales to Western Australia, and *N. Mitchelliana,* found in western New South Wales and Queensland. The latter is a good summer grass, frequently seen in mulga country. *Oplismenus compositus* is a trailing grass, found in moist situations in eastern Australia. *Oryza sativa* (Rice) is now growing wild in the Northern Territory, and may do great things under cultivation.

The genus *Panicum* provides a number of vigorous summer grasses of great value, with drought-resisting and nutritious qualities. The following are specially important. *P. decompositum* (Native Millet) and *P. prolutum* (Coolah-grass), found in all the States except Tasmania, are highly responsive to cultivation; the latter is a rapid grower under dry conditions, and will stand heavy grazing, though rather harsh when in flower. *P. flavidum* (Warrego Summer-grass) and *P. distachyum* are palatable grasses, widely distributed in the interior; the seed of the former germinates readily, and thrives under cultivation. *P. colonum* (Swamp or Barn-yard-grass) and *P. crusgalli,* a native of the eastern States, are closely allied to the Japanese millet; the former is sometimes a weed in other crops, the latter may be distinguished by its 'awned' flowers. *P. divaricatissimum* (Spider or Umbrella-grass) is spread over the interior of New South Wales and Queensland, where its seed-heads are commonly seen piled up against fences. There are two varieties, hairy and smooth, of which the former is strongly drought-resistant. Less palatable than some panic grasses, they provide good feed during the hot months. *P. leucophaeum* (Cotton Panic-grass) is short-lived, but grows quickly after thunderstorms in the interior of all the States. *P. trachyrachis* (Coolabah-grass) is common in the elevated parts of northern Australia. Less palatable species are *P. effusum* and *P. gracile,* found in all the States except Tasmania; the former, common in upland regions, bears a large seed-head which detracts from its grazing quality; the latter is a variable grass, of which the inland form is rather harsh. *P. marginatum* and *P. parviflorum* are eastern scrub-land grasses of little value.

The species of *Pappophorum* (sometimes called black-heads, from the colour of the inflorescence) are common in all the States except Tasmania, but are rather harsh and unpalatable. *Paspalum distichum* (Water Couch or Swamp Couch-grass) is a very valuable grass, found in moist situations in all States except Tasmania. It is credited with being one of our best fattening and milk-producing grasses. *P. scrobiculatum* (Ditch Millet), found in the eastern States in moist situations, is suspected of possessing poisonous properties. *Pennisetum compressum* (Squirrel-tail-grass) is found in the eastern States on the coast and tablelands, sometimes crowding out all other grasses. Unfortunately it is very harsh and quite unpalatable, as is *Poa caespitosa* (Australian Poa or Tussock Poa), common throughout Australia on the coast and tablelands, and strongly drought-resistant. It grows well during the cold months of the year. On black basaltic soils tussocks of this grass may be seen untouched by sheep, while all other vegetation is eaten out. The variety *latifolia,* limited in abundance, is eaten by large stock. *P. lepida* is a fairly palatable grass, occurring in the interior of New South Wales and South Australia.

Pollinia (Erianthus) fulva (Brown-top or Sugar-grass) is a valuable endemic, found in all the States except Victoria and Tasmania; most pastoralists speak highly of it as drought-resistant and nutritious. It also thrives under cultivation but the seed does not germinate well. *Setaria glauca* (Pigeon-grass), closely allied to the Hungarian and Manchurian millets, is found throughout Australia, particularly in moist situations. Being a short-lived summer grass, it is eaten readily in the young stages, but is likely to become troublesome in cultivated crops. *Sorghum (Andropogon) halepense* (Johnson grass) is possibly not indigenous, but is now well established throughout Aus-

tralia. Its underground creeping rhizomes possess remarkable vitality, and it is one of the worst pests in cultivated crops—see NOXIOUS PLANTS. Inland, where cultivation is little carried out, it can be strongly recommended as a pasture grass. *S. plumosum* (Wild Sorghum), found in all the States, especially in the highlands, is harsh and unpalatable. *Spinifex* is dealt with separately. *Sporobolus indicus* (Parramatta grass) is found throughout Australia, mostly in the coastal districts; it is a tough, wiry grass that has been known to loosen the teeth of horses grazing on it. It often takes possession of buffalo and couch lawns. Closely related to it is *S. diander*, which is more succulent. *S. Lindleyi* (Pretty Sporobolus) is a short-lived summer species, found in all the States except Tasmania, generally inland; it is succulent and palatable, with a handsome inflorescence. *S. virginicus* grows well in saline situations.

The *Stipa* (corkscrew or spear) grasses are amongst the commonest in Australia, being found in every State except, perhaps, the Northern Territory. Most abundant in the interior, they often form an association with *Danthonia* grasses, crowding out other vegetation. Most are useful, in spite of their harsh character, for their drought-resistant qualities and because they provide early spring feed. The ripe seeds are troublesome, penetrating the skin, eyes, and jaws of grazing stock. The most important species are *S. aristiglumis* (Plains grass) which grows in a good season to a height of six or seven feet, fattens cattle very quickly and is abundant in the north-west of New South Wales; *S. flavescens*, common in the southern States; and *S. pubescens*, *S. scabra*, and *S. setacea*, found in *Danthonia* pastures in all the States except Queensland.

Tragus (*Lappago*) *racemosus* (Burr-grass), found in the interior in all the States except Tasmania, is short-lived and common on cultivated lands. It is palatable and nutritious. *Triraphis mollis*, found occasionally but not abundantly in the interior of all the States, is a good grass for both large and small stock.

B. The coastal and plateau regions of Australia are particularly adapted to the growth of certain *exotic* grasses, many of which have greatly improved our sheep and cattle pastures. The following are the most important:—*Agrostis alba*, var. *stolonifera* (Creeping Bent grass) is useful for lawns and golf links, or as a constituent of pastures in cool, moist situations. The fox-tail grasses (*Alopecurus*) are fine-leaved grasses, sometimes included in mixtures for cold districts. *Andropogon sorghum*, var. *sudanensis* (Sudan grass) was introduced in 1913, and is now very much in favour amongst farmers in the wheat and dairying districts. It is strongly drought-resistant and nutritious, producing an enormous amount of fodder in summer and autumn. It can be grown for hay, silage, or as pasture. Cases of poisoning from this grass have recently been recorded, but, on investigation, it has been found that such poisoning was due to sorghum-Sudan grass hybrids, the result of sowing impure seed. *Avena elatior* (Tall Oat-grass), a succulent grass, grown largely in New Zealand, is a valuable constituent of winter pastures.

Bromus inermis (Awnless or Hungarian Brome grass) is a perennial grass of excellent nutritive value, which appears more adapted to the highlands than to the coast. *Bromus unioloides* (Prairie or Rescue grass) is one of our best winter grasses, and generally included in rye-grass-cocksfoot mixtures. Being an annual, however, it soon disappears under heavy stocking. A promising perennial strain is now being developed.

Chloris Gayana (Rhodes grass) is very popular in Queensland, but in eastern New South Wales is outclassed by *Paspalum dilatatum*. More drought-resistant and succulent than *Paspalum* in its young stages, it will not carry as many stock as the latter in an ordinary season. *Cynosurus cristatus* (Crested Dog's-tail) is a good winter grass, often used in mixtures in Victoria and Tasmania. *Dactylis glomerata* (Cocksfoot or Orchard-grass) is one of the oldest and most reliable of all introduced grasses, and is particularly adapted to cold localities. Owing to its tussocky habit, it is generally mixed with perennial rye-grass. *Eragrostis abyssinica* (Teff grass) is an annual, which takes the place of millet in Queensland and the warmer areas of other States.

Of the fescue grasses (*Festuca*) the coarsest and most drought-resistant is *Festuca arundinacea* (Giant Fescue), which is a good cattle-grass; Hooker's fescue is a form of this grass. The fine-leaved fescue grasses, *F. ovina* (Sheep's Fescue), *F. rubra* (Red Fescue), and *F. duriuscula* (Chewing's Fescue), are often used as constituents of pastures in dry situations. *Holcus lanatus* (Yorkshire Fog) has a low nutritive value, and can only be recommended for marshy areas and poor soils where other grasses will not grow. *Lolium italicum* (Italian Rye-grass) is most important for the cooler localities. It is often sown with a winter cereal crop, and provides a great amount of overmath which can be utilized for pasture; it also makes excellent hay. Westernwolth's rye-grass is a superior variety of Italian rye-grass. *L. perenne* (Perennial Rye-grass) is one of the most widely known of all introduced grasses. It revels in cool, moist situations, and a pasture mixture of cocksfoot, rye-grass, and red clover is probably an ideally balanced ration. Perennial rye-grass will not endure much hot, dry weather. *L. subulatum* (Wimmera Rye-grass) has lately come into favour as a good winter and spring grass in the wheat-growing districts of Victoria.

Melines minutiflora (Molasses-grass), a South American plant, promises good results in Queensland and on the northern rivers of New South Wales. It has a distinct 'sticky' feel, due to the presence of a large amount of mucilage.

Oryzopsis miliacea (Little Millet) is adapted to very dry situations, but is slow-growing, and hence not popular with farmers. *Panicum maximum* (Guinea grass) is a palatable, nutritive grass, suitable for warm, moist localities, as also is *P. muticum* (Para grass), which spreads vigorously from its creeping stems.

Paspalum compressum (Carpet grass) is well adapted to poorer soils in moist situations. It does not spread as rapidly as *P. dilatatum*, but is more palatable and nutritive. *P. dilatatum*, the commonest introduced grass in Australia, on which alone thousands of dairy stock are kept in eastern New South Wales, is discussed under PASPALUM. *Pennisetum clandestinum* (Kikuyu grass) is an African grass of recent introduction. In summer it overruns the ground at a very rapid rate, and is most promising for the warmer parts of Australia. *P. purpureum* (Elephant-grass or Napier's Fodder) is another African introduction, which in the warm months of the year produces up to 70 tons of grass-feed per acre, and is suitable for any

locality where frosts are not severe. *Phalaris bulbosa* (Toowoomba Canary-grass) is the best winter grass yet introduced into New South Wales. Succulent and palatable, it will stand a good deal of stocking, and can be strongly recommended for agricultural districts throughout Australia. *P. canariensis* (Canary-grass), an annual, is suited to the same localities. *P. minor* (Wild Canary-grass) is spreading through the wheat-growing districts of New South Wales and Victoria, and is often found in association with *Hordeum murinum* (Barley-grass), but is much more valuable. *Phleum pratense* (Timothy grass) is mostly grown for hay; it does fairly well in the elevated parts of New South Wales and Victoria.

Poa aquatica (Water-grass) is adapted to cold localities, and is propagated by roots which run vigorously through the soil. *P. compressa* (Canadian Blue grass), a fine-leaved grass, does well in parts of Victoria. *P. pratensis* (Kentucky Blue grass) is an excellent constituent of pastures in the colder districts. Slowly established, it is then most persistent, providing excellent feed for sheep. *Setaria nigrirostris* (South African Pigeon-grass) is a perennial form of pigeon-grass which produces a large amount of summer feed. Buffalo-grass (*Stenotaphrum glabrum*) is the favourite grass for lawns on the coast, and in localities where the winters are not too severe. Before the advent of *Paspalum* it was used largely on the northern rivers of New South Wales; owing to its coarseness, however, it has now been discarded for this purpose. *Tricholoena rosea* (Natal Red-top) does very well in Queensland, but is not considered very palatable. It has a handsome inflorescence.

In the wheat-growing districts of most States certain introduced plants have completely displaced the native grasses. In good seasons this herbage, if conserved as silage, would give a larger amount of fodder than the product of the original pastures—probably ten tons per acre. Amongst them are the following:—*Medicago lacinеata, M. maculata,* and *M. minima* (Burr Trefoils); *Erodium cicutarium* and *E. moschatum* (Crowfoot-grasses), which form rosettes in *Danthonia* and *Stipa* pastures; *Trifolium glomeratum* and *T. tomentosum,* nutritious clovers abundant in the Riverina and Victoria; *Malva parviflora* (Marsh Mallow); *Carduus marianus* (Variegated Thistle) and *C. pycnocephalus* (Slender Thistle); *Hordeum murinum* (Barley-grass), the commonest of all introduced herbage, the ripe seeds of which are troublesome to stock; *Festuca bromoides* (Rat's-tail Fescue); *Lamarckia aurea, Bromus maximus, B. mollis,* and *B. racemosus.* E.B.

Grasshoppers and Locusts, insects of the order Orthoptera, comprising two distinct groups (*a*) the long-horned grasshoppers or Tettigoniidae (Locustidae of some authors, by a time-honoured misconception) and (*b*) the short-horned grasshoppers or Acridiidae. The Tettigoniidae are very abundant, nearly 200 Australian species being known. The huge and fierce King Cricket (*Anostosoma australasiae*) lives in holes in the ground, and in many respects resembles the Gryllidae (see CRICKETS). Many handsome species live in the dry western districts of New South Wales and Queensland; Plate xix, fig. 3, shows the rare and remarkable Crested Grasshopper (*Alectoria superba*). A handsome speckled grasshopper (*Ephippitytha 32-guttata*) is rather common in coastal districts. The Mountain Grasshopper (*Acridopeza reticulata*), the female of which has peculiarly crinkled, half-developed wings, and the remarkable Cave Grasshoppers of the genus *Pachyrhamma,* with their excessively long antennae, are interesting members of our fauna.

Some of the species are troublesome to orchardists, but many are carnivorous. The winged males makes a curious noise, usually after sunset, by rubbing parts of the wings together, each species making its own characteristic sound. Each female is provided with an ovipositor, in some species short and curved, in others thin, straight, and long. A Western Australian species of *Metaballus* is an orchard pest, and eats large holes in ripening fruit. The ovipositor of the female is as long as the rest of the body.

The short-horned grasshoppers (Acridiidae) are the most highly specialized of the Saltatoria, and include the true plague-locusts. More than 350 Australian species of this family have been described; but more still remain to be described, especially among the peculiar pigmy locusts (Tettiginae), of which several species are found in the inland districts. Many handsome members of this family are familiar members of our insect fauna; plate xix, fig. 4, shows the inland species *Stropis maculosa.* Other well-known genera are *Goniaea, Coryphistes, Hyalopteryx, Monistria,* and the peculiar *Acrida.* In the last-named genus the head is pointed, and the thickened antennae are held straight out in continuation of it. *Coryphistes ruricola,* a large species of a mottled grey colour, rests on the bark of trees where it is not easily seen.

The name 'locust' is also popularly, but erroneously, applied to the cicadas (q.v.). R.J.T.

In Europe, Asia, and Africa from time immemorial locusts have appeared in overwhelming numbers, and have devoured every green thing over wide areas. In the United States and Africa, especially, concerted efforts are now made to destroy the mature insects on a wholesale scale, to map out their egg-laying districts, and to destroy the eggs and newly-hatched young. Although their visitations have been less disastrous in Australia, yet great loss of stock has followed their devastation of grass and fodder-plants, and much wheat has been destroyed. Breeding in the open plains, and having exhausted the food of their hatching-grounds, they assemble and take flight, seldom rising far from the ground, and in the course of a day's flight may settle many times; but not all together. As the ground is stripped bare, the numbers are increased by local swarms, till a flight may be many miles in width and depth. The flights are invariably followed by crows, hawks, magpies, wood-swallows, and other birds; emus, bustards, and ibises also feed largely upon the locust. The curious whirring noise heard during these flights is due in part to the wings, but largely to a stridulation caused by rubbing a criss-cross sculpture of the hind-leg. A few years back hopes were entertained of destroying locusts by a parasitic African fungus; this was tried in New South Wales, Victoria, and Tasmania, but without appreciable effect, probably through having to be used in hot, dry weather. A local fungoid disease, however, kills off many wingless grasshoppers in some forest districts of New South Wales; in country liable to floods the eggs are sometimes destroyed over large areas by mould.

In Australia, through the attacks of parasites,

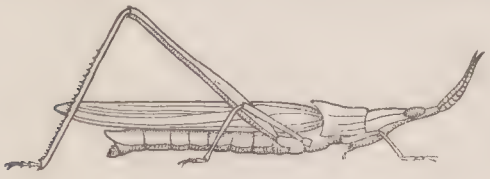
locusts are seldom seriously troublesome two years in succession. From an examination at Queanbeyan of thousands of the common plague-locust, the writer found that some 90 per cent of the females were being destroyed by the maggots of a fly (*Masicera* species), which, living in the abdomen of the locust, destroyed the eggs. Again, the eggs after being deposited in the ground are largely destroyed by chalcid and ichneumon wasps. In America the egg-masses are often destroyed by the larvae of blister-beetles (Cantharidae), but although many of these occur in Australia they have not yet been recorded as doing this useful work. Ants and other insects, too, kill many female locusts when drilling the holes in the ground in which they deposit their eggs. Heavy rollers and hopper-dozers (flat trays with a ridge at the back, drawn by horses) have been used to destroy locusts, and against comparatively small numbers arsenical sprays and poisoned baits may be used.

The Common Plague-locust (*Chortoicetes terminifera*, also known as *Pachytilis australis*) is probably the most destructive Australian species. It occurs in all the States, and in 1891 caused great loss of stock, as well as the destruction of orchards and vineyards in New South Wales, Victoria, and South Australia; waterholes, wells, and other depressions were filled by its numbers, and for two years traces of its visitation were visible. In 1917 and 1921 trains were delayed in Victoria and South Australia, the crushed locusts preventing the wheels from gripping the rails. There are several broods of this species in a season.

The Smaller Plague-locust (*C. pusilla*), with a less extensive range than the first-mentioned species, does a great deal of harm in Australia. Its habits are much the same as those of *C. terminifera*, but when egg-laying the female is usually attended by an irregular ring of males, with one or two in contact with her, head to head.

A very large locust (*Cyrtacanthacris exacta*), measuring up to six inches across the expanded wings, is sometimes troublesome to fruit-trees, tree-cotton and other cultivated plants in the mainland States, but does not appear to migrate in swarms. A still larger, but fortunately rare, species of this genus occurs in Queensland and northern New South Wales.

The Thin Locust (*Acrida turrita*), which has very long hind-legs and flattened antennae, is common in many parts of Australia. It varies in colour from a delicate green with pale stripes



Acrida turrita.

to an almost uniform pale brown. It does not congregate in masses, even when numerous, and makes a curious rattling noise during its short flight.

The Yellow Under-wing Locust (*Gastrimargus musicus*, more commonly known as *Locusta danica*), occurs in all the Australian States as well as in Europe and Asia. It attacks the sugar-cane in northern Queensland, and few cultivated plants escape its attentions. In the mating season flights may be continuous in the same direction for days, though each individual may fly only a few hundred yards before settling. It is a handsome green and brown insect, with a conspicuous patch of yellow, bordered with black, on each hind-wing; these are concealed except during flight. Many other Australian locusts are known. See ORTHOPTERA.

A.M.L.

Grass-trees. (1) This popular name is given in the eastern States to several species of the endemic genus *Xanthorrhoea* (family Liliaceae) which in South Australia (especially on Kangaroo Island) are known as 'yaccas' or 'yuccas,' and in Western Australia as 'blackboys.' There are 13 species, distributed as follows: New South Wales 5, South Australia 5, Queensland 4, Tasmania 3, Western Australia 2. They have a thick stem, which may form a short trunk, or may (as in *X. arborea*) reach a height of 10-12 feet. *X. Thorntoni* is found in the Macdonnell Ranges; *X. pumilio* is a pigmy form from Port Curtis. The long, rigid, grass-like leaves spring in a dense tuft from the crown of the trunk, and from their centre the elongated flower-stem rises to a height of 4-8

Xanthorrhoea hastilis.

feet. The flowers are packed round the apex of the stem in a dense cylindrical spike 1-2 feet long. Several species yield a balsamic resin known as 'grasstree gum,' which has been

tested for picric acid (to be used in the manufacture of explosives); but other more profitable sources of supply have been discovered. The gum is also used in the manufacture of varnish, and paper-pulp has been experimentally manufactured from the fibre. Industrial alcohol has been extracted from the trunk, which has been further investigated for its starch content. The chief source of supply of the resin is Kangaroo Island, whence it is still exported to the United States. The name 'black-boy' was suggested by the rounded trunks, which retain the charred remains of the leaf-bases for years after a bush fire, and with the flowering stem roughly resemble a blackfellow carrying a spear.

(2) The grass-tree of Western Australia is *Kingia australis*, which has the leaves and rounded trunk of *Xanthorrhoea*, but sends up several flexuous stems; the flowers are arranged in globular terminal heads, so that it becomes many-headed. It is known also as 'drum-head' or 'silver-leaf grass-tree.'

Grass-wren. See BRISTLE-BIRD.

Grayson, HENRY JOSEPH (1857-1918) was born at Worrall near Bradfield, in Yorkshire, but spent the last 30 years of his life in Melbourne. A gardener by trade, he interested himself in botany, and particularly in plant microscopy. The problem of testing high-power microscopes led him to construct a machine capable of ruling uniformly-spaced lines on a glass slip at distances down to 1/120,000 inch. These 'Grayson rulings' acquired almost immediately a world-wide reputation amongst microscopists. At a later time he designed and made for the geological department of the university of Melbourne a rock-slicing machine which is probably the most efficient in existence. His last mechanical triumph was a ruling-engine for making diffraction-gratings. Here he achieved a success in advance of that attained by the most accomplished experimentalists in America, backed by almost unlimited resources. This instrument, left, fortunately, in perfect condition at his death, is being used at the university of Melbourne for important researches in optics. He died on 21 March 1918.

W.A.O.

Grease-nut Tree. See LAURACEAE.

Crested Grebe.

Grebes, aquatic birds belonging to the family Podicipidae, found chiefly on lakes, swamps, and waterholes, but occasionally also on bays and inlets of the sea. They differ from all other aquatic birds, except coots, in having each toe provided with its own web. They are expert divers, and feed on small fish, aquatic insects, etc. Their nests are merely piles of floating water-weeds; when the birds leave them, they invariably cover up the eggs with weeds, so that the nest looks like a mere accumulation of vegetable material.

Three species occur in Australia. Two are small (up to 10 inches long), and are often called dabchicks; one of these, the Hoary-headed Grebe (*Podiceps poliocephalus*), is peculiar to Australia and Tasmania, the other, the Black-throated Grebe (*P. ruficollis*), is found throughout the old world. The large and handsome Crested Grebe (*P. cristatus*) has a similar distribution.

Green Arum. See CUNJEVOI.

Greenie. See HONEY-EATERS and WHITE-EYES.

Greenway, FRANCIS HOWARD (1777-1837), was trained in London for the profession of architect, and afterwards practised in Bristol and Bath. According to his own claim, he was connected with 'some of the most extensive concerns in England, public, speculative and private' as well as with 'one of the ablest Improvers of Estates.' Lack of success, however, led him to bankruptcy—possibly he had already contracted what Bigge describes as 'habits of negligence and indulgence'—and for concealing his effects at the bankruptcy he was in 1812 sentenced to 14 years' transportation, and arrived in Port Jackson as a convict on 7 February 1814. At Bath he had gained the sympathy of Arthur Phillip, then near his deathbed; on Phillip's recommendation Macquarie granted him a ticket of leave, and in December he started practice as an architect and expert in the laying out of estates 'as well in the agricultural part as the beautifying.' He had already (27 July 1814) put before Macquarie proposals for a market-house and town-hall worthy of the city they both anticipated. In 1815 (by which time he was 'acting for the Government but not in office or receiving pay') he made proposals still more ambitious; one was for a lighthouse on North Head with a small fort and an auxiliary beacon on the Sow and Pigs reef, another for a large fort on Observatory Hill with an advanced redoubt on Dawes Point and a bridge thence to the northern shore of the harbour. Macquarie, however, found these schemes too magnificent even for his ardent imagination, and insisted that the lighthouse should be built on South Head (where it could easily be reached by land) and the main defence works constructed at the eastern point of Sydney Cove—then known as Bennelong Point, and since as Fort Macquarie; the bridge proposal he discarded altogether. In 1816 Greenway aided the governor to bring to book the contractors for the Sydney hospital buildings, who had scamped their foundations and otherwise failed to carry out their contract; he also pledged himself, if Macquarie would abolish the system of private contracts paid for with the privilege of importing spirits, to erect more and better buildings in four years than had been erected since the colony was founded. This ap-

pealed to the builder-governor, and Greenway was made civil architect and assistant to the inspector of public works. In this position he greatly improved in both style and soundness the buildings that were being erected in and around Sydney, and the best specimens of Macquarie's architecture—the Hyde Park barracks at the top of King-street (now the district court), St. James's church, St. Matthew's church at Windsor, government house in the inner domain (which he modelled on Thornbury Castle, 'only much bolder')—are undoubtedly his. He also devised, but was not allowed to construct, a conduit for the town's water-supply with a branch to Darling Harbour (then called Cockle Bay) for the use of visiting ships, a main drain, a 'Doric screen' connecting the barracks with what is now St. James's church but was at first intended for a court-house, and a systematic plan for the extension of the town—the first Australian town-planning proposal. On 16 December 1817, on which day the Macquarie lighthouse at South Head was completed and the foundation-stone of Fort Macquarie laid, Governor Macquarie celebrated the occasion by emancipating the architect. Earlier in the year he had reported Greenway's appointment to the colonial office, and in 1818 Bathurst confirmed it, but only as a temporary appointment; Macquarie in reply (24 March 1819) laid stress on Greenway's 'Scientific Skill, Judgment and superior Taste,' and asked leave to increase his pay from 3s. a day to 5s., 'Mr. Greenway being now Free and having a large family to support in the Line of Respectability to which they have been accustomed.' Bathurst's only comment was to suggest that, as the duties of civil engineer and civil architect 'appear to be nearly the same,' the offices might be amalgamated and performed by Greenway alone. In 1818 the undaunted architect brought up a proposal for a new church, to stand where the Sydney town-hall now stands, in the middle of a 'four-way circus' with roads to Parramatta, Dawes Point, Darling Harbour and Hyde Park, and digging for the foundations was begun in 1819; but at this stage J. T. Bigge (q.v.) arrived in Sydney and proceeded to attack Macquarie for showing too much hospitality and favour to emancipists, among whom was Greenway. He was forced to admit Greenway's talents as an architect—'as far as they were employed in the public buildings I have mentioned, the benefits derived from them have been very conspicuous'—but accused him of habits of negligence and indulgence, of a disposition to spend too much money on ornamentation (why, thought Bigge, should buildings for convict use be other than plain), and of quarrelling with Major Druitt, the chief engineer; and he recommended the appointment of an engineer officer from England, and the abolition of Greenway's office. He also stopped the work on the new church, and persuaded Macquarie to convert the King-street court-house into a church (St. James's), and build a little way off a school-house which might be used as a temporary court-house (this stood in Castlereagh-street, and was from 1884 until its demolition in 1922 used as a girls' high school).

It was probably this wholesale interference with his work and Macquarie's failure to support him that in 1821 irritated Greenway into a bitter quarrel with the governor, as a consequence of which Macquarie ceased to favour him; Brisbane, adopting Bigge's recommendation, made Major Ovens his chief engineer, and Greenway retired into private practice. The rest of his life is buried in obscurity; the attribution to him of the first designs for St. Mary's chapel (since become a cathedral) is very doubtful. In 1822 and 1825 he unsuccessfully memorialized Brisbane for a title to the house in which he had long lived, and which was claimed by the surveyor-general as government property, and in 1825 published in the *Australian* a series of letters giving an account of his previous work from which much of the foregoing information has been gathered. In 1829 he was refused a clean title to land in Argyle-street which had also been promised him (according to his own account) by Macquarie; but, since Macquarie and Greenway were equally out of favour, nothing less than documentary evidence was reckoned valid by the new officialdom. In 1831, and again in 1836, he claimed 'the original projection of the intended Circular Wharf in Macquarie Place:' in 1834 the *Sydney Gazette* published a long letter from him on the harbour defences: in January 1835 he advertised in the same newspaper that 'Francis Howard Greenway, Architect, Arising from circumstances of a singular nature, is induced again to solicit the patronage of his Friends and the Public.' In May 1837 he applied for registration of a block of land near Morpeth which Macquarie had in 1821 promised him in writing as compensation for work done before his formal appointment as civil architect, and this was granted in November. But before that date Greenway was dead. The exact date of his death is uncertain; all we know is that he was buried at Maitland on 25 September 1837 by the parish schoolmaster, the local chaplain being absent on leave. The land was afterwards granted to his son William. Another son, Charles Capel Greenway, was in 1882-94 archdeacon of Grafton in New South Wales.

Gregory, Sir Augustus Charles (1819-1905), born at Farnsfield in Nottinghamshire on 1 August 1819, was in 1829 brought to Western Australia by his father, who had received a grant of land in the Swan River settlement in lieu of pension when he retired wounded from military service. In 1841 young Gregory entered the colony's survey department, and from 1842 to 1854 was assistant surveyor. In 1846 he made the first of a number of explorations in the interior, which are enumerated and briefly described under Exploration by Land; in their course he discovered coal on the Irwin River and galena on the Murchison. In 1855-6 he headed one of the expeditions sent out to discover traces of the lost explorer Leichhardt (q.v.), and opened up the Victoria River to its source, thence traversing the Northern Territory to Burketown in northern Queensland, and reaching Brisbane via the Gilbert, Burdekin, Fitzroy and Burnett; for this achievement he was awarded the founder's medal of the Royal Geographical Society. In 1858 he made a second attempt to trace Leichhardt, on this occasion travelling through central Australia via the Warrego and Barcoo (which he discovered to be identical with Cooper's Creek) past Lake Torrens to Adelaide. He was then employed to mark the southern boundary of the new colony of Queensland, and on 23 December 1859 was made surveyor-general of that colony.

This ended his exploring period, as for the next 20 years he was occupied with departmental and geological investigations. On 10

November 1882 he was nominated to the legislative council, where almost until his death he did valuable non-partisan work. He was also a trustee of the Queensland museum (1876-99), a member of the aborigines commission (1876-83), and in 1895 president of the Australian Association for the Advancement of Science. It is, however, chiefly for his explorations that he is remembered: he is said to have 'contributed more to the exact physical, geological and geographical knowledge of Australia than any other man,' since his journeys opened up hitherto unknown regions in the four larger colonies and extended east and west the whole length of the continent. He died in Brisbane on 25 June 1905. (C.M.G., 1875; K.C.M.G., 1903.)

A brother, FRANCIS THOMAS GREGORY (1821-1888), also employed in the survey office at Perth, accompanied him on several journeys in Western Australia, in 1858 explored the Murchison-Gascoyne region independently and in 1861 opened up the valleys of several rivers on the north-western coast from the Ashburton to the De Grey. In 1863 he was awarded the gold medal of the Royal Geographical Society. Leaving Western Australia for Queensland in 1862, he was in 1874 nominated to the council, where he took a more actively partisan part than his brother; in 1883 he was for a few weeks postmaster-general in the McIlwraith ministry, and in 1886 led the council's opposition to payment of members. He died at Toowoomba on 24 October 1888. The two brothers in 1884 published at Brisbane their *Journals of Australian Explorations.*

Gregory, SYDNEY EDWARD, born at Sydney on 14 April 1870, played in first-class cricket from 1889 to 1912, and was a member of every Australian team that visited England during those years; he took part also in every test match played in Australia between March 1892 and February 1904, and in those played in February 1908 and February 1912. First taken to England principally for his fielding—he was a great cover-point—he soon developed a great variety of strokes as a batsman; thus in 1890 his average score in test matches was 5, in 1894-5 it was 40. He captained the team that went to England in 1912. In test cricket he has played 92 innings (Hill played 76 and Trumper 74), scoring 2193 runs in all, with an average of 25.8; he has made four centuries, his best being 201 at Sydney in December 1894.—His nephew JOHN MORRISON GREGORY, born at Sydney on 14 August 1895, came into prominence as a member of the A.I.F. team which toured England, South Africa and Australia after the war, making his mark as a fast (right-hand) bowler, a left-hand batsman, and a fieldsman; he is probably the best slip-fieldsman in modern cricket. His career in test cricket began in 1920; in the 1920-1 season he was third in both bowling (24.17) and batting (73.66) averages. Up to the end of the 1923-4 season his test averages were:—batting, 47.33, bowling, 26.38. See CRICKET.

Gregson, THOMAS GEORGE (1791-1874), born at Durham, England, in 1791, migrated to Tasmania in 1821 and embarked on a pastoral life. In 1827 he was active in endeavours to get for the colony liberty of the press, trial by jury, and a representative legislature. He was the leader of the 'patriotic six' who in 1845 resigned from the council as a protest against the doings of Governor Eardley-Wilmot (q.v.). Richmond elected him to the council in 1850, and to the first assembly under responsible government in 1856; carrying a vote against the Champ ministry, he formed a ministry himself in February 1857, but was defeated two months later. He remained an active politician, sitting for the same constituency, till his death on 4 January 1874. During the forties he won local renown as an artist.

Grevillea, a large genus of the family Proteaceae, consisting of shrubs or trees with alternate leaves. It comprises 193 species, a few of which occur in New Caledonia, while all the rest are endemic in Australia; in size, form and structure these show more variation from normal family type than is usual even among Proteaceae. The corolla-lobes are usually revolute; anthers not stalked, seated on corolla-segments; style protruding from a slit in the corolla-tube before the flower opens; fruit a leathery follicle opening along the upper margins. The genus is divided into numerous sections, resting chiefly upon variable floral characters. Of two larger groups one comprises species with a more or less orbicular cluster of flowers, radiating from the top of a common stalk—as in the grey, red, and white or pink 'spider flowers' of the eastern coastal sandstone; the other has a flattened spike-like inflorescence, with the flowers all turned to one side of the axis—as typified in the Silky Oak (*G. robusta*), q.v. *G. striata* (Western Beefwood)—the fresh timber resembles raw beef—has long spikes of creamy yellow flowers. Its leaves are sparingly eaten by stock, and its timber is adapted for ornamental cabinet work. *G. Hilliana* (White Yiel Yiel) has a timber suitable for veneers. The pendulous *G. asplenifolia* is a graceful shrub with a silvery sheen on the under-side of its prettily cut leaves. It is easily r ised, being very adaptable to soil, climate, and pruning operations. A rare species, *G. Gaudichaudi,* is probably a natural hybrid between the swamp-loving *G. acanthifolia* and the carpet-forming *G. laurifolia* of the sandstone hillsides. All three are found in juxtaposition on the higher elevations of the Blue Mountains. *G. Banksii,* a handsome species with bright ruby-coloured flowers, and a cream-coloured variety of this species, have long been in cultivation.

Grey, SIR GEORGE (1812-1898), born at Lisbon on 12 April 1812 a few days after his father, Lieutenant-colonel Grey, had fallen at Badajos, was educated at Sandhurst and joined the army in 1829 (ensign, 1829; lieutenant, 1833; captain, 1839). After a short term of service in Glasgow he was ordered to Ireland, then disturbed, and while there interested himself in the question of land-tenure and formed the opinion that the alienation of the people from the land was a mistake. In 1833 he entered the senior department of the military college at Sandhurst, but, though very successful as a student, was already losing interest in the army. In 1836 he and a Lieutenant Lushington made the colonial office an offer to conduct an expedition to explore the north-western coast of Australia. The offer was accepted, and they were instructed to proceed to the vicinity of Prince Regent's River and thence towards the Swan. They were to investigate north-western Australia, its resources, and the course and direction of its rivers and mountain ranges; to familiarize the natives with the British name

and character; to search for and record all information regarding the natural products of the country, and all details that might bear upon its capabilities for colonization; and to collect specimens of its natural history. Grey was appointed leader. A vessel was chartered at the Cape of Good Hope, and on 2 December the party reached Hanover Bay. For the history of this expedition see EXPLORATION BY LAND. Its most valuable result was the discovery of the Glenelg River and district, of which Grey wrote, 'I have never seen a richer tract of country than the extensive alluvial and basaltic districts in the neighbourhood of the Glenelg.'

Grey made a careful study of the aborigines, but was quite unable to enter into friendly relations with them. In some sandstone caves near the Glenelg he discovered rock-paintings that showed a comparatively high degree of artistic development, much superior to the undoubtedly aboriginal decorations of other caves near-by. He also noted among the aborigines a few lighter-coloured men, closely resembling the Malay type, who appeared to hold positions of authority.

On 27 April the party left Hanover Bay for the Mauritius, where they were obliged to stay for some months to recover from their hardships. Thence Grey set out for the Swan River to consult Sir James Stirling on the best means of continuing his work; while waiting at the settlement for a suitable vessel, he acquired an extensive knowledge of the native language and was able to compile a vocabulary of the different dialects spoken in the surrounding districts, which was forwarded to England at the end of the year. Having completed his preparations by the middle of February, he arranged for the conveyance of his party and five months' provisions to Shark Bay, whence he proposed to make excursions northward to North-west Cape and southward to Gantheaume Bay; he was finally obliged, however, to walk some 300 miles to Perth to seek help for the rest of his party. In Perth he continued his study of the native language, and the governor urged him to accept the position of government resident at King George's Sound, which was mainly associated with the administration of native affairs. Having learned, however, that the colonial office did not favour further expeditions to the north-west, Grey decided to return to England, and sailed from Adelaide on 11 April 1840. On his way home he prepared for the colonial office a memorandum on the treatment of Australian aborigines in which he urged that British law should be extended to govern not only the relations between natives and whites but also those between native and native; that a first violation by a native of the law (of which he was presumably ignorant) should be punished lightly, but with warning of a severe punishment for a second offence; that a mounted police force should be organized to protect the out-back settlers, who would then have no excuse for acts of vengeance; and that substantial rewards—preferably in the form of land grants—should be made to settlers who succeeded in educating natives to steady industry as well as to the natives who submitted to the process.

Grey arrived in England in September 1840, and was preparing his notes for publication when he was invited to take over the administration of South Australia. Having sold his army commission and made arrangements for the publication of his book (*Expeditions of Discovery in North-west and West Australia*), he set out for his new sphere of usefulness, reaching Adelaide on 14 May 1841. He found the colony bankrupt, his predecessor Gawler (q.v.) having pursued a public works policy which he had not the funds to carry through. Grey at once made drastic cuts in administrative expenses, and appointed a board to discover why over two thousand unemployed were receiving support from the public funds; on its report he cut down the dole until its recipients were practically forced to take employment in the country districts. At the same time the financial crisis forced many land-speculators to dispose of their holdings at a reasonable price to *bona fide* squatters and farmers, who willingly provided employment for the labourers from Adelaide. For surveys, road-building, etc., Grey drew on the revenue from land-sales instead of reserving this entirely for immigration expenses; and G. Fife Angas (q.v.) helped him greatly by sending out a good class of agricultural immigrant. The result of these measures was that between 1840 and 1843 the acreage of cultivated land increased from 2503 to 28,960, and the rural population from 6121 to 11,259, while the population of Adelaide decreased from 8489 to 6107. Besides this, the discovery of copper at Kapunda and Burra Burra helped to restore confidence, though it had little direct effect on the revenue until 1845. During this period of financial difficulty Grey retained the confidence of the colonial office. Nor was he less successful in his administration of native affairs, where he gave effect to his recommendations of 1840. He reversed Gawler's policy of treating natives beyond the settled districts as outside the Queen's allegiance, and brought them within reach of the law. In justice to those who were tempted to attack overland parties having only a weak escort, he required that such parties should be efficiently escorted, and stationed E. J. Eyre (q.v.) at a settlement in the interior to maintain order. He also induced some adult aboriginals to take a share in regular industry, established boarding-schools for native children at Walkerville and Encounter Bay, and rewarded settlers who demonstrably gave regular assistance to natives; but this policy was not continued after his departure. The colony having been set on its feet, the colonial office found other work for Grey. Both his financial and his native administration testified that he was the right man to rule New Zealand, which was distracted by repeated quarrels between the Maoris and the white settlers and between the New Zealand Company and the government. In November 1845 he became lieutenant-governor of New Zealand, and by conciliating the tribes that were at all friendly and hitting hard those that preferred to remain hostile soon established peace with the Maoris. The Company he dealt with in an analogous fashion; its defeat took longer, because it had powerful friends in London, but was effected in 1847. On 1 January 1848 Grey was made governor-in-chief over the islands of New Zealand; on 13 September 1852 he became governor of the colony of New Zealand, under a constitution mainly of his devising. At the end of 1853 he took leave of absence and returned to England, where the friends of the defunct New Zealand Company attacked him bitterly; but he soon justified himself to the colonial office, and was sent in 1854 to govern the Cape Colony. His tenure of office there was marked by (*a*) the restoration of peace with the Kaffir tribes by

methods such as he had used with the Maoris, (*b*) the introduction of German settlers of excellent quality, many of them ex-members of the German Legion that had been recruited for the Crimean war, (*c*) the campaign in favour of federation of the South African colonies which he carried on against the wish of the colonial office, and which directly occasioned his recall from the Cape in 1859. Also noteworthy was his prompt acceptance of responsibility when in August 1857 he received from India news of the outbreak of the Great Mutiny. Within three days he had despatched all the troops and military stores that South Africa could spare; immediately thereafter he seized on a body of troops that was on its way to the war in China, and insisted that it should be diverted to Calcutta—'this accidental reinforcement,' Lord Malmesbury wrote afterwards, 'probably saved India.'

In 1859, as has been said, the colonial office recalled him for having advocated federation; before he reached England, a new ministry was in power, and the new colonial secretary at Queen Victoria's request reappointed him to the Cape—but with the proviso that he must drop federation. Early in 1860 he returned to Cape Town, with the promise that at the end of his term he should be sent to Canada. But in 1861 New Zealand was in turmoil, and it seemed that only Grey could master the warring elements. Without demur he accepted the new burden, and landed in Auckland on 26 September 1861. The rest of his life was devoted to New Zealand—at first as governor (1861-8), then, after a few years of comparative quiet in England, as statesman; in 1874 he was elected by Auckland to the house of representatives, in 1877-9 he was premier of the colony, and for the rest of his life the inspirer of reforms and the trainer of younger politicians. John Ballance and Richard Seddon were two of his most notable pupils, and many of their contributions to New Zealand legislation—adult franchise, compulsory repurchase of private estates for closer settlement, triennial parliaments, taxation of land values—were largely inspired by him. In 1891 he was a delegate from New Zealand to the Australian federal convention of that year, and helped to secure manhood suffrage as the proposed federal franchise. His strength now failed him; in 1894 he went back to England, and died there on 20 September 1898.

Grey's work in three great colonies is his best memorial. But he left also to Cape Town a remarkable collection of books and manuscripts, and to Auckland another. His written work comprises two aboriginal vocabularies, the journal of his Western Australian explorations, and a valuable treatise on *Polynesian Mythology and Ancient Traditional History of the New Zealand Race* in which he collected a great number of Maori legends. His character, which impeded his progress as steadily as it enhanced his reputation, is thus summed up by William Pember Reeves, a colleague of his pupil Ballance:—'Against noble aims and a real love of lofty principle, against a life untainted by corruption or the grosser forms of self-seeking, must be set notable faults—the faults of a bold temperament and of an acute man of action, most of whose life was spent in command or controversy.' (K.C.B., 1848; P.C., 1895.)

Grey Jumper or **Apostle-bird,** rather a large perching bird (*Struthidea cinerea*), peculiar to Australia, of very doubtful affinities, but sometimes placed in the family of crows (Corvidae). It is grey, with pale brown wings and black tail, and with a short, arched bill. It is an inhabitant of the drier inland districts of eastern Australia, where it frequents trees, jumping from branch to branch. As it jumps,

Apostle-bird.

it throws up and spreads the wings and tail, and utters a harsh, unpleasant note. It is usually seen in small parties, and the name apostle-bird or 'twelve apostles' is derived from this habit. The same names are sometimes applied to the babblers (q.v.) which have a similar habit.

Grey jumpers feed on insects, especially large beetles. The nest is a deep basin of mud, lined with fine grass, and placed on the horizontal limb of a tree; and the eggs (which number from five to seven) are white, blotched at the larger end with brown, purple and grey. The nest is strikingly similar to that constructed by two other anomalous Australian birds, the magpie-lark (q.v.) and the chough (q.v.). W.B.A.

Grey Nurse. See SHARKS.

Grien, HENRI (1844-1921), born at Yverdun in Switzerland in 1844, first sprang into notoriety when—as Louis de Rougemont of Bordeaux—he reached London from New Zealand with a story of wild adventures on the north-western coast of Australia. At some time during the seventies of the last century he had been valet to a colonial governor; in 1878-9 he was a photographer at Port Douglas; then he became cook on a pearling schooner, and picked up from the crew stories of out-back adventure and a superficial knowledge of nautical affairs. Early in the nineties he drifted into Sydney and became waiter at a small restaurant in Newtown, there meeting Harry Stockdale (q.v.), an experienced bushman who during the eighties had explored the region behind Cambridge Gulf. Grien was also an inventor, and managed to get trial made of a diving-bell which dived once for all to the bottom of the harbour and drowned the two men in it; for this and other reasons the police began a search for him, and he slipped away to Wellington in New Zealand with some of Stockdale's journals, joined a group of spiritualists, and to impress them concocted from the journals and his pearling experiences strange stories of undiscovered islands and white women held in captivity by the aborigines. Failing to secure support in New Zealand, he made his way to London, arrived there in March 1898, and unloaded his budget of fables on the *Wide World Magazine*, then young and avid of sensation. His fame grew rapidly, and he was asked to lecture on his alleged explorations be-

fore the British Association for the Advancement of Science. Among untravelled English folk who could believe anything of far-away Australia, his tales were accepted without question—indeed, many of them were true, having been drawn either from Stockdale's journals or from the pearling episode. But his personal ignorance of the Australian bush was abysmal; and, when a few Australian residents of London heard him talk about 'flocks of wombats rising in the dusk' and similar miracles, the bubble burst. He then turned to itinerant lecturing, and abandoned his claim to truthfulness, allowing himself to be advertised in South Africa (in 1899) as 'the greatest liar on earth.' A subsequent lecture tour in Australia failed altogether, and he disappeared. But during the Great War he reappeared as an inventor, and seems to have made money out of a patent food to replace meat. In 1920, his health failing, he was admitted to the London Homoeopathic Hospital, and on 10 June 1921 died in the Kensington workhouse. His pseudonym 'de Rougemont' was borrowed without leave from a friend of the governor whom he had valeted. W.J.

Griffith, Sir Samuel Walker (1845-1920), born on 21 June 1845 at Merthyr Tydvil in Wales, was brought by his parents to New South Wales in 1854; they lived for a time in Ipswich (Q.) and Maitland (N.S.W.), and then settled in Brisbane. Young Griffith was educated at the university of Sydney (B.A., 1863; M.A., 1870) and gained therefrom the Mort travelling fellowship. After continuing his education in Europe by this means, he returned to Brisbane, was articled to Arthur Macalister, and in October 1867 was called to the bar of Queensland (Q.C., 1876). Soon acquiring a large practice, he could not rest content with his profession, but in November 1871 entered the Queensland legislative assembly as member for East Moreton, and on 3 August 1874 became attorney-general in the third Macalister ministry; for about ten weeks his future political antagonist-in-chief, Thomas McIlwraith (q.v.), was a colleague of his in this ministry. For the next five years he was continuously in office—as attorney-general and secretary for public instruction in the Thorn (1876-7) and Douglas (1877-9) ministries, and after September 1878 as secretary for public works under Douglas. With the defeat of Douglas began Griffith's ten-years' contest with McIlwraith, the latter holding office in 1879-82 and 1888-9, Griffith—who in those years led the Liberal opposition—forming his own ministry on 13 November 1883 and remaining premier until 13 June 1888. From 12 August 1890 to 13 March 1893 he was nominal head of a coalition ministry, with McIlwraith as his chief colleague, and on 14 March 1893 retired from politics to become chief justice of the colony.

These 22 years of political strife included a great deal of useful legislative work. In his second session, long before he took office, he fathered two acts, one a reform of equity procedure. While in the Macalister ministry he carried the important state education act of 1875, on which the Queensland educational system is based, and in the Thorn ministry was the colony's first secretary for public instruction. In 1876-7 he was mainly responsible for acts restraining the inflow of Asiatic and African immigrants to new goldfields—an early phase of the restrictions on alien immigration that have since become the normal Australian policy. His term in the Douglas ministry resulted in the local government act of 1878, the basis of all later measures on that subject. During his own term as premier in 1883-8 he passed acts establishing payment of members, throwing open great areas of crown lands to settlement, introducing the trade union system and the principle of employers' liability, and developing effectively his own local government scheme. The coalition ministry was less fruitful, as might have been expected, but included further dealings with crown lands and the appointment of a commission to formulate a scheme for a local university—a proposal which Griffith had made as far back as 1877, and persistently advocated until the university came into being in 1909. He also interested himself in Imperial affairs, attending the colonial conference of 1887 as one of the Queensland representatives, and taking an active part in the settlement of the administration of British New Guinea; at this conference also he brought forward tentatively the question of fiscal preference within the Empire. He had already (since 1880) worked hard for federation, and at the intercolonial conference of 1883 had carried a proposal for the setting up of a federal Australasian council, which in 1885 was embodied in an Imperial act. In 1888, 1891 and 1893 he presided over meetings of this council. He also represented Queensland at the preliminary federal conference of 1890 and at the convention of 1891, of which he was vice-president; he was chairman of the sub-committee which drafted the convention's bill, and the bill was in the main his personal work.

As chief justice of Queensland he took great care to isolate himself from all business of political interest—an isolation the more necessary because on several occasions (1898, 1899-1900, 1901-2) he acted as lieutenant-governor. He took up again the studies in law which had been somewhat interrupted by his political career, and became one of Australia's greatest constitutional lawyers, impressing even the British privy council with the depth of his attainments. In 1899 he completed the codification of Queensland's criminal law. Partly because of his official position, partly because Queensland had lost interest temporarily in Australian federation and was absorbed in disputes over local separation, he took no part in the federation campaign of 1897 and the following years; but he was a keenly interested observer, probably persuaded J. R. Dickson, then premier, to enter the premiers' conference of January 1899, and certainly influenced him—when in 1900 he went to England as delegate from Queensland to see the Commonwealth bill through the Imperial parliament—to advocate the deletion from the constitution of a clause by which no appeals were allowed from the federal high court to the British privy council. The final settlement of the dispute—by which appeals on constitutional questions are permitted only if the high court itself gives leave—was also of Griffith's devising.

When in 1903 the high court of Australia was actually established, Barton with the general approval of politicians and the public offered Griffith the chief justiceship. The choice was of great importance, for two reasons especially. In the first place, Griffith at once set a standard for the court's decisions and behaviour that it would now be almost impossible to alter; 'he prided himself' it has been said, 'on pro-

pounding the law as the expression of common sense in the regulation of all jural relationships.' In the second place, owing to the action of clause 74 of the constitution (the clause whose final form, as has already been mentioned, was due to him), the high court became the interpreter of the constitution in its minutest details, and Griffith's personality—dominant and rather conservative in his later life, and impatient of the many attempts to diminish State powers and enlarge the federal—swayed the decisions again and again. More especially in the new field of arbitration law did he maintain a stand *super antiquas vias* and limit the new court as straitly as might be. Apart from this (doubtless unconscious) bias his judicial greatness was unquestioned.

Apart from his profession Griffith was a constant patron of art and a literary student of great thoroughness. When codifying the criminal law of Queensland, he came to the conclusion that the Italian code was the best in the world, and in order to utilize it to the full studied the Italian language critically, thus acquiring the taste and skill which enabled him to produce a translation of Dante's *Inferno* (Sydney, 1908) in the measure of the original, and at a later date to complete the translation of the *Divina Commedia* (London, 1912). In 1904 he was made a member of the senate of the university of Sydney. In 1919 he resigned the chief justiceship of Australia, and lived quietly at Brisbane until his death, which occurred on 9 August 1920. (K.C.M.G., 1886; G.C.M.G., 1895; P.C., 1901.)

Grimes, CHARLES. Very little is known of Charles Grimes outside his career in New South Wales. He emerges from obscurity when appointed by the lords of the treasury to be deputy-surveyor of roads to the settlement in Australia in November 1790, and disappears again at Montreal in Canada in 1813. Grimes reached Sydney on 21 September 1791, and was despatched to Norfolk Island on 26 October in the vessel that also carried Lieutenant-governor King. On the island he aided Abbott and Piper to put down a mutiny of the New South Wales Corps garrison, but early in 1794 was recalled to Sydney owing to Alt's inability to cope with his work, and was stationed at Parramatta. For some years he was kept busy with surveys of grants near Sydney, except for a trip to Port Stephens in 1795, during which he was nearly killed by a treacherous aboriginal; his 'Plan of the Settlements in New South Wales' made in 1796 (which he signed as 'deputy-surveyor-general') is our most valuable authority for the Phillip-Grose-Hunter land grants, and he was responsible for the lay-out of the main road westwards from Duck Creek to beyond Toongabbie. On 13 April 1801 he was promoted to the surveyor-generalship on account of Alt's infirmity—he had been doing nearly the whole of Alt's work for some years; and in November of that year he went with Barrallier (q.v.) to the Hunter River to complete the survey already made in June by Grant and Barrallier in the *Lady Nelson*. In November 1802 he was again sent off, this time with Robbins in the *Cumberland*, to survey King Island and Port Phillip; King took occasion to describe him in a letter to Banks as 'a kind of mineralogist.' From 22 January to 22 February 1803 he was surveying the shores of Port Phillip, and on 3 February was one of the first party of white men to navigate the Yarra. His report on both the island and the port was unfavourable: indeed, none of his reports on districts outside the original settlement are encouraging, perhaps because he was already in the grip of the 'alarming illness,' on account of which King in August gave him leave to visit England. The six months in England which King named as the extreme limit of his leave spread out to 16, and it was not till 11 April 1806 that Grimes again reached Sydney; but his services had been recognized meanwhile, and he resumed work on a doubled salary. In 1807 he surveyed the Tamar and Derwent rivers, and returned to Sydney to become deeply involved in the Bligh mutiny. He had always been friendly with Macarthur, and King had rebuked him for it; it was at his house that Macarthur was arrested on 16 December, he signed the requisition to Johnston that was put forward as his authority for Bligh's arrest, and he was made judge-advocate on 30 January 1808 by the Johnston clique. On 22 February he was also made notary public to the colony, an office which seems to have carried with it the duty of performing civil marriages. He had previously had a good deal of magisterial experience, King having in 1800 made him resident magistrate at the Hawkesbury; but in his position as judge-advocate he had to admit that he was 'no lawyer—therefore incompetent to give a Law opinion,' and Johnston discovered that he would be more useful as a witness in England than as a judge in Sydney. He was accordingly sent off in the *Dart* on 16 April with Johnston's despatches, reached London in September, and spent the next two years in endeavours to collect arrears of pay; he was warned by the colonial office that his return to the colony would be forbidden and his pay stopped on account of his participation in the mutiny, and in July 1811 gave up hope and resigned the surveyor-generalship. (From one of his letters during this period we learn that he had done survey work for the government for several years before his appointment to New South Wales, but details are lacking.) It is interesting to note that, although the authorities in London refused to let him draw his pay, yet the amount was included in the colony's budget up to the end of 1811. Nothing else is known of him except that in 1813 he was living, 'well and very happy,' at Montreal; this would seem to indicate that he received his arrears of pay in the end.

Groper, a name applied to several distinct types of fish, including the Blue Groper (*Achoerodus gouldii*, for which see WRASSES), the Queensland Groper (*Promicrops lanceolatus*, for which see ROCK COD), and various species of *Epinephelus*, also mentioned under ROCK COD.

A.R.McC.

Grose, FRANCIS (1754-1814), born at Croydon Crooks in Surrey, England, was educated for military service and entered the army in 1775 (ensign, 1775; lieutenant, 1775; captain, 1779; major, 1783; lieutenant-colonel, 1795; colonel, 1798; major-general, 1805), serving in the American war and being present at the engagement on Bunker's Hill. Twice severely wounded in subsequent engagements, he returned to England in 1778 and for a time was employed in the recruiting service. On 8 June 1789 he was ordered (possibly owing to his personal friendship with Nepean) to raise and take command of a corps for service in New South Wales, afterwards known as the New South Wales Corps (q.v.); the ordinary method of

raising such a corps has light thrown on it by Grose's proposal to raise it entirely at his own expense provided he were allowed to nominate the officers and obtain £500 from 'the captain appointed to a majority.' On 2 November in the same year he was appointed lieutenant-governor of the new colony, and having sent on the corps in detachments (most of it as convict-guards in the second fleet) reached Sydney himself on 14 February 1792. For a time he confined himself to his duties as commandant of the corps—though an attempt in October to charter a vessel expressly to fetch provisions for the corps from the Cape of Good Hope foreshadowed the trading autocracy that was soon to follow. But on 11 December Phillip, who had long been overworked and anxious for a holiday, sailed to England and left Grose in command of the whole settlement.

This was unfortunate both for Grose and for the settlement. He was emphatically a military man, devoted to the service and putting its needs (or the needs of its personnel) above all other objects. In his view the prosperity of the settlement could only be assured by establishing everywhere the control of the corps. He therefore (*a*) abolished the jurisdiction of the civilian magistrates except where he himself should specially direct them to exercise it; (*b*) abolished Phillip's system of using convict labour to grow provisions for general use and substituted one under which convict labour was distributed among officers and free settlers (of the latter there were then very few); (*c*) made liberal grants of land to all military officers who wanted it, and allowed them to pick their areas patchwork fashion, without considering the plan of roads, etc., which Phillip had constructed. The narrowness and crookedness of many Sydney streets dates from Grose's time, and contrasts unfavourably with Phillip's admirable scheme for the town. His sincerity in all this there is no reason to question. Hunter, who objected strongly to most of Grose's measures, wrote that in his opinion the distribution of convict labourers among officers who had farms had been 'the principal means by which this colony has arrived at that state of improvement in which I have found it.' But Grose's confidence in the ability and unselfishness of his fellow-officers was misplaced; many of them had taken commissions in the corps mainly because they hoped to better themselves financially, and when they found themselves in the saddle they dropped all pretence of professional zeal and became purely and simply business men. It was because they obtained the practical monopoly of grain-growing, and found it more profitable to convert the grain into alcohol than to sell it as flour, that the notorious traffic in spirits began, which was to harass two governors almost beyond endurance and cause the forcible deposition of a third. It is also to Grose's discredit that he took serious offence at the action of Richard Johnson, the chaplain, in building at his own expense a church for the settlement and then suggesting that some part of the cost might be borne by the government.

Worried by administrative work outside his normal capacity, and by the breaking out of his old wounds during the hot weather, Grose on 16 December 1794 left the settlement in charge of Captain Paterson (q.v.) and sailed for England. There, after a term of rest on half-pay, he was appointed to the staff in Ireland (1798) and subsequently to Gibraltar (1805), invalided home in 1807, and replaced in Ireland in 1809. In that year he applied for the governorship of New South Wales, but it was given to Macquarie. He retained his colonelcy of the corps until 1807. Of his later years nothing is known, but he died at Croydon in June 1814.

His father Francis Grose, artist and antiquary, was an acquaintance of Robert Burns, and is referred to in the well-known lines

'A chiel's amang ye taking notes,
And, faith, he'll prent it.'

Ground-birds and Scrub-robins, terrestrial birds belonging to the genera *Cinclosoma* and *Drymodes*—both peculiar to the Australian region and almost certainly allied to one another, though their true classification is very

Spotted Ground-bird.

doubtful. They have been assigned by different writers to the thrushes (Turdidae), chats (Saxicolidae), warblers (Sylviidae) and babblers (Timaliidae).

Of ground-birds or ground-thrushes (*Cinclosoma*) there are five species, four found in Australia (one extending to Tasmania), and one peculiar to New Guinea. They are mostly inland birds, found among rocks and underwood, of about the size of a thrush, brownish or rufous above, and lighter below. They feed on insects and seeds, and run along the ground with a gait resembling that of the little ground-doves. When disturbed, they usually endeavour to escape by running; if forced to fly, they rise with a whirr of the wings like quail, and fly heavily in a series of undulations for a short distance before pitching suddenly to the ground again. Occasionally they fly up into the lower branches of shrubs. Their note is a low piping whistle. The best-known species are the Spotted Ground-bird (*C. punctatum*) of south-eastern Australia and Tasmania, and the Chestnut-backed Ground-bird (*C. castanotum*) of the inland districts of south-eastern Australia.

Of scrub-robins (*Drymodes*) there are three species, two occurring in Australia and the third in New Guinea and the Aru Islands. They are shy, rather smaller than ground-birds, chestnut-brown above and dirty-white below, usually frequenting stony ground in open scrub country, and spending most of their time moving by fits and starts along the ground. They utter a sharp whistling note. One species, *D. brunneopygius*, is found in the inland districts of the southern States, the other, *D. superciliaris*, in the Northern Territory and northern Queensland.

Both ground-birds and scrub-robins build open, cup-shaped nests of sticks, bark, and leaves on the ground, at the foot of a tree or bush, and lay two or three white or greyish eggs, blotched with brown. W.B.A.

Ground-thrush. See GROUND-BIRDS and THRUSHES.

Ground-wrens and Field-wrens, small birds frequenting open scrub country, belonging to the genera *Hylacola* and *Calamanthus,* both confined to Australia. They are undoubtedly near relatives, but their classification is uncertain; by some writers they are grouped with the warblers (Sylviidae) and by others with the babblers (Timaliidae). There is little doubt that they are related to the scrub-wrens (*Sericornis*).

Both ground-wrens and field-wrens are rather shy, hopping about on the ground or perching on bushes, and generally carrying the tail upright over the back. They have an agreeable note, and build dome-shaped nests low down in a thick bush, or on the ground amongst dense herbage.

The Chestnut-rumped Ground-wren (*H. pyrrhopygia*) inhabits south-eastern Australia; the Rufous-rumped Ground-wren (*H. cauta*) is found in southern and south-western Australia. They are both brown above, white below with brown spots, and with a black band across the tail; the brightly-coloured base of the tail gives these birds their English name. The Field-wren (*C. campestris*) occurs in southern, central and western Australia, the Striated Field-wren (*C. fuliginosus*) is found in Tasmania and south-eastern Australia, and the Rock Field-wren (*C. montanellus*) in the south-west. They are brown above and whitish below, with blackish streaks almost all over them, and with a black band across the tail. They emit so strong a scent that game-dogs stand to them as to quail; thus they may be regarded as the very smallest of game-birds. W.B.A.

Grunter. See SILVER PERCH.

Grylls, JOHN COUCH (1796-1854), born in 1796 and educated at Dublin and Cambridge, entered the ministry of the Church of England, and in 1838 proceeded to Sydney to serve under Bishop Broughton. On 11 September 1838 he was appointed to the charge of the Church of England at Port Phillip, and reached Melbourne on 11 October; his first services were conducted in a small wooden building near William-street, and close to it on 6 November 1839 was laid the foundation-stone of St. James's church, which for many years was used as the cathedral of the diocese of Melbourne. Within a few weeks of his arrival Grylls had been made by Lonsdale (who was then in charge of the district) a trustee of the local savings bank. But his stay in Melbourne was short; by 1840 he was back in England to bring out his family, and on returning to Australia was made locum tenens at St. Philip's, Sydney, for Dr. William Cowper (q.v.) who was forced to visit England for eye-trouble. On Cowper's return Grylls became his curate, and soon afterwards was chosen one of the first canons of St. Andrew's cathedral. In October 1847 he retired, and went back to England, where he died on 22 April 1854.

Guardfish. See GARFISHES.

Gudgeons, members of the family Eleotridae, and near relatives of the gobies. These small fish occur in the sea, estuaries, and fresh water. Some even inhabit the streams and waterholes of the central Australian desert region; these have the power of aestivating during periods of drought—that is, by suspending animation while lying encased in dry mud, they survive until the return of wet weather revives them. One small species of the genus *Carassiops* is occasionally lifted from shallow pools by whirlwinds and, together with shrimps and water-snails, is carried alive for short distances, to be dropped as from the clouds; such an occurrence is sometimes noted in the press as a 'rain of fish.' Most of the numerous species occurring in Australia are but a few inches in length, but some are large enough to be useful as food-fish, and one (*Oxyeleotris lineolatus*) attains a length of 19 inches. A.R.McC.

Guerard, EUGENE VON. See ART.

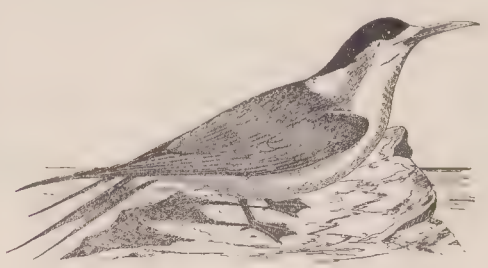
Guettarda, a tropical genus of the family Rubiaceae, consisting of shrubs. The only species indigenous to Australia, *G. speciosa,* is a coastal plant 5-6 feet high with large, fragrant, stalkless flowers scattered along the branches. The fruit is a drupe. In India a perfume is distilled from the flowers.

Guinea-a-week. See PILOT-BIRD.

Guitar-fish. See SHOVEL-NOSED RAYS.

Gulls, Terns, and Skuas, water-birds of the order Lariformes, which frequent sea-coasts, large lakes, and rivers. Gulls proper (Laridae) are represented in Australia by two species only; of these the Silver Gull (*Larus novaehollandiae*), a small white species with silver-grey wings and red beak and legs, is common all round the coast and extends to New Caledonia and New Zealand, but the Pacific Gull (*Gabianus pacificus*), a much larger form with black back and wings and a very strong yellow beak, is found only round the coasts of southern Australia and Tasmania.

Terns or sea-swallows (Sternidae) are much more numerous (16 species) on the Australian coast, and, though classed as sea-gulls in popular parlance, differ from them markedly in appearance and habits. Gulls are scavengers, with shortish, rounded bills and rounded wings and tail; terns have sharp, pointed beaks, pointed wings and forked tails, and live entirely on fish, for which they dive while flying. The largest is the Caspian Tern (*Hydroprogne caspia*), which nearly equals in size the Pacific gull, and has a stout red bill. It is widely distributed on Australian coasts, though nowhere very plentiful, and is also found through the greater part of the world. The commonest is the Crested Tern



Crested Tern.

(*Thalasseus bergii*) a large species with a black crest on its head, and a yellow bill. It is found throughout the western Pacific and the Indian oceans. The little fairy terns or ternlets are also common, the species found on the southern

TERNS' EGGS

Plate XVII

Drawn by N. W. Cayley and F. S. Rodriguez.

1 and 2. Noddy (*Anous stolidus*).
3. Grey Noddy (*Procelsterna cinerea*).
4. Lesser Noddy (*Anous tenuirostris*).
5 and 6. Whitecapped Noddy (*Anous minutus*).
7, 8 and 9. White Tern (*Gygis candida*).

coasts (*Sternula nereis*) being peculiar to Australia; on the eastern and northern coasts is found another species (*S. albifrons*) which ranges over the greater part of the old world.

Terns usually breed in colonies on small islands or sandbanks, placing their eggs in a hollow on the ground. On the islands round our northern coast-line some species occur in immense numbers, particularly the Sooty Tern (*Sterna fuscata*) and the Noddy (*Anous stolidus*). The latter is remarkable among terns in that it builds a nest of seaweed on the tops of bushes. Still more remarkable are the nests of the Lesser Noddy (*Anous tenuirostris*), which builds a fairly compact structure of seaweed in the branches of mangrove-trees. This last species nests only in the Houtman Abrolhos group and in the Seychelles. In 1841, when the birds were discovered on the Abrolhos, they were in immense numbers, and flights of them were said to darken the air. Since that time they have steadily declined in number, and are evidently on the road to extinction; the cause of this is not known.

Several species of tern usually inhabit lakes and large swamps, being often found far from the sea. In Australia the Gull-billed Tern (*Gelochelidon nilotica*) and the Marsh Tern (*Chlidonias leucopareia*) are the principal inland forms; both species occur in similar localities throughout the greater part of the world.

Skuas (Stercorariidae) are stout, dark-coloured, gull-like birds with hooked beaks. They pursue other sea-birds, making them disgorge their prey, which is caught by the pirate before it reaches the water. Two species are regular visitors to Australian seas, one the Antarctic Skua (*Catharacta lonnbergi*)—in New Zealand known as the Port Egmont hen—a winter visitor which breeds farther south, the other the Arctic Skua (*Stercorarius parasiticus*), a summer visitor which breeds in the arctic regions during our winter.

W.B.A.

Gums. See EUCALYPTUS.

Gunn, RONALD CAMPBELL (1808-1881), born at Cape Town on 4 April 1808 (his father being a lieutenant in the garrison there), was educated in England for the army and attached to the royal engineers' office at Barbados, but in 1829 migrated to Tasmania, where he was made superintendent of convicts (1830) and police magistrate at Circular Head (1836). In 1838 he was transferred to Hobart, and in 1839 became private secretary to Sir John Franklin, succeeding Alexander Maconochie (q.v.). In 1841 he left the public service to take charge of a large estate near Longford in northern Tasmania, employing his spare time for the next 14 years in botanical researches; from 1844 onwards he was secretary of the Tasmanian Society and a frequent contributor to its journal. In 1855 he was elected by Launceston to the legislative council, and when the two-chambered constitution came into working in 1856 was returned to the legislative assembly by Selby. From 1860 to 1876 he held minor official posts at Launceston, and in 1864 was appointed by the Tasmanian government (at the request of the government of New Zealand) one of three commissioners to choose the New Zealand capital. But his life's work and the service for which he is chiefly honoured in Tasmania was scientific investigation. In 1854 he was elected a fellow of the Royal Society; Joseph Hooker and William Harvey were his firm friends and admirers; a genus and more than 50 species of Australian plants were named after him, most of them by Hooker. He died at Launceston on 13 March 1881.

Gurnard Perch. See RED ROCK COD.

Gurnards, fishes of the family Triglidae; they abound in Australian waters, but are mostly so small as to be of little value commercially. All gurnards have the head encased in a bony armament, and there are often some bony plates covering the body also. Characteristic are the lower rays of the pectoral fins, which are free, thickened and curved, and serve as limbs upon which the fish creeps about. The upper part of the pectoral fin is greatly enlarged, and ornamented with marvellously brilliant colours, such as large black ocelli with rings of green, blue and gold. The so-called Flying Gurnard (*Pterygotrigla polyommata*) of southern and south-eastern Australia gets its name from its particularly enlarged pectoral fins; but it lives in depths of 50-100 fathoms and is quite incapable of flight. It is of a beautiful pink colour, and, being taken plenti-

Flying Gurnard.

fully by trawlers, has become a well-known food-fish. Another species, the Red Gurnard (*Chelidonichthys kumu*) is likewise seen in the markets, but less plentifully than the other; various representatives of the genera *Paratrigla* and *Lepidotrigla* are captured in the trawl, but are too small to be of value as food-fishes.

The true Flying Gurnard (*Dactyloptena orientalis*) belongs to an allied family of which all the members inhabit the tropics. They have greatly enlarged pectoral fins, which enable them to leap from the water and glide rapidly through the air like true flying-fish. Several species recorded from Australian waters are beautifully ornamented with brown markings, and the head and body are covered with wonderfully sculptured bony plates and scales.

A.R.McC.

Gurnet. See RED ROCK COD.

Guttiferae, a tropical family of trees. One species—*Calophyllum inophyllum* (Alexandrian Laurel or Dilo), a handsome forest tree which thrives best in coastal situations—is indigenous to northern Australia. It is grown for shade and for its fragrant flowers, but especially for the fruit; from this an oil is extracted, which in India and Fiji is used both as an illuminant and to cure rheumatism; when freed

from resin it makes an excellent soap. It also mixes well with pigments. The tree yields a useful timber.

Gymea. See AMARYLLIDACEAE.

Gymnostachys, a genus of the family Araceae, consisting of one species, *G. anceps* (Settlers' Twine), which is endemic in Australia. It is an erect herb with tuberous roots and long, narrow, tufted leaves. The flowers are small, loosely packed in slender spikes, the petals and sepals represented by 4 scale-like segments; flower-stems flattened, carrying clusters of 3-4 spikes some distance apart on the upper portion, each cluster subtended by a rigid, erect, leafly bract; fruit an oval berry. The plant yields a coarse fibre, often used for some purpose where particular strength is required, e.g. sewing up bags or tying the legs of pigs for market; hence the popular name. Before using, settlers usually singe the leaves by drawing them over hot ashes.

Gypsum is found in New South Wales, Victoria, South Australia and Western Australia, but until 1921 was not commercially exploited except in Victoria and South Australia. The Victorian deposits near Boort (between the Loddon and Avoca rivers) have been worked steadily for many years, and are becoming exhausted: in 1902 3227 tons were raised there, in 1922 only 331 tons. Fresh deposits have been opened up on the lower Loddon at Lake Boga and westwards as far as Lake Tyrrell, and the total Victorian production in 1922 was 6945 tons. In South Australia the deposits in the southern end of Yorke Peninsula have also been worked for many years at Lake Fowler and Marion Bay; recently large deposits were discovered near Penong inland from Fowler's Bay on the Bight.

Since 1921 the New South Wales deposits have been slowly opened up, chiefly near Hay on the Murrumbidgee and Hillston on the Lachlan; a third field was opened in 1925 between Bourke on the Darling and Wanaaring. In Western Australia gypsum is widely distributed; it occurs usually near salt lakes of the arid non-tropical interior, especially Lake Austin on the Murchison goldfield and Lake Seabrook north of Southern Cross. Little exploitation has yet been effected. The following figures will illustrate the progress of the industry:—

	1917	1920	1922
	tons	tons	tons
New South Wales ..	——	——	1692
Victoria	1187	3393	6945
South Australia	12,776	40,192	45,241
Western Australia	——	——	63

Besides its use in making high-grade plaster of Paris and cement, gypsum is of value as a fertilizer, especially in irrigation districts.

H

Hackett, Sir John Winthrop (1848-1916), born in Ireland, educated at Trinity College, Dublin (M.A., 1873; hon. LL.D., 1902) and called to the Irish bar in 1874, practised for a time in Dublin. Migrating to Australia, he was admitted to the New South Wales bar, but soon went over to Melbourne, where he became subwarden of Trinity College in the university. Having been admitted to the Victorian bar, he resigned his position at the university in 1882, unsuccessfully endeavoured to enter the legislative assembly, and at the end of the year left for Western Australia, where he intended to take up land. Next year, however, he became joint owner of the *West Australian* newspaper, of which in 1887 he made himself editor, retaining the position until his death. In 1890 he was nominated to the legislative council, and retained his seat at successive elections. Though he never accepted any cabinet appointment, he was for many years the 'power behind the throne' in Western Australia. To him are due practically all the State's educational and recreative institutions, such as the public library, museum, art gallery, zoological gardens, King's park, and university. Of these various institutions he was chairman or president; and he was the first chancellor of the university, occupying that position until his death. He was a member of the federal conventions of 1891 and 1897-8, which framed the constitution; in 1895, 1897 and 1899 he was a delegate to the federal council of Australasia. He died in February 1916. (Kt. Bach., 1911; K.C.M.G., 1913.) J.S.B.

Haemodoraceae, a family of herbs endemic in Western Australia, though one genus (*Haemodorum*) is found outside that State, ranging from Western Australia across the continent and extending to Tasmania. The thickened base of the erect stem, swollen and somewhat bulbous, is enclosed in the persistent sheathing bases of the leaves; flowers black, red, green, or yellow, frequently fragrant. A red exudation from the roots has given rise to the popular name 'blood-root.' The thickened bases of the stems of several Western Australian species are used as food by the aborigines. See Kangaroo Paws.

Haines, William Clarke (1807-1866), born in England and educated for the medical profession (he practised there for some years as a surgeon), in 1848 migrated to Victoria, took up farming on the Barrabool hills near Geelong, and in 1851 was nominated to the new council as a non-official member. In 1854 he succeeded J. V. F. Foster as colonial secretary, held office till the introduction of responsible government, became (after minor mishaps and intrigues) first premier under the new constitution, and held this office, with one slight interval, from 28 November 1855 to 10 March 1858—for the last year in partnership with James McCulloch. Deprived of office, he spent three years in European travel, and returned to accept the treasurership under his old opponent John O'Shanassy, the link being an objection to undenominational State education. The coalition lasted from 14 November 1861 to 27 June 1863, when it was defeated on its land administration. Haines retired into private life, and died on 3 February 1866. Although his ministry carried the universal manhood suffrage act of 1857, he was by temperament conservative and slow of thought; his value to the community lay rather in his unquestioned integrity, and his example of courteous patience in times when the machinery of politics was new and its would-be drivers often vehement and rash. Some authorities identify him with William 'Charles' Haines who in 1843 was a member of the Grant district council. If so, he migrated to Victoria in or before 1843.

Hair-tails, long, ribbon-shaped fishes of the genus *Trichiurus,* silvery in colour and with the body drawn out into a long pointed tail. Several closely allied species occur in temperate and tropical waters of both hemispheres; one occasionally appears in plenty off the coast of New South Wales, apparently coming from deep water, and another swims in small schools among the mangroves of northern Queensland. The New South Wales species is commonly confused with the true ribbon-fish and the frost-fish, but is quite distinct from both. A.R.McC.

Hakea, a genus of the family Proteaceae, consisting of shrubs or (rarely) small trees, with 107 species all endemic in Australia. The corolla-tube is curved (rarely straight), the segments cohering above after the tube has opened; fruit a hard woody capsule, opening in two valves; seeds 2, compressed and produced into a broad membranous wing; leaves alternate, diverse in shape from flat to cylindrical. The section with cylindrical leaves includes the prickly 'needle-bushes.' *H. lorea* (Western Cork-tree) has leaves two feet long; *H. saligna* (Willow-leaved Hakea), an eastern species, is a small tree of 15-20 feet, with fragrant flowers. All species are readily propagated from seeds. See Needlewood.

Hale, Matthew Blagden (1811-1895), born in 1811 at Alderley in Gloucestershire, was a descendant of the celebrated judge Sir Matthew Hale. Educated at Trinity College, Cambridge, he entered the Anglican ministry (deacon, 1836; priest, 1837), and after ten years of parochial work in England was persuaded by Bishop Short (q.v.), who had just been appointed to Adelaide, to come out with him as archdeacon. Arriving in December 1847, he almost immediately founded a school for aboriginal children, which in September 1850 he transferred to land he had bought at Poonindie near Port Lincoln. For seven years he super-

intended this school, but in 1856 resigned his archdeaconry to take up episcopal duties at Perth in Western Australia, of which he was the first bishop (consecrated at Lambeth on 25 July 1857). After a long administration, during which he founded many churches and schools—including 'The Bishop's School' at Perth (now the high school), opened on 28 June 1858—he was translated to Brisbane in 1875 on the unanimous nomination of the Australian bishops. During the eight years of his Brisbane episcopate he devised and organized the diocese of North Queensland, and established a superannuation fund and a home mission fund, aiding the latter repeatedly with generous personal donations. He resigned in March 1885, returned to England, resumed parochial work in Gloucestershire, and died on 5 April 1895.

Half-beak. See GARFISHES.

Halibut. See FLOUNDERS.

Hall, BENJAMIN (1837-1865), born at Breeza in New South Wales in February 1837 and educated as a child at Murrurundi, helped his father on a station in the Lachlan district until 1852, when the elder Hall returned to Murrurundi. Ben Hall then leased a run near Wheogo in the Grenfell district, and soon gained a reputation for honesty and enterprise. But early in 1862 he was suddenly deserted by his wife and charged by the police with highway robbery, though when tried at Orange the jury acquitted him without leaving the box. A few weeks later he was again arrested on the charge of being concerned in the Eugowra gold-robbery (see GARDINER, FRANK). The two arrests and the consequent proceedings occupied nearly four months, and on his return to the station he found his stock either strayed or dead. A few weeks later he was found by the police in company with an undoubted member of Gardiner's gang: they chased and fired upon him, and in desperation he determined to join the gang. When Frank Gardiner towards the end of 1862 disappeared into Queensland, Hall became the gang's recognized leader, and its most famous exploits were carried out under his direction. They included the sticking-up of the Commercial Bank at Carcoar in July 1863, the chase and capture of a detachment of police in August, the raid on Canowindra (which the gang occupied for three days) in September, the daring visit to Bathurst on 3 October and its more business-like sequel of the 6th, the capture and ransoming of Keightley the gold-commissioner on the 24th, and the burning of Goimbla homestead, near Forbes, on 19 November. By that time two of the gang—Burke and O'Meally—had been killed, and a third, Vane, had given himself up: Hall then separated from Gilbert, and during the summer worked alone. But in May 1864 a raid on Koorowatha, between Cowra and Young, disclosed the fact that Hall and Gilbert had again joined forces and obtained a new recruit, Johnny Dunn. Hall now altered his tactics and concentrated on the sticking-up of mail-coaches: of this period some details are given under BUSHRANGING. The *Yass Courier* of 19 November announced cheerfully that he seemed 'to have obtained a lease of the main southern road;' before the end of the year he was robbing drays north of Goulburn: towards the end of January 1865 the gang raided Collector, south of that town, and in March made an unsuccessful attack on the gold escort from Araluen. In April they left the southern district and made back to their old haunts near Young and Forbes, and on 6 May Hall, whose companions had gone ahead of him, was surrounded and shot down by a party of police. Gilbert was trapped and shot on the 12th, and Dunn, though he escaped for a time, was caught at the year's end and hanged on 19 March 1866.

Hall was probably the least brutal of all the well-known bushrangers. It is clear that nothing but domestic misfortunes and what seemed to him police persecution drove him into Gardiner's arms: and a year after he had taken to the bush he was described by a mail-coach passenger as 'a rather tall, robust-looking man with a fine, frank-looking face.'

Hall, EDWARD SMITH (1786-1860), is first mentioned in a despatch from Sir R. Peel (then under-secretary for the colonies) to Macquarie, dated 20 December 1810, as an intending immigrant strongly recommended by William Wilberforce and others. He reached Sydney on 25 October 1812, but failed to gain Macquarie's favour; he apparently knew nothing of farming, and by 1814 had 'commenced merchant' at Sydney and joined Simeon Lord in promoting a company to trade with New Zealand. Already, however, as might be expected of a friend of Wilberforce, he had embarked on philanthropic work, founding on 8 May 1813 the Benevolent Society of New South Wales, of which he was the first secretary. In 1817 he became the first secretary and cashier of the Bank of New South Wales, but appears not to have liked the work, for in 1818 he resigned his position and applied (through friends in England) for leave to practise as an attorney in the local courts; though Bathurst felt compelled to refuse this request of an untrained man, he took the opportunity to repeat Peel's recommendations, and Macquarie compromised by making Hall coroner. When Darling became governor, Bathurst renewed his recommendation—which on this occasion was of no effect. In May 1826 Hall (who was at the time 'needy,' if Saxe Bannister may be believed) issued the first number of the *Monitor*, in which he praised Darling's administration; but by July he was criticizing official proceedings with a severity that drove Darling to prosecute him for libel; and, though that particular prosecution was withdrawn, Hall's outspokenness and Darling's impatience of even reasonable criticism resulted in seven libel actions within a few months afterwards, fines running into hundreds of pounds, and sentences that aggregated three years. Darling was undoubtedly very angry. He denounced Hall as a 'fellow without principle, an Apostate Missionary,' adding—as if somehow that aggravated the offence—that he was a widower with eight young children, and poor. A little later the governor tried to curb the press by imposing a fourpenny stamp duty on each copy. To avoid this heavy impost Hall published the *Monitor* as a weekly magazine, and was prosecuted again. An attack on Archdeacon Scott as 'not a man of peace' brought along another prosecution and more fines, while the archdeacon first locked up and then boarded over Hall's pew in St. James's church. Nor did Darling confine himself to legal proceedings; he deprived Hall of his right to lease pastureland, took away the convict servants who had been assigned to him, and forbade the employees of the government printer to employ their spare time in getting out the *Monitor*. This series of annoyances and prosecutions lasted until 1830, when—Hall being at the time in gaol—Darling released him in honour of the acces-

sion of King William IV, and he became paid secretary to the Patriotic Association. Thenceforth Hall disappears from Australian history as suddenly as he came into it. Even his share in procuring, by gallant if not vehement struggles, the freedom of the Australian press is obscured by the better-known achievements of Francis Forbes (q.v.) and W. C. Wentworth (q.v.). But the friend of Wilberforce and Canning, the founder of Sydney's Benevolent Society, and the unbribable and undefeatable opponent of Darling's high-handedness well deserves a fame of his own. He died on 18 September 1860.

Halloran, Laurence Henry, is first heard of about 1790 as conducting the grammar school of Alphington near Exeter in England, where Robert Gifford, afterwards chief justice of England, was one of his pupils. In 1807-11 Halloran was chaplain to the garrison at Cape Town in South Africa, but quarrelled with Lord Caledon, then governor of The Cape Colony, and bitterly attacked General Grey, the commander of the garrison; he was therefore sent back to England, and disappears from view until in October 1818 he was convicted of having forged a frank to a letter and (though a layman) having obtained a curacy thereby. 'He persisted in pleading guilty' says the report of the case, 'because, he said, the only person who could establish his innocence was dead.' As he was a doctor of divinity and had been tutor to several notables of the day, his case attracted attention and was discussed in the house of commons. Transported for seven years to Australia, he reached Port Jackson in the transport *Baring* on 26 June 1819, and found an old Cape Town friend in J. T. Campbell, then Macquarie's secretary. On Campbell's recommendation Halloran received a ticket of leave; but, certain grave charges which he made against the master of the *Baring* being considered by the magistrates false and malicious, his ticket was cancelled and he was assigned as a servant to Simeon Lord, with whom he was already in favour. Having obtained a second ticket of leave, he was allowed by Lord to open a school, and soon became, to use Macquarie's words, 'the best and most admired Instructor of Youth in this Colony.' Bigge —who was acquainted with his English record and astonished to find him teaching boys in Sydney—had to admit that the school was well conducted, remarkably efficient, and preferred by the principal residents to one kept by the official schoolmaster Thomas Reddall.

Whatever Halloran's defects were, he could teach. Brisbane reported in 1825 that he managed his school with much credit to himself, and in a private letter testified to his 'assiduity, ability, and success,' as well as to his good conduct as a citizen and a journalist. On 4 November 1825 he was chosen headmaster of a free grammar school founded by free settlers and military officers; but the scheme failed, and Halloran found himself so debt-ridden that he spent some time in gaol. Set free again early in 1827, he at once put before Darling a proposal for a public free grammar school to be held in Simeon Lord's house in Macquarie Place. Darling snubbed him, and he promptly started a newspaper, *The Gleaner*, whose first issue appeared on 5 April 1827 and its last on 29 September of the same year. Quaintly enough, Darling had hopes that he might intend to support the government against the attacks of Wentworth and Hall; 'he writes well,' the governor told the colonial office, 'though intemperately.' In 1828 Darling made him coroner (unaccountably neglecting to report the appointment to England), but in September of the same year cancelled the appointment because Halloran had quarrelled with Archdeacon Scott and threatened to publish defamatory documents about him. In this case, at any rate, Halloran had extreme provocation; because he had prefaced his Sunday lectures at the court-house with prayers from the Anglican liturgy, not having obtained permission from Scott to do so, his lectures were prohibited, his pew in St. James's church was taken from him, and an appointment with the Australian Agricultural Company that had been obtained for him by John Macarthur was withheld owing to Scott's interference. As a last resource he opened in 1830 a 'memorial office' wherein persons with a grievance against the government might have their wrongs persuasively set forth for official perusal in London. He died on 7 March 1831.

From first to last Halloran's besetting vice was quarrelsomeness. He quarrelled with the Cape Town authorities, and was sent back to England. It was a quarrel with the clergyman whose curate he had been that brought about his trial and conviction in 1818. He quarrelled with the master of the *Baring* (and lost his ticket of leave), with his gaoler in 1826, with Archdeacon Scott in 1828, and in the same year with Father J. J. Therry (q.v.), who refused to accept from him a donation towards the building of St. Mary's church. The bitterness with which his enemies in England pursued him, however, was probably due to the fact that he had during the 1811-17 period by means of forged letters pretended that he was an ordained priest, obtained curacies thereby, and celebrated marriages which were in fact no marriages at all, thus causing great distress to the unfortunate couples concerned.

His son Henry Halloran (1811-1893), born at Cape Town in 1811, was educated at the father's school in Sydney and in 1827 entered the survey office as a clerk. In 1830 he narrowly escaped dismissal for having copied out a memorial compiled by his father for a government contractor who supplied bad bread. Darling wished to dismiss him, but the colonial office was more lenient. Thereafter, pursuing his career through various grades of the public service, he rose in 1866 to be principal undersecretary, and held the post until his resignation in 1878. Outside his work his main interests were military (in 1854-71 he was lieutenant in the volunteer mounted forces) and literary. His verse gained the praise of D. H. Deniehy, but is purely imitative and mildly pleasing; his best service to literature was probably his encouragement of Henry Kendall, for whom in 1863 he obtained a clerkship in the survey office. The verse, scattered through newspapers, magazines, and pamphlets, was collected in 1887 under the title *Poems, Odes, Songs.* Halloran died at Ashfield on 19 May 1893. (C.M.G., 1878.)

Hamilton, Sir Robert George Crookshank (1836-1895), born on 30 August 1836 at Bressay in the Shetlands and educated at University and King's College, Aberdeen (M.A., 1857; LL.D., 1885), in 1855 was appointed to the war office and sent as a commissariat clerk to the Crimea. During a long career in the civil service he served in the office of works (1857-61), the education department (1861-9), the board of trade (1869-78), and the navy office (1878-82). Being then lent to the Irish office to fill the under-secretaryship, he was in

1883 made permanent under-secretary, but removed in December 1886 by the incoming Unionist ministry on account of his home rule sympathies. He was made governor of Tasmania early in 1887, held that post until 1893, and on his return to England was appointed by the then Liberal ministry to various colonial and financial commissions, and in November 1894 made chairman of the board of customs. He died in London on 22 April 1895. An able and industrious civil servant, he had few opportunities during his Australian period for showing his capabilities. (C.B., 1883; K.C.B., 1884.)

Hammer-headed Sharks, members of the family Sphyrnidae, having the head peculiarly flattened, and produced into a broad, flat lobe on each side upon which the eyes are placed. The purpose or value of this extraordinary development is unknown, and it is undoubtedly one of the most remarkable modifications found among fishes. Half a dozen species are known, some of which range over all temperate and tropical seas and, attaining a large size, are dangerous to man. The others are smaller and more restricted in their distribution. Each female produces a large number of young, which are born alive. A common species in Australian waters is *Sphyrna zygaena,* which attains a length of at least 15 feet. A.R.McC.

Hampden, Viscount. Henry Robert Brand, second viscount Hampden (1841-1906), born on 2 May 1841 and educated at Rugby, held a commission in the Coldstream Guards from 1858 to 1861-2, being aide-de-camp to the governor-general of Canada. He was twice a member of parliament, for Hertfordshire (1868-74) and Stroud (1880-6), abandoning politics when he found it necessary to dissociate himself from his leader Gladstone on the home rule question. In 1895 he was appointed governor of New South Wales, but resigned before the regular term (five years) was complete, leaving Sydney on 5 March 1899. During his governorship the campaign for federation was in full swing and ultimately successful, and his sound constitutionalism and unobtrusive advice were all the more valuable because from first to last he kept within the narrow limits of his office. After his return to England he retired into private life, and died in London on 22 November 1906. (G.C.M.G., 1899.)

Hampton, John Stephen (1809-1869), born in 1809, entered the medical branch of the navy, and in 1843 visited Tasmania as surgeon-superintendent of the convict transport *Constant.* Returning to England, he commended himself to the colonial office by his handling of prisoners, especially 'Pentonville prisoners and exiles;' and, when in 1846 it became necessary to appoint a new comptroller-general of convicts to administer a new system in Tasmania, Hampton was the office's immediate choice. He was appointed on 25 May, and reached Hobart in the *Maitland* at the end of November. His administration was efficient, though in many ways cold-blooded. When in 1855 the Tasmanian legislative council opened an enquiry into the conduct of the convict department, Hampton refused to give evidence, on the ground that penal establishments were under Imperial, not local, control; in this contention he was supported by the then governor (Sir H. Young), the local supreme court, and the privy council. On 22 October 1861 he was appointed governor of Western Australia, and reached the colony at the end of February 1862. His administration there was harsh, and created much discontent among the free colonists; but his handling of the convicts was firm and successful, and his public works policy was of great and lasting value to the colony. In 1868, when transportation to Western Australia was abolished, Hampton retired from office, and died in England on 1 December 1869.

Hanson, Sir Richard Davies (1805-1876), born in London on 6 December 1805, educated at Melbourne in Cambridgeshire, and admitted an attorney in 1828, besides practising his profession reported for the *Globe* and *Morning Chronicle,* and lectured in favour of Gibbon Wakefield's colonization scheme for South Australia. In 1835 he was appointed assistant commissioner for an enquiry into crown lands and immigration in Canada; there he acted as private secretary to Lord Durham, and with Wakefield drew up the report that Charles Buller signed. In 1840 he migrated to Wellington in New Zealand, where he was crown prosecutor and edited the *New Zealand Colonist.* In 1846 he moved to Adelaide, secured a leading position at the bar, wrote for the *Register,* and in 1851 entered the legislative council; when his election was petitioned against for technical irregularities, Sir Henry Young made him advocate-general, and thus an ex officio member of the council. This appointment is notable because Hanson was a strong opponent of state aid to religion—which was Young's declared policy—and only accepted the post on condition that he remained free to continue his opposition. In the next few years he devised and carried several acts of high importance—in 1852 a district councils act on which all subsequent South Australian legislation of the kind is based, and an act for the abolition of grand juries that transformed the colony's criminal law (and incidentally angered Judge Boothby, q.v., beyond reason); in 1853 acts reforming the procedure of the supreme court, amending the law of trustees, and dealing with the registration of joint stock companies. The education act of 1851 and the bullion acts of 1852 owed much to his shaping, and the constitution act of 1856 was drafted by him. In the first ministry (Finniss's, of 1856-7) formed under responsible government he was attorney-general, and within six weeks of the defeat of that ministry formed one of his own which lasted until May 1860. During these terms of office he passed the first South Australian patents act, an act abolishing the public execution of criminals, and a bill (which the British authorities disallowed for many years) legalizing marriage with a deceased wife's sister. Though at first an opponent of Torrens's land-registration law, he worked hard to make it effective when once passed and suggested the appointment of Torrens himself to the headship of the registry office. From March 1857 to November 1861 he was one of the members for Adelaide in the legislative assembly; on the latter date he was made chief justice in succession to Sir Charles Cooper, again angering Judge Boothby beyond reason. As a judge he was insistent on the importance of first principles and perhaps over-impatient of technicalities, but few of his judgments were reversed on appeal. In 1869 he visited England and was knighted by Queen Victoria; in 1872-3 he was for six months administrator of the government; and in 1874 he was chosen to be chancellor of the newly founded university of Adelaide, but before he could deliver his inaugural address

died suddenly at Mount Lofty on 4 March 1876. Outside politics and the law his chief interest lay in theological studies, and he published three books that long remained textbooks of rationalism—*Law in Nature* (Adelaide, 1865), *The Jesus of History* (London, 1869), and *Paul and the Preaching of Christianity in the Primitive Church* (London, 1875). (Kt. Bach., 1869.)

Harbours may be classified as natural or artificial. The line of division, however, must necessarily be somewhat arbitrary, since the best natural harbour requires considerable engineering work to enable it to meet the needs of modern commerce, while most so-called artificial harbours have some feature, commercial or geographical, which make them specially suitable as ports of trade or refuge. In proportion to her coast-line Australia has comparatively few natural harbours of first-rate importance, and some of these are too remote from industrial centres to be much utilized. The most notable are:—

1. Port Jackson, one of the finest of natural harbours, since its shores are broken up by steep points that enclose bays which are harbours in themselves, usually with deep water close to the foreshores. Of these the best known is Sydney Cove (Circular Quay) in the heart of the city, used mainly for ferry traffic, though a few non-British mail-steamers still berth there. Walsh Bay, a shallow bight just west of the Cove, is provided with shed accommodation to suit the largest modern cargo vessels; and at Darling Harbour, the next deep bay westwards, are the wharves of the chief inter-State shipping companies, and the main wharves and warehouses connected with the railway system. Woolloomooloo Bay, east of the Cove, has large wharves and a broad central jetty to accommodate big cargo vessels; since 1924 the British mail-steamers have also berthed there. There are about ten miles of wharfage in all, and the chief wharves have from 28 to 40 feet of water. They are reached from the ocean by channels 700 feet wide with a minimum depth of 40 feet at low tide, one for incoming and one for outgoing vessels. Large dry docks at Cockatoo Island, a few miles west of the Cove, belong to the Commonwealth; the largest is 608 by 84 feet with a depth of 32 feet. There are also privately owned docks at Woolwich on the north and Balmain on the south of the Parramatta, of which the former is 765 by 83 feet and 28 feet deep. All these are connected with workshops capable of carrying out repairs to the largest visiting steamships. In 1922-3 8,813,432 tons of shipping entered Port Jackson.

2. Jervis Bay, 82 miles S. of Sydney. On its southern side is an area of Federal territory containing a naval station and the naval college. It extends 8 miles N. and S. and 3 to 5½ miles E. and W., with depths varying from 18 fathoms at the entrance to 6 fathoms within half a mile of the greater portion of its shore. As with the next-mentioned harbour, its connections with the inland districts are as yet too incomplete to permit proper development of its facilities.

3. Port Stephens, 83 miles N. of Sydney and 20 miles N. of Newcastle, a fine harbour whose entrance has a depth of six fathoms (with a small patch of five fathoms at outer end); a large area of the harbour has a depth of six to eight fathoms.

4. Twofold Bay, 208 miles S. of Sydney, situated near the southern boundary of New South Wales. This port is at present suitable as a refuge for vessels of 26 feet draught in southerly weather, but is open to the eastward. It could be made a safe harbour in all weathers by the construction of a breakwater from the southern side in a northerly direction; vessels drawing 30 feet could then be accommodated with a good anchorage, and loading facilities.

5. Port Phillip, which has an area of 31 by 20 miles, with a western arm, Corio Bay, on which stands Geelong. The entrance of the main bay has 36 to 40 feet of water, but with an ebb-tide and southerly wind carries a dangerous 'rip,' caused by a belt of rock with deep water on both sides. There are two main channels, of which the southern is being dredged to 36 feet. The port is in Hobson's Bay, at the northern end of the great bay: the principal accommodation was originally at Sandridge (now Port Melbourne), but since the dredging of the Yarra and the cutting of the Coode Canal the longer wharfage is on the Yarra. Port Melbourne has 8460 feet of wharfage, with 26 to 32 feet depth, utilized generally by mail steamers; Williamstown has 6600 feet, with 17 to 30 feet depth, utilized by oversea cargo vessels; on the Yarra there are 30,450 feet, with 17 to 26 feet depth, utilized chiefly by inter-State steamers—this area includes the Victoria Dock, 96 acres in extent. There is a dry dock at Williamstown and two others on the Yarra, of which the larger is 480 by 50 feet, besides patent slips and floating-docks with their attendant workshops. In 1922-3 7,015,030 tons of shipping entered Port Phillip; but this total is swelled abnormally because, Sydney being the terminus of many oversea lines, their vessels enter Port Phillip twice on each voyage. Geelong is credited with an entering tonnage of 553,689 (1922-3).

6. Western Port, 26 miles SE. from Port Phillip, with an entrance 3½ miles wide and a depth of 12 to 15 fathoms in mid-channel. The harbour is 20 square miles in extent, with a depth of four to eight fathoms. A naval base has been established on the western side.

7. Port Lincoln, near the SW. extremity of Spencer Gulf, with an extent of six by three miles and a depth of five to nine fathoms, and almost landlocked. The principal jetty is 660 feet long. The port is the terminus of the Eyre Peninsula railway, with a rich wheat-growing district at its back. At Cape Thevenard a pier has been built to accommodate oversea wheat ships.

8. Wallaroo on the E. coast of Spencer Gulf, connected with Adelaide by rail. The single jetty is 2820 feet long, with 25 feet of water alongside. In 1922-3 233,046 tons of shipping entered Wallaroo.

9. Hobart, a magnificent harbour, 12 by 2½ miles in extent, with deep water close to the shore. It has 8500 feet of wharfage, with a depth of 26 to 58 feet at low water, besides accommodation for smaller vessels. There is a large export trade in apples, hops, timber and wool; formerly whale oil was exported. In 1922-3 589,248 tons of shipping entered Hobart.

10. Port Arthur on Tasman's Peninsula, of historic but little commercial importance; it is one of the most secure of natural harbours, extending five miles, with 22 fathoms of water in the centre and six fathoms close to the shore. Its lack of communications with any area that could supply trade makes it practically useless.

11. Macquarie Harbour, on the W. coast of Tasmania, with an area of 112 square miles and

depths ranging from 5 to 20 fathoms. The narrow entrance is dredged to 16 feet. Strahan, at its northern end (which is connected by rail with Burnie on the N. coast), has 1000 feet of wharfage with depths of 13 to 18 feet. Kelly's Basin on the SE. shore has 600 feet of wharfage with 12 to 20 feet of depth.

12. Albany (Princess Royal Harbour), which forms the inner portion of King George's Sound, a fine natural harbour (the entrance, about a quarter of a mile wide, has 33 feet of water), connected by railway with Perth. The oversea jetty has 3000 feet of wharfage in 30 feet depth; the coastal steamers' jetty, 2744 feet long, has ample accommodation in 14 to 23 feet of water. In 1922-3 720,007 tons of shipping entered Albany.

13. Derby, at the head of King Sound in Western Australia, near the entrance to the Fitzroy River; it is the port of shipment for live-stock from the rich Kimberley district. The mouth of King Sound (60 miles from Derby) is studded with islands; between them are three passes, through which rush strong tides; the tidal rise is 24 to 30 feet.

14. Port Denison, on which Bowen stands, one of the finest but least used of Queensland harbours, with an entrance depth of 18 feet at low water, and a spring rise of 10 feet. There is ample wharfage, with 23 feet at low tide. In 1922-3 487,454 tons of shipping entered Port Denison.

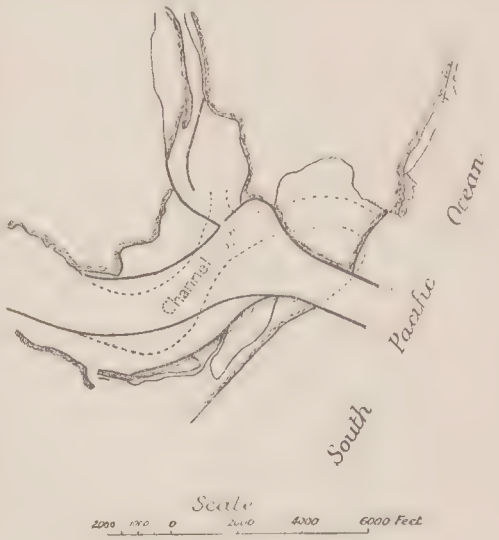
15. Cairns on Trinity Bay, 990 miles NW. of Brisbane, the outlet for a rich sugar, timber, and mineral region. The entrance is dredged to 20 feet at low water (spring rise nine feet). Some 1500 feet of wharfage in 18 to 24 feet of water is connected with the railway. In 1922-3 570,703 tons of shipping entered Cairns.

16. Port Curtis, on which Gladstone stands, a fine harbour with a good oversea trade in frozen and preserved meats. It was for many years the port for transhipment of mails for northern Queensland.

17. Port Darwin, the chief port of the Northern Territory, terminus of the cables of Java, and a port of call for Eastern trade liners. The harbour has 7 to 14 fathoms of water; the jetty, 528 feet long with 22 feet at low water (spring rise 22 feet), is connected with the town by tramway. In 1922-3 99,955 tons of shipping entered Port Darwin.

It will thus be seen that the whole Australian coast-line—over 12,000 miles long—affords at most 17 good natural harbours within anything like convenient distance of the productive country inland. The construction of artificial harbours, often at very great expense, has therefore become a necessity of the situation. These may be divided into two classes—river ports, dependent on training walls and entrance moles, and roadstead ports, in which the natural protection of a headland is augmented by the construction of breakwaters.

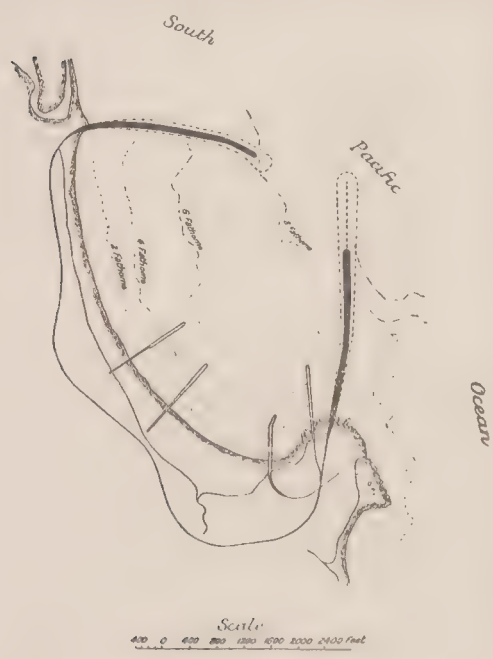
New South Wales. A typical river port has been made at the Richmond River in northern New South Wales. The main difficulty in its construction was to fix the position of the main channel, and especially of the entrance, so that it should be maintained by the tidal currents and not altered or damaged by the not infrequent floods of the river and its principal tributaries. Before the improvement works were started, the position of the entrance had varied within a range of 1¼ miles; on four occasions at least floods broke through the southern sand-spit, and the mouth thus formed became the entrance for shipping. This new channel would gradually work northwards, owing to the action of southerly winds, until it again reached the northern headland. Further, the shifting nature of the sandbars at the river-mouth made navi-



Richmond River port.

gation at all times dangerous, and sometimes impossible for months at a time. The Richmond River is a highway to one of the richest agricultural districts in Australia, with a 62-mile channel to Lismore navigable for steamers with a depth of 12 feet. The chief obstacles to the permanence of these river ports are currents, winds, and floods. Along the New South Wales coast the East Australian current (see CURRENTS) creates an eddy, usually weak, alongshore in the opposite direction; when backed by heavy winds from the south, this return-current gathers great strength and often moves large masses of sand athwart the river entrances. Harbour engineers dread an on-shore gale, as heavy seas accelerated by such a gale greatly increase the sand-barrier at these entrances, and may interfere with (or even prevent) the entrance or exit of shipping. On the New South Wales coast the heavy seas due to south-west and south-east winds do less damage than those raised by direct on-shore (easterly) gales. The mileage of S. winds—according to G. H. Halligan, F.G.S.—is 30,567 miles, against 14,898 miles of NE. winds; but, taking into account only winds of more than 30 miles per hour, the proportion of S. to N. winds (after discarding off-shore winds) is as 36.2 to 1.2. Any effect therefore, of heavy winds along this coast on the direction of littoral drift must be from S. to N. The discharge of upland water must also be considered in designing river entrances. This both effects a scour additional to that produced by tidal action, and is an important factor in deciding how much width shall be left between breakwaters. Where little upland water is available to assist the ebb-tide scour, the tendency is for the entrance to close. If insufficient provision is made for discharge, the flood creates a deep gorge which endangers the safety of the training-walls and breakwaters. A typical roadstead port is found at Port Kembla (45 miles S. of Sydney), the main port of the southern

coal-fields of New South Wales. It is naturally protected by a southern headland, and at first only one—the eastern—breakwater was proposed, 2750 feet long; with the growth of trade, how-



Port Kembla.

ever, it was decided to construct a northern wall, and to create a practically still-water port. Stones of not less than four tons weight were used in the eastern wall, which was faced on the ocean side with blocks of 20 tons and upwards. This breakwater is now being extended 1000 feet. Some difficulty was experienced with the railroad on the top of the wall, as heavy seas tore out the ballast on which the lines were laid and shifted the rails and sleepers out of position. To overcome this difficulty, all packing material above the large stones was replaced by concrete, the sleepers being embedded in the surface concrete, and the railroad was anchored to old rails set in the concrete at a lower level. This method has given great satisfaction. The northern breakwater is constructed of stones not less than three tons in weight, and is protected on its outer slope by heavier blocks. There is still some range of sea at times within the port, but delays from this cause in shipping are now unknown, and loading is carried on when stand-off signals are being displayed at adjacent ports. The area enclosed is 334 acres, as compared with harbours at Dover, 600 acres; Colombo, 500 acres; Chicago, 455 acres; Holyhead, 400 acres; Barcelona, 380 acres; Ymuiden, 250 acres; Kingston, 250 acres; Tynemouth, 240 acres; Madras, 220 acres; Algiers, 220 acres. The depth of water is ample for the largest ships afloat, although the present wharfage will not serve vessels of greater draught than 30 feet.

At Newcastle, the chief coaling port of Australia, the Hunter River has its exit between breakwaters. There are three miles of wharves, and an inner basin about 5000 feet long by 1000 feet wide is now being dredged. The harbour has depths from 23 to 30 feet at low water. The wharves are provided with hydraulic and electric cranes, capable of loading coal at 200 tons per hour. The steel works of the Broken Hill Co. at Port Waratah, large smelting works and the state ship-building yards at Walsh Island have added to the importance of this port. The construction of a large floating dock has been authorized, but the work has not yet been commenced. In 1922-3 4,662,155 tons of shipping entered Newcastle. Among the other New South Wales rivers whose estuaries have been improved is the Clarence River. The entrance is protected by training-walls; the main channel is navigable for vessels of 13 feet draught to Grafton (40 miles); the minimum depth on the bar channel is 12 feet 6 inches. Breakwaters have been built at Cape Hawke, at the entrances of the Manning, Bellinger, and Tweed rivers (the last of which is connected by railway with Brisbane), and at Moruya (180 miles S. of Sydney). At the Nambucca River and at Camden Haven training-walls have been constructed. T.E.B.

Victoria. At Warrnambool in Victoria protection from southerly winds is given by a curved breakwater-pier 1000 feet in length, built of concrete blocks; the western side is covered by a series of islands and rocks. There is a depth of 15 feet alongside the pier. The exports are potatoes, wool and agricultural products. Port Fairy (Belfast), at the entrance of the Moyne River, has two stone training-walls 1500 feet long.

South Australia. Port Adelaide, the third port of Australia, is situated eight miles up the winding river Torrens, but only about two miles in a direct line from the coast. The river is being dredged to a minimum depth of 27 feet, with a width of 250 feet. There are four miles of wharves, with a depth of 16 to 27 feet, and it is proposed to construct six large wet docks for vessels handling cargo. An outer harbour for ocean steamers has been constructed on the shores of St. Vincent Gulf; it has 2400 feet of wharfage with a depth of 33 feet at low water, and one berth, 600 feet long, with a 36 feet depth. In 1922-3 4,065,796 tons of shipping entered Port Adelaide. Port Pirie on the E. side of Spencer Gulf is the port of shipment for Broken Hill ore, and the site of large smelting works. It contains about 6000 feet of wharves situated five miles from the entrance, and is connected with Broken Hill and Adelaide by railway. The channel is 250 feet wide and 18 feet deep, the spring rise being 10 feet. In the harbour there is a swinging basin 1000 by 600 feet. In 1922-3 646,288 tons of shipping entered Port Pirie. Port Augusta, at the head of Spencer Gulf, is the eastern terminus of the federal trans-continental railway, which here makes connection with the State railways of South Australia. The entrance channel for eight miles has a minimum breadth of 200 feet with 18 feet depth at low water; the spring rise is 12 feet. The wharves are 1188 feet long, with a depth of 22 feet.

Tasmania. Launceston on the Tamar, some 42 miles from its mouth, is the second port of Tasmania. There is a minimum depth of 21 feet in the channel, and 3200 feet of wharfage with 16 to 20 feet depth at low water, and a spring rise of 12 feet. In 1922-3 382,315 tons of shipping entered Launceston. Beauty Point is a deep-water (40 feet) port six miles inside the Tamar entrance, and it is proposed to construct another at Ball Bay (7½ miles

from the entrance) in 42 feet of water. Devonport at the mouth of the Mersey has a training-wall 1000 yards long from the E. shore, and a short one on the W. side linking up a group of rocks. A bar of shingle at the mouth has been dredged to a depth of 20 feet at low water; the spring rise is nine feet. Limestone bins here can load at the rate of 1200 tons per hour. There is 1700 feet of wharfage in 14 to 20 feet of water. In 1922-3 359,317 tons of shipping entered Devonport. Burnie on Emu Bay is protected by a concrete breakwater wharf, 1250 feet long, with 40 feet of water at its outer end. There is a wooden pier 600 feet long, where vessels can discharge into railway trucks. Extensions to breakwaters and wharves will provide 3000 feet of wharfage. There are large exports of minerals, especially tin and copper. In 1922-3 461,697 tons of shipping entered Burnie. Stanley is situated on a deep bay protected on the N. and W. by Circular Head. A massive breakwater 700 feet long protects its inner harbour; on the W. the breakwater pier is 551 feet long, with a depth of 15 to 34 feet, besides accommodation for smaller vessels.

Western Australia. Fremantle at the mouth of the Swan River, the chief port of Western Australia, is entirely artificial. It was formed by blasting away a bar that formerly obstructed the entrance, and is protected by a massive breakwater. The harbour is about 1 mile long by 1000 feet wide, with a present depth of 30 feet, which is to be further dredged to 36 feet. About two miles of wharfage is connected with the railway and lighted by electricity; travelling electric cranes facilitate the working of cargo and coal. In 1922-3 2,664,643 tons of shipping entered Fremantle. Slightly to the S. is the site for the proposed Cockburn Sound naval base, a natural harbour sheltered by islands and reefs. Wyndham, the most northerly port in the State, lies up the Ord River 54 miles from Cambridge Gulf. Vessels lie aground on mud at low water. The spring rise is 18 to 24 feet, and the velocity of the ebb-tide seven to nine knots. The exports are cattle and frozen meat. Bunbury is a roadstead protected from the W. by a massive stone breakwater 5015 feet long. There is a wharf 1950 feet long, with berths on each side—the outer 400 feet in 26 feet of water. An extension of this will give 552 feet more length and 22 feet more width, with a depth of 30 feet. The chief export is jarrah timber. In 1922-3 306,891 tons of shipping entered Bunbury.

Queensland. Brisbane, the chief port and capital of Queensland, lies on the Brisbane River, 17 miles from Moreton Bay. The bay is full of sandbanks, through which two main channels have been marked by buoys and leading lights; the very winding river has a channel 400 feet wide, with a minimum depth of 24 feet (now being dredged to 26 feet), and a spring tide of seven feet. Mail steamers use the wharf at Pinkenba, eight miles below the city; at Brisbane itself there is some 14,000 feet of accommodation, with depth up to 28 feet, and a dry dock (430 by 50 feet 4 inches) with 18 feet of depth at high water. In 1922-3 3,121,839 tons of shipping entered Brisbane. At Maryborough on the Mary River, 20 miles from the entrance, there is 1500 feet of wharfage, with 14 to 21 feet of depth; this port is used for inter-State and coastal trade only, the navigation of the river being intricate. The port of Rockhampton on the Fitzroy River, 38 miles above its mouth in Keppel Bay, can be reached only by vessels of moderate draft. Port Alma, at the mouth, is the deep-water berth for this port; it has 1000 feet of wharfage with 25 feet depth at low water, and a spring rise of 13 to 16 feet. In 1922-3 497,388 tons of shipping entered Rockhampton. At Townsville on Cleveland Bay, the chief town of northern Queensland, the roadstead is protected by breakwaters, of which the southern contains 2200 feet of wharfage with 23 to 27 feet depth; there is also a concrete jetty 940 feet long, with 25 feet depth. The spring rise is 8 to 12 feet. In 1922-3 1,172,515 tons of shipping entered Townsville.

Many small ports are available for coastal trade only. Among these are in New South Wales Port Macquarie, Byron Bay and Catherine Hill Bay N. of Sydney, and Bulli, Tathra (the port for Bega), Merimbula and Nelligen S. of Sydney; in Victoria the historic Portland with its rich hinterland, but precarious anchorage; in South Australia the wheat ports on Spencer Gulf (Broughton, Port Germein and Franklin Harbour), and Edithburg in St. Vincent Gulf, backed by the chief salt-producing district in Australia; in Tasmania several ports on the Huon River and D'Entrecasteaux Channel for the trade in fruit, timber and agricultural produce; in Western Australia Geraldton, Carnarvon (Gascoyne River), Onslow, Broome and Port Hedland—the last a landlocked harbour with narrow entrance and strong tide; and in Queensland Mackay, Bundaberg, Lucinda Point, Cooktown (Endeavour River), and Normanton on the Norman River, 55 miles above its entrance into the Gulf of Carpentaria. J.Cr.

Hardhead. See DUCKS AND GEESE.

Hare's-foot Fern. See FERNS.

Hare-wallaby, the popular name for three species of the genus *Lagorchestes* and family Macropodidae. All the species are confined to the Australian mainland. The Common Hare-wallaby (*L. leporoides*), of the interior of New South Wales and South Australia, is hare-like in size and in the general appearance of its fur, but resembles its allies the wallabies in the special modification of its limbs. It is fairly abundant in open country in the interior. In Western Australia its place is taken by the Rufous Hare-wallaby (*L. hirsutus*), distinguished by the presence of a rich rufous patch on the rump; and in the north of Australia generally, as well as in certain of the islands off the north-western coast, there occurs a third species, the Spectacled Hare-wallaby (*L. conspicillatus*), so named on account of a band of chestnut surrounding the eye. See MARSUPIALS. W.A.H.

Hargrave, JOHN FLETCHER (1815-1885), born at Greenwich near London on 28 December 1815, and educated at the university of London (where he became a friend of Dr. Woolley) and at Trinity College, Cambridge (B.A., 1837; M.A., 1840), was called to the bar from Lincoln's Inn in 1841 and immediately began to establish a reputation as writer of textbooks. He practised at the equity bar until 1856, in which year he migrated to Australia, and soon afterwards was made a district court judge. In February 1859 he resigned this position and entered politics, becoming solicitor-general in the second Cowper ministry on 21 February 1859, retaining the post in the Forster ministry of 1859-60, taking the attorney-generalship in the Robertson-Cowper ministries of 1860-3, and towards the close of that period reverting to his

old post of solicitor-general, which he also held in the fourth (1865) Cowper ministry. On 22 June 1865 he left politics to become a puisne judge of the New South Wales supreme court, and held that position until 11 October 1881, when he retired on a pension. During his political career he was at first a member of the assembly, representing East Camden in March and April 1859, and Illawarra from June to October; on 10 October 1859 he was nominated to the legislative council, and renominated in June 1861, when the first appointment terminated. He died on 23 February 1885. His work in the council included the carrying through of several important pieces of legislation—an insolvency act, among others, and an act for abolishing state aid to religion; his assumption of the attorney-generalship was intended to give him greater authority while piloting John Robertson's land bills through the council. From 1858 to 1865 he was reader in general jurisprudence at the university of Sydney. While on the bench of the supreme court he was primary judge in equity and (later) first judge of the divorce court.

Hargrave, LAWRENCE (1850-1915), born in England in 1850, was the son of J. F. Hargrave mentioned above. When his father migrated to Australia in 1856, Lawrence was left in England to continue his education, but came out in 1866, was apprenticed to an engineering firm, and was afterwards an assistant at the Sydney observatory. During his work there his attention was directed to the study of air currents; this led him to consider the problems connected with flight, especially human flight, and the solution of these problems became his life's work. In 1884-92 he experimented with monoplane models constructed of a framework of light wood and tissue-paper, the earliest of which were propelled by means of flapping wings, the later ones by a screw. The motive power was, first, clockwork, then rubber-bands in tension, then compressed air, and lastly steam. With these models flights of between 300 and 400 feet were repeatedly made in a horizontal course, but they could neither rise from the ground nor steer to right or left; and the most important result of these achievements was probably the world-wide stimulus they gave to the study of aerodynamics. The compressed air and steam engines designed to drive the models were extremely simple and light, yet marvels of ingenuity. These alone were sufficient to stamp Hargrave as an exceptionally resourceful engineer.

Prominent amongst his discoveries at this time was that of the rotary aeroplane-engine, made in 1889. To quote his own words, 'The idea was conceived that a three-cylinder screw engine could be made by turning the boss of the propeller into an engine, thus allowing the cylinders to revolve on the crank-shaft, the shaft and crank-pin being stationary and the thrust coming direct on the valve-face.' His engine designed on these lines weighed only 7½ ounces, and made 456 revolutions per minute. Rotary engines based on this design have proved peculiarly adapted to aeroplane work, for a fly-wheel effect is obtained which increases the smoothness of running. The celebrated French Gnome, the Clerget and Le Rhone are modern engines constructed on this principle.

The two halves of the body-plane of Hargrave's monoplanes were composed of flat surfaces, continuous in the early models, but set at a dihedral angle in the later. In 1892 he began to experiment with curved surfaces. The increased lift obtained with these opened up a new and larger field for research, and resulted in the production of cellular kites, upon which Hargrave's place in aeronautical history chiefly rests. The most efficient kite constructed in 1893 had two rectangular cells, separated at a distance of 21.25 inches fore and aft by a wooden rod. It was experimentally proved that such a kite, with the upper and lower surfaces curved (convex above and concave below), exerted twice the lift of one in which they were flat. In 1894 by means of four kites weighing 34lb. 13oz., he succeeded in raising a weight of 208lb. a distance of 16 feet from the ground in a 21-miles-per-hour wind. The kites employed for this experiment were, owing to the difficulty then experienced of making the curves sufficiently rigid, composed entirely of plane surfaces, otherwise a much greater lift would have been obtained. Much time was now devoted to designing kites that would soar in a horizontal wind, and in 1897 Hargrave succeeded in flying a kite which soared 20° to windward of the zenith in a 12- or 14-miles-per-hour breeze. Hargrave's kites proved to be of epoch-making importance. They possessed far greater lift and stability than any apparatus previously discovered, and paved the way for the successful heavier-than-air flying machine. The first aeroplane that ever flew publicly, that of Santos-Dumont in France in 1906, was simply an arrangement of the Hargrave box-kite. The original models of his monoplanes, and one box kite, are now in the Sydney technological museum; all the other inventions, including the other box kites, are in the Munich museum in Germany.

The results of Hargrave's experiments were published in the *Proceedings* of the Royal Society of New South Wales as soon as they were made. He resolutely refused to patent any of his inventions, but devoted his life to the study of aeronautics for pure love of science and the progress of civilization. Towards the end of his life he took up the study of early Australian exploration, and made public some deductions from personal observation that failed to secure approval from more expert historians. It was, unfortunately, through these published views that many Australians knew him, and his real contributions to science—which were of very great value, and brought him the admiration and the thanks of the greatest pioneer aviators—remained obscure outside scientific circles. He died at Sydney on 6 July 1915.

See AVIATION, plates vii and viii and T. C. Roughley's *Lawrence Hargrave, Australia's Pioneer in Aviation,* (in *Technical Gazette of N.S.W.,* 1923-4). T.C.R.

Hargraves, EDWARD HAMMOND (1816-1891), born at Gosport in England on 7 October 1816 and privately educated at Brighton and Lewes, entered the merchant service in 1830, reached Port Jackson in 1832 and, after a few months on a station, joined the crew of a French fishing schooner to get bêche-de-mer and tortoise-shell in Torres Straits. All but seven of the crew died of typhus fever at Batavia; Hargraves, taken back to England, returned to Australia in 1834 and for the next 14 years followed pastoral pursuits, traversing a good deal of the western foothill district of New South Wales, holding a station on the Manning, and making his home at first in Illawarra (1836-41) and then at Gosford on Brisbane Water (1841-9). On 6 July 1849, disgusted with poor returns from cattle-

sales, he sailed for the Californian gold-diggings, where he had fair success at the Wood's Creek field in the Stanislaus valley. While there he repeatedly assured friends that he knew places in New South Wales of exactly the same kind, where gold must be found sooner or later; and as soon as he had gained enough to recompense him for the double trans-Pacific journey he went back to New South Wales, reached Sydney on 7 January 1851, made up-country (without even going home to Gosford) for the rough valleys beyond Bathurst that he had in mind, picked up at Guyong a young bushman, John Lister, and with him on 12 February washed the first pan of gold-bearing gravel at the junction of the Summerhill and Lewis Ponds creeks. Confirming this discovery by further samplings of creek-gravel over an area of 70 by 40 miles in the Macquarie valley—during which James Tom acted as his and Lister's guide—he hastened back to Sydney to bargain with the authorities for £500 before he disclosed the auriferous localities. Deas Thomson, however, insisted that he must trust the government's generosity. He agreed to do so, named the localities, and within three months 400 diggers were camped at Ophir (the scene of the first discovery), while others were prospecting the neighbouring valleys. The £500 was duly paid over to him in June.

The story of the later discoveries is told under GOLD, DISCOVERY OF. Hargraves's part in it was not great. He was appointed commissioner of crown lands, and in October 1853 was granted a sum of £10,000 by the New South Wales legislature; the Victorian legislature—partly because Victoria was in February 1851 part of New South Wales, partly because it was his discovery that stimulated the search for gold in the Port Phillip district—voted him £5000 but in the end paid him only £2381. In 1854 he visited England, was presented to Queen Victoria, and in the next year published *Australia and Its Goldfields*. In 1862 he visited Western Australia at the request of the government, but after six months' labour failed to find any gold, and reported that the colony was non-auriferous but rich in copper, lead and iron. In those days, it must be remembered, the colony was a mere strip on the south-western corner of the continent, and Hargraves never had a chance of investigating the inland plains where great deposits of gold have since been found. In 1864 he was equally unsuccessful in Tasmania. The rest of his life was uneventful. In 1877 the New South Wales legislature added to its previous grants an annuity of £250 for life. He died at Forest Lodge, a Sydney suburb, on 29 October 1891.

His claim to be the first discoverer of gold in Australia has been frequently contested from two standpoints. It is contended—quite accurately—that several predecessors had found gold in New South Wales, notably Strzelecki (q.v.) in 1839 and W. B. Clarke (q.v.) in 1841-2. In those days the colony was still a convict settlement, and knowledge of the discoveries was carefully suppressed by high officials; there is no reason to suppose that Hargraves knew of them. It does not in the least detract from his merit to admit that, scientifically speaking, he had predecessors, nor from theirs to admit that, partly because there was no further need for suppression, he was the first to make a practically useful discovery. On the other hand, representatives of Lister have contended that he took Hargraves to the fateful spot, and the Toms claimed that they were the first to get gold in payable quantities. Hargraves from the first denied both these allegations, and it is impossible to procure any other first-hand evidence on the subject. It is, however, indisputable that Hargraves drew conclusions from his own experience, returned to Australia from California specially in order to look for gold where he expected to find it, found it in the district—if not in the exact spot—where he intended to look for it, taught Lister and the Toms how to wash gravel, and was the effective cause of the subsequent goldrush. ('Had I known' said Charles Blakefield to W. B. Clarke in 1852, 'that the whole science of gold-washing lay in the shaking of a tin dish,' the rush would have occurred in 1843.) There is no need to claim anything more for him; but that claim is enough for his enduring fame.

Harlequin Fish. See ROCK COD.

Harpullia, a small genus of the family Sapindaceae, with several species in tropical Asia and Madagascar, and 5 endemic in Australia—mostly in the eastern States. *H. pendula* (Tulipwood) is a medium-sized tree of the coastal brush forests ranging from northern New South Wales to Queensland. It has a handsome timber, nicely marked and shading from yellow to black, which has been used in making billiard tables and other furniture. It is tough and durable, resembling olive-wood, and is said to be our best timber for lithographic scrapers.

Harpur, CHARLES (1813-1868), born at Windsor on the Hawkesbury on 23 January 1813, spent most of his early years in the bush, but was for a short time accountant in the Sydney post-office and so had an opportunity of meeting the few literary men of those days. In 1843 he took up farming on the Hunter River, and from 1850 onwards owned a small sheep-station; but by 1858 he was glad to accept from Sir John Robertson the post of gold commissioner at Araluen. Concurrently with this work he farmed land at Eurobodalla, but unsuccessfully; in 1866 his commissionership was abolished, in 1867 he lost his second son by a gun-accident, and during the winter of that year his farm was almost destroyed by floods. Sinking beneath these misfortunes, he died on 10 June 1868.

Harpur was the first Australian-born poet to deserve more than the meagrest of mentions. A slow writer, and dominated (like all his contemporaries) by the traditional phraseology of English verse, he wrote little that is worth study except in blank verse; but his 'Creek of the Four Graves' will always be remembered as the first good verse directly inspired by and depicting life in the Australian bush. In 1845 he published a small book of sonnets, in 1853 a play and a few poems, and two more volumes in 1862 and 1865; but his verse was first collected and given an attractive form in 1883. Probably the best eulogy of him lies in the statement that he inspired Kendall both to a closer study of bush life and to a fine threnody.

Harrier. See HAWKS.

Harris, JOHN (1754-1838), born at Magherafelt in county Londonderry, Ireland, in 1754 and trained for the medical profession at the university at Edinburgh, served as a surgeon in the navy for ten years in East Indian waters, and in 1789 was appointed surgeon mate of the New South Wales Corps. The original corps surgeon, James Maccauley, resigned his post before the corps left England, and Harris was practically surgeon from the time of his embarkation for

the colony, although he did not obtain the substantive rank until 1792. He reached New South Wales in the *Surprize* on 26 June 1790, and was posted at Parramatta: on 1 April 1793 Grose gave him 100 acres at Parramatta, and on the 18th he bought from James Ruse (q.v.) the farm afterwards called Experiment Farm. The Parramatta grant being needed for public purposes, a fresh grant of 110 acres at Rose Hill was made to him on 20 February 1794, and this, with the adjoining Ruse grant, became the estate since known as Harris Park. In 1800 he was made a magistrate, and in 1802 succeeded William Balmain as 'naval officer'—i.e. officer controlling the port of Sydney: in the same year he was put in charge of the police, and King reported that he was performing all his duties 'to the evident public benefit and conspicuous general good of His Majesty's service without neglecting an hour's duty as surgeon of the corps.' King might have added exploration to his other tasks, for in 1801 Harris accompanied Grant in the *Lady Nelson* to the Hunter River and took part in the exploration of its valley far beyond Maitland. He earned, however, as port officer a good deal of unpopularity by aiding King to suppress the liquor traffic, and in October 1802 was court-martialled on charges brought against him by his commanding officer in the corps (Paterson), but was unanimously and honourably acquitted. In 1803 King, knowing that he had occasionally acted as deputy judge advocate, made him prosecutor at the trial of Captain Kemp: Johnston, who was commanding during Paterson's illness, promptly put Harris under arrest again, and a long dispute followed. Meanwhile King had reinstated Harris in the positions (magistrate, naval officer, and head of the police) from which his first court-martialling had automatically removed him, but Harris accepted the magistracy only: still, in 1804 King again eulogized his services, particularly mentioning his share in the building of the cutter *Integrity* (see SHIPBUILDING), and in March of that year persuaded him to act as naval officer during the absence of the new appointee. Bligh in April 1807 dismissed him from that post and even from the magistracy, probably for the mere reason that he was an officer of the hated corps: but Harris, in letters to his old friend King and Mrs. King that throw a great deal of light on Bligh's unpopularity (they are given in *H.R.N.S.W.*, vi. 336-49), says that he resigned the post of naval officer and Bligh, 'to be revenged,' dismissed him from the magistracy.

On 27 January 1808, immediately after the mutiny against Bligh, Johnston reinstated Harris as a magistrate, but in April, finding that he and Macarthur were at odds, dismissed him again. After a curiously acrimonious correspondence in which Harris hinted that he knew a good deal more than Johnston about the causes of the mutiny, he was sent to England as a witness for the mutineers: but it is noteworthy that a petition of 30 June to Colonel Paterson, signed by anti-Johnston settlers, specifically expresses confidence in Harris and asks for his retention in office. Paterson accordingly objected to letting Harris go, but Johnston insisted, and he left Sydney in the *Admiral Gambier* along with Johnston himself, Macarthur, and Dr. Jamison (a most incongruous collection) on 28 March 1809. On the way home the vessel put in at Cape Town, and Harris made the acquaintance of the Macquaries, who were on their way out in the *Hindostan*: the impression he made on Mrs. Macquarie was not favourable, and probably accounts for certain occurrences in later years.

While in England Harris retired from the corps, and in 1813 petitioned the colonial office for leave to return to New South Wales as a free settler. Reaching Sydney again early in 1814, he settled down as a landowner and took very little interest in politics thenceforth, except in so far as he sided with Ellis Bent and his friends against Macquarie's encouragement of emancipists. In 1817 he helped to found the Bank of New South Wales, of which he was one of the first directors. In 1818, at the age of 64, he volunteered his services as surgeon for the famous and arduous expedition in which Oxley discovered the Liverpool Plains and Port Macquarie. In June 1819 Macquarie made him once more a magistrate, but in the following February charged him with grave disrespect. As magistrate he sat with Judge Field in the supreme court. In Brisbane's time he was involved in that governor's disputes with Samuel Marsden, but merely as an over-severe magistrate. Darling he supported against Wentworth, as became a large landed proprietor. He died on 27 April 1838.

Harris was, as King found, versatile and hard-working: he was also a man of very wide interests. He managed vigorously a large estate—besides the Harris Park land already mentioned King gave him 750 acres, and by 1807 Johnston, Marsden, and Harris were the three biggest landowners in the colony after Macarthur. Macquarie, too, during that moment of favour in 1819 granted him another 1100 acres near Bathurst. He was especially proud of his herd of spotted deer (chital) from southern India, which was unfortunately dispersed during his absence in England in 1809-12. In the *Lady Nelson* (1801) trip he was particularly active and adventurous. He had an affection for the name 'John;' he named his Parramatta estate 'Shane's Park' because Shane is the Celtic form of John, and in his will ordered that it should descend only to heirs of that name. His Sydney house—Ultimo House—got its name not (as many people have believed from his day until now) because it was, when built, the last house in Sydney, but because an official at one of his courts martial used the word *ultimo* ignorantly for *proximo* (according to Mrs. Macquarie, for 'instant'): this tickled Harris's fancy, and he wrote a satirical poem on the mistake and afterwards named the house 'Ultimo Place.'

Harrison, JAMES (1815-1893), born at Renton in Dumbartonshire, Scotland, in 1815 and apprenticed as a boy to a printer in Glasgow, was in 1837 sent out to Sydney from London in charge of some printing material consigned to James Tegg, a Sydney bookseller, for use in producing the *Literary News*—a magazine edited by William à Beckett (q.v.). To this magazine Harrison contributed, working also on the staffs of the *Monitor* and *Sydney Herald*. In 1839 he moved to Melbourne and joined Fawkner on the *Port Phillip Patriot*, but the next year was sent to Geelong to edit another of Fawkner's papers, the weekly *Geelong Advertiser*, the first issue of which was published on 21 November 1840. In 1842 Harrison bought Fawkner out, and in the following year began to issue the paper twice (and not long afterwards three times) a week. In 1851 he also published a few numbers of a literary quarterly, *The Australian*. During his ownership of the *Advertiser* he represented Geelong in the Victorian legislature from 1856 to 1861. About 1852 he began to study closely the

formation of ice by the evaporation of ether, and in 1856 and 1857 patented his process, which T. B. Lightfoot describes as 'much more complete and practical' than the contemporary and similar American process. At Rodey Point on the Barwon he built the first ice factory in Australia, but found that ice-making machinery on a commercial scale was unobtainable in Melbourne or Sydney, and went to London to exploit his invention. Scientific and business men in several European capitals approved of his patents, but were not prepared to pay his price for them: he therefore concentrated on the construction of a large machine, which he brought back to Victoria in 1859 and—finding that Geelong's demand for ice was insignificant—installed it at a factory in Franklin-street, Melbourne, producing with it up to 10 tons a day. Commercially, however, the enterprise was a failure, and in 1861 Harrison was made bankrupt and the *Advertiser* was sold to Douglass and De Little, who promptly re-installed Harrison as editor. Tiring of the subordinate position, he in 1865 started the *Geelong Register*, but, lacking capital to maintain it, in 1866 turned it into a company which was soon bought out by Graham Berry (q.v.), Harrison going back to Melbourne, where he became sub-editor of the *Age*. In 1873 he became notable as the inventor of a new process of freezing carcases for export. The American process then in vogue merely froze the surface of the flesh—which sufficed for the short voyage between the United States and England, but allowed decomposition to occur internally during a long voyage, so that Australian meat after thawing rapidly developed putrescence. Harrison's process froze the meat right through, so that all natural decay was suspended no matter how long the voyage lasted, and, after a slow thawing (20 hours at a temperature of 63°) the body fluids re-appeared as fresh as when they had been frozen. For this he was awarded a gold medal at the Melbourne exhibition of 1873, and, on proving that the cost of freezing and freightage would not exceed 7s. per ton, was given £2500 to take 25 tons of frozen beef to London. Unluckily the process that suited mutton perfectly would not do with beef. Twenty years later it was discovered that the small blood-vessels in beef carcases burst when frozen, and so, when thawed out again, damage the flesh they are embedded in. Beef must be chilled, not frozen; and Harrison's cargo was found unusable when thawed out in London. Of his later life little is known. He was away from Australia until 1892, but in that year returned to Geelong, settled down at Point Henry, and resumed intermittently his connection with the *Age*. He died on 3 September 1893.

For details of Harrison's carcase-freezing process see *Report on Meat Freezing Processes*, Victorian Agricultural Department, 1873. A.W.G.

Hart, JOHN (1809-1873), born in England in 1809, went to sea while still a boy and in 1831 became master of a sealing schooner hunting in Bass Strait and along the southern coast of Australia. (His first voyage as master, for instance, was from Launceston in Tasmania to Portland in Victoria, thence to Guichen Bay in South Australia, thence to Nepean Bay in Kangaroo Island; its result was 580 sealskins, and 12,000 wallaby-skins bought from the islanders.) In 1836 he left sealing for more general trade, taking from Launceston the first live stock ever landed in South Australia. Returning to London, he bought the *Isabella* for this trade, and brought her out, but in 1837 she was wrecked at Portland Bay. He next experimented with 'overlanding,' but about the end of 1838 established the headquarters of a whale-fishery at Encounter Bay. He seems to have been an experienced and reputable seaman, for his services were always in demand, even after his vessel had been wrecked.

In 1846 he gave up the sea and devoted himself to flour-milling at Adelaide, making one of the best brands of flour known in Australia. Indignant at the harsh terms imposed by Governor Robe (q.v) on intending settlers, he entered politics, succeeded in getting the grievance remedied, became a member of the council of 1851, and when responsible government was introduced was elected to the legislative assembly as member for Port Adelaide in 1857. He was treasurer in two of the ephemeral ministries of 1857-8, and chief secretary in four others in 1863-5; then he was thrice premier (October 1865 to March 1866; September-October 1868; May 1870 to November 1871). Although the conditions of the colony made tenures of office almost spasmodic, he managed to do effective work. During his last premiership he carried through the construction of the overland telegraph line to the Northern Territory, a region in which he was much interested; and his financial measures were always sound and much approved of, his experimental issue of five per cent bonds in 1871 being an especially notable success. He was the first advocate of consolidating the colony's public debt. On 28 January 1873 he died suddenly at Adelaide while addressing a meeting of the Mercantile Marine Insurance Company, which he had helped to found in 1869. (C.M.G., 1870.)

Hartog, Dirck. See AUSTRALIA, DISCOVERY OF.

Harvest-men (harvest-spiders), the vernacular name of arachnids of the order Phalangida, often called Opiliones. They are easily distinguished from spiders by the fact that the cephalothorax and abdomen are not separated by a constriction but fused together; they are sometimes mistaken for mites, but may be distinguished from them by their segmented abdomens. The legs, too, are usually long and slender, and this serves as an additional aid to identification. The upper part of the cephalothorax often bears a grooved and spiny turret, on the sides of which are placed a pair of simple eyes; on the lower surface there is situated, as in spiders, a 'sternum,' while a labium is usually present. The form of the sternum is highly important for purposes of classification. The cephalothorax is always unsegmented, the abdomen always segmented to a greater or less degree, the number of segments varying as the fusion of the cephalothorax with the abdomen is more or less complete. Hansen and Sörensen give the normal number of segments as 10, but this is subject to variation in different species.

Harvest-men, like other members of the Arachnida, have six pairs of appendages. The first pair, the three-jointed chelicerae, are very long in some forms, and usually terminate in a pair of pincers (chelae). The second pair, the pedipalpi, are non-chelate and have six joints, which correspond to similar segments in the legs. The legs, which like those of spiders have seven joints (the seventh being the metatarsus), are usually long and brittle. Silk-spinning glands are absent, and harvest-men are therefore unable to construct nests.

The order is subdivided into three sub-orders: (1) Cyphophthalmi, (2) Mecostethi, (3) Plagio-

stethi. The first sub-order is not represented in Australia. The second is characterized by its long and narrow sternum. Each of the tarsi of the first two pairs of legs is provided with only a single claw, but the last two pairs have two claws each. The great majority of our harvestmen are included in this sub-order, which is further divided into six families, the largest being the Triaenonychidae; a representative of this family is *Triaenonyx rapax*, which occurs commonly under logs in the dense brushes of the northern rivers of New South Wales. Members of the third sub-order, the Plagiostethi (sometimes termed Palpatores), are distinguished by having the sternum of the cephalothorax short and transverse, while the tarsi of the legs have only a single claw. Only one family of this sub-order appears to be represented in Australia, the Phalangiidae, of which *Macropsalis serritarsus*, known from the Jenolan caves, may be regarded as typical.

See Sörensen in Koch's *Die Arachniden Australiens* (Suppl. 1884-89); Roewer in *Archiv. Naturgeschicte* (1915, 80A, Heft 12), and in *Ark. Zool. Stockholm* (1920, Band 13, No. 18); Pocock in *Proceedings* of the Zoological Society of London (1902, vol. ii), and Hansen & Sörensen's *Two Orders of Arachnida, Opiliones & Ricinulei* (1904).

A. M.

Hassall, Rowland (1768-1820), was one of the laymen in the party of missionaries who were sent by the London Missionary Society in 1796 to Tahiti, and who in 1798 were forced to abandon their mission and take refuge in New South Wales. Hassall on arrival in Sydney at once made friends with Marsden, and stayed with him for a few weeks: then Hunter granted him 100 acres at Dundas, and he settled down to farm them, preaching to scanty congregations alternately at Toongabbie and Kissing Point. Judging by his extant correspondence, he was ill-educated: this defect, and his lack of orders, prevented him from being taken on the staff of chaplains, and in September 1800 King, acting on a recommendation from Hunter, appointed him caretaker of the Parramatta granary and storekeeper at Toongabbie. This work, however—entailing constant watchfulness against the frauds and forgeries of unscrupulous men, and enough business ability to cope with their cunning—was far beyond Hassall's powers, and in September 1802 he was dismissed. That nothing more than unsuitability was charged against him is clear from the fact that King, when he left the colony, gave Hassall charge of his own herd of cattle; and Dr. John Harris in 1807 praised Hassall's assiduous care and mentioned that he was 'in the background' with Governor Bligh just because he was so careful of King's interests. (He put himself on record, however, as a supporter of Bligh's when the mutinous New South Wales Corps deposed him.) In 1804-5 he was enrolled in the Parramatta company of volunteers as sergeant: at this time, King not having yet left the colony, he was looking after a flock of crossbred sheep partly owned by two other persons, and Marsden was helping him to improve the strain in his own section.

In 1814 Macquarie made him superintendent of government herds, and he seems to have held this post until his death at Parramatta on 28 August 1820.

Haswell, William Aitcheson (1854-1925), born at Edinburgh on 5 August 1854 and educated at the Edinburgh Institution and the university of Edinburgh (B.Sc., 1878; D.Sc., 1897)—where he studied under T. H. Huxley and won the Baxter scholarship—in 1879 migrated to Brisbane and in 1880 became curator of the museum there; in 1882 he was appointed lecturer in zoology and demonstrator of histology at the university of Sydney. In 1890 he was made Challis professor of biology, and when in 1915 that chair was divided became Challis professor of zoology; on his resignation in 1918 he was made professor emeritus. In learned circles in Germany he, Anderson Stuart, and Edgeworth David were reckoned the three Sydney professors who had 'achieved something for science and made the Australian universities notable in the learned world' (Schacht). In 1892-3 he was president of the Linnean Society of New South Wales; in 1897 he was made a fellow of the Royal Society; from 1912 to 1917 he sat on the university senate. Besides a large number of zoological papers and pamphlets, he published in 1898 a *Text-Book of Zoology* (written in collaboration with Professor T. J. Parker) and in 1899 a *Manual of Zoology*. The *Text-Book*, which was republished in 1910 and 1921—and had by that time become almost wholly Haswell's work—is recognized all over the world as the standard English textbook on the subject. His special studies were concerned with the invertebrates, and at the time of his death he was engaged in investigating a group of flat-worms (q.v.), the Temnocephaloidea, which afford important evidence of a former land-connection between Australia and South America by way of the Antarctic continent. He died at Sydney on 24 January 1925.

Hawks, birds, usually of moderate or large size, with strong hooked beaks and stout sharp claws, belonging to the order Accipitriformes. Twenty-five species occur in Australia, including

Wedge-tailed Eagle.

representatives of the groups known as eagles, harriers, goshawks, kites, falcons, kestrels, and ospreys. There are also several peculiarly Australian species, whose relationships and proper position in the order are not yet determined.

The best-known of Australian hawks is the Wedge-tailed Eagle or Eagle-hawk (*Uroaëtus audax*), found throughout the continent and Tasmania; it is one of the largest eagles in the world, sometimes having a 10-foot spread of wing. Its coloration varies from rufous-brown to black. Its natural food is wallabies, young kangaroos, and large birds such as bustards—also carrion; but it has taken readily to rabbits since they were introduced, and occasionally kills lambs—for which reason enormous numbers have been destroyed by pastoralists, advantage being taken of the bird's carrion-eating propensities to poison carcases. Many pastoralists, however, maintain that this is a mistaken policy, regarding the few lambs taken as amply compensated for by the eagle-hawk's destruction of rabbits and of carcases in which blowflies would breed. It is to be hoped that this view will become general before such a fine bird is exterminated.

Four other Australian hawks are classed as eagles, the finest being the White-breasted Sea Eagle (*Haliaëtus leucogaster*) (a near relative of the bald eagle of the United States) which is found all round our coasts. This species builds immense nests of sticks, either in trees or on rocky islands, almost always near the sea, the structure being added to year by year; such nests were seen by several early explorers, probably first by Vlamingh in 1697. Flinders remarks that 'if the magnitude of the constructor be proportionate to the size of the nest, *Terra Australis* must be inhabited by a species of bird little inferior to the condor of the Andes.'

The commonest of the Australian eagles is the Whistling Eagle (*Haliastur sphenurus*), which occurs wherever there is water in the neighbourhood. It is a valuable scavenger, and also destroys numbers of large caterpillars, of which it appears to be specially fond. The White-headed Sea Eagle (*Haliastur indus*) is the bird known

White Goshawk.

in India as the Brahminy kite. It occurs all round our northern coasts wherever there are mangroves. The Little Eagle (*Hieraëtus pennatus*), a rare species, is chiefly found far inland.

Two harriers occur in Australia, the Spotted Harrier (*Circus assimilis*) chiefly found inland, and the Swamp-hawk (*Circus approximans*), plentiful wherever there are swamps in the coastal districts of southern Australia and Tasmania.

Australia has also two goshawks, one of which is remarkable because it exists in two distinct colour-forms, gray and white. The latter form is more widespread, being found in Tasmania and north-western Australia, where the gray bird is unknown. In northern and eastern Australia, where the two forms occur together, they frequently interbreed; but some authorities still consider them distinct species, calling the gray bird *Astur clarus* and the white bird *Astur novaehollandiae*. The Collared Sparrow-hawk (*Accipiter torquatus*) the only true sparrow-hawk in Australia, is closely related to the sparrow-hawk of England; but the name 'sparrow-hawk' is often applied to the kestrel, a very distinct bird.

Of kites Australia possesses four species; the Black Kite (*Milvus migrans*), whose range extends to southern Europe, the Square-tailed Kite (*Lophoictinia isura*), peculiar to Australia, and two small blue-gray birds—the Black-shouldered Kite (*Elanus axillaris*) and the Letter-winged Kite (*Elanus scriptus*), both chiefly confined to the inland districts.

The so-called Red Goshawk (*Erythrotriorchis radiatus*) of northern Australia is really related to the buzzards of other countries; but the

Crested Hawk.

affinities of the fine Black-breasted Buzzard (*Hamirostra melanosterna*), the most distinct of the endemic species, are still undetermined. The curious Crested Hawk (*Baza subcristata*), perhaps the handsomest Australian member of the family, inhabits tropical scrubs along the northern and eastern coasts of the continent.

Australia has four true falcons (*Falco*), of which the Black-cheeked Falcon (*Falco peregrinus*) is perhaps the finest. This bird has an almost world-wide range, being known in England as the peregrine falcon and in the United States as the duck-hawk. The Little Falcon (*Falco longipennis*) is the commonest and perhaps the boldest of our falcons, capturing birds often much larger than itself.

The Brown Hawk (*Ieracidea berigora*), like the gray (or white) goshawk, exhibits dimorphism, though some authorities regard the two forms as distinct species. One form is very dark brown, almost black below; the other is sandy-brown, with dark streaks on each feather. In some localities one form only occurs, in others both are found together, and intermediates are not uncommon. The brown hawk is distinctly intermediate between the rapidly flying true falcons and the constantly hovering kestrels. It frequently hovers like the latter, but is not nearly so clever as its smaller relative.

The Australian representative of the kestrels is the Nankeen Kestrel (*Cerchneis cenchroides*), the commonest of all hawks throughout Australia and Tasmania. It is often called 'sparrow-hawk;' but this name gives an erroneous idea of its habits, and belongs to a very different species. Its food consists almost entirely of mice, lizards and large insects; while watching for them, it hangs poised and stationary in the air, with rapidly beating wings. In power of hovering it is surpassed only by the tiny humming-birds of America.

Finally we must mention the Osprey or Fish-hawk (*Pandion haliaëtus*), common on most parts of the Australian coast, which is found almost throughout the world. W.B.A.

Hay, Sir John (1816-1892), born at Little Ythsie in Aberdeenshire and educated at the university of Aberdeen (M.A., 1834), studied for the Scottish bar in Edinburgh, but in 1838 migrated to New South Wales and took up land for pastoral purposes at Welaregang on the upper Murray. He was already interested in politics, and in 1839 spoke on freetrade at a meeting in Albury; but his first active appearance in this sphere was in April 1856, when the Murrumbidgee constituency elected him unopposed as its representative to the new assembly. Carrying in September a vote of want of confidence in the Cowper-Martin ministry, he became secretary for lands in Parker's ministry, which lasted until 7 September 1857. He represented successively the Murray (1858-64) and Central Cumberland (1864-7), spending the first few years in opposition, and being chosen as speaker on 14 October 1862; this post he resigned for reasons of health on 21 October 1865. In 1867 he was nominated to the council, and on 8 July 1873 became president of that body, a position which he held until his death on 20 January 1892.

Hay was a consistent opponent of the Robertson land-policy of 'free selection before survey,' and in 1860 carried an amendment deleting it from the crown lands alienation bill; but the ensuing dissolution resulted in Robertson's return with an enlarged majority. Hay also repeatedly advocated a customs union with Victoria, so as to ensure the abolition of customs houses along the Murray. (K.C.M.G., 1878.)

The above-mentioned Sir John Hay must not be confused with Sir John Hay (1841-1909), a nephew of David Berry, who, inheriting the Berry estate in 1889, sent to the university of St. Andrews in Scotland Berry's bequest of £25,000 and was made LL.D. therefor. In 1907 he was made commissioner from New South Wales to the Anglo-French exhibition of that year, and was knighted for his services.

Hayes, Sir Henry Browne (1762-1832), born at Cork in Ireland in 1762, and admitted freeman of that city on 12 November 1782, was for the next 15 years a prominent figure in Cork society: in 1790 he was sheriff, and a few years later was commissioned captain in the South Cork militia. In 1797 he abducted an heiress, but let her return to her home unharmed after a sham marriage. He was promptly outlawed and had a reward of £1000 offered for his apprehension, yet after a short interval he was again living peacefully in Cork, whereas the heiress was forced by public opinion to retire to England. However, in 1800 he offered —possibly thinking that his local popularity would secure an acquittal—to stand his trial at Cork, and in April 1801 he was found guilty, mainly owing to the extraordinary ability and tact of J. P. Curran, counsel for the prosecution. In August Hayes was condemned to death, but in September the sentence was commuted to transportation for life. Put aboard the convict transport *Atlas,* which sailed from Cork on 28 November 1801, he paid the master several hundred guineas to obtain exceptional favours, and much annoyed the free officials who were travelling in the same vessel by monopolizing most of the free space and nearly all the available comforts. Among these officials was Thomas Jamison, on his way to take up the surgeon-generalship of the colony; he left the vessel in anger at Rio de Janeiro, took passage in the *Hercules,* and reached Sydney ten days before Hayes, against whom he at once instituted an action for 'threatening and improper conduct.' Hayes was sentenced by the magistrates to six months' imprisonment, but after serving five-sixths of the sentence was given a ticket of leave and sent to Parramatta, under threat of exile to Norfolk Island if he dared return to Sydney. Unused to any compulsion that could not be mitigated or removed by his wealth, Hayes complained indignantly to the authorities in London, and set himself to attack and annoy Governor King. Having in some way (he himself calls it 'being liberated by a respectful bench of magistrates') been enabled to return to Sydney, he applied for leave to hold a masonic lodge (see Freemasonry); leave being refused, he held it all the same, and in May 1803 was ordered to hard labour at the settlement then proposed to be made in Tasmania. This, too, he managed to evade, for on 22 August he bought two farms near South Head —the well-known Vaucluse estate which was in later years the home of William Charles Wentworth. Here he lived for some years, though—being still a convict—he could not obtain a legal title to the property. King, who firmly believed that Hayes was concerned in the insurrection of March 1804, suffered greatly from his bitter personal attacks both in the colony and by letter to the colonial office, and in July 1805 obtained from five magistrates (Johnston, Marsden, Harris, Jamison, and Atkins) an opinion that his exile would be the best means of maintaining peace at Sydney: Hayes was therefore sent to Norfolk Island, but after a month there brought back to Sydney for exile to Tasmania. Again his luck held: storms delayed the vessel bound for Tasmania, and before the fresh sentence could be carried out Bligh had succeeded King as governor.

Under Bligh Hayes calmed down and spent his time mainly at Vaucluse. But the mutiny against Bligh involved Hayes also; having openly sympathized with the deposed governor, he was sent by Johnston in March 1808 to the dreaded Newcastle coal-mines. Eight months later Foveaux allowed him to return to Vaucluse;

but in May 1809 he was again sent to the coal-mines, and on this occasion fell foul of Lieutenant Lawson, who charged him with 'bringing the existing government into ridicule and contempt.' It is not clear how Hayes was released on this second occasion, but in March 1810 he was back at Vaucluse memorializing Macquarie about Lawson's ill-treatment of him. His support of Bligh now stood him in good stead. Bligh had in April 1809 written out a full pardon for him, but could not make it effective because the mutineers had the colony's great seal. The colonial office, therefore, in August 1811 notified Macquarie that Bligh's intentions should be carried into effect if Hayes had been behaving himself properly. The despatch was slow in coming, but in November 1812 Macquarie issued the pardon, and on 4 December Hayes left the colony in the *Isabella*, with Joseph Holt (q.v.) as a fellow-passenger. The ship was wrecked on the Falkland Islands, and (according to the journal of one of her officers) Hayes with a few accomplices endangered the lives of the other passengers by stealing the small boat and making for shore. After many adventures all were rescued and Hayes returned to Ireland in 1814. The rest of his life was spent in retirement at Grantham Hill near Cork, where he died in May 1832. (Kt. Bach., 1790.)

The story of Hayes's connection with Vaucluse House is fully told in the *Journal* of the Royal Australian Historical Society, vol. iii, pp. 507-30. It may be noted here that the best-known part of it—his attempt to banish snakes from the precincts of Vaucluse by surrounding the house with turf brought from Ireland, and therefore endowed by St. Patrick with anti-ophidian properties—is probably true. The bill of lading for the imported soil was in existence late in the last century.

Hayes, Sir John (1767-1831), born probably in Cumberland, certainly in 1767, at the age of 13 joined the Bombay marine service (midshipman, 1781; 2nd lieutenant, 1788; 1st lieutenant, 1792; commander, 1799; captain, 1802), and saw much fighting in the wars with France and Tippoo Sahib during 1781-92. In 1792, the war being over, Hayes met in Calcutta a fellow-officer, John McCluer, who in 1790 had been instructed by the Indian government to survey the Pelew group and northern New Guinea in the neighbourhood of the gulf now known by his name. McCluer was struck with the rich vegetation of the country, and especially with the frequent occurrence of the Banda nutmeg (the most valuable of Malayan spices), which at that time was believed to exist only in Banda and Amboina. On McCluer's information Hayes formed a small syndicate to fit out two vessels—the *Duke of Clarence* and the *Duchess*—to exploit the new discoveries. Starting from Calcutta on 6 February 1793, Hayes made for New Guinea direct, but was met off Timor with such strong SE. trade-winds that he determined to reach New Guinea by the long voyage round New Holland; he therefore rounded Western Australia, and on 25 April anchored in the mouth of the Derwent. Not knowing that other explorers had preceded him (Bligh and D'Entrecasteaux among them), he made careful surveys of the whole surrounding country, including Bruni Island, and scattered names profusely over his chart. It is the fact that most of these names are Cumbrian that makes Hayes's birthplace almost certain; he called the mainland 'New Cumberland,' the river 'Derwent,' the hill now known as Mount Wellington 'Skiddaw,' and so on. Few of his names are now in use, as those given by previous explorers had the priority, but it may be noted that Risdon Cove was named after the 2nd officer of the *Duke of Clarence*. Hayes took his vessels up the river beyond Mount Direction, and explored it with boats a long way above Bridgewater. On 9 June he left Storm Bay and made for New Caledonia, which he coasted within the barrier reef at least from Bourail to Gomen; he then cut across to the Louisiades, discovered (as D'Entrecasteaux had a month earlier) that they were islands, and after a vain attempt to thread the reefs immediately south of the mainland doubled back round Rossel and Woodlark islands to New Britain. Here he ran through St. George's Channel, back to the New Guinea coast, and across Geelvink Bay to Dore at its north-western corner. In this region he found the coveted nutmeg, as well as cloves and birds of paradise, and promptly annexed the north-eastern coast of New Guinea from end to end in the King's name on 25 October as the colony of New Albion. Leaving the *Duchess* at Dore Bay, he started back to India, but, reaching Batavia on 18 June, found the Bengal squadron there and was ordered to Canton. He completed this voyage after an exciting chase by a French privateer, met McCluer in Macao on a trip from the Pelews (where he had settled), and eventually reached Calcutta on 5 December. He had hoped to persuade the East India Company to accept and protect his precious New Albion, but it was at the time under pressure—after the annexations of Warren Hastings—to confine itself strictly to mercantile business, and refused to interfere, although it denied any right in the Dutch to prevent the annexation if approved of. Sir John Shore, the governor-general of India, after discussing the matter thoroughly, managed to discover 'positive orders from the Company prohibiting new settlement to the eastward,' and the annexation came to nothing; but it was not until 1828 that the Dutch formally laid claim to New Guinea (as a possession of the sultan of Tidore) and began to establish trading stations there. It may be added that the party Hayes had left behind at Dore was succoured towards the end of the year by McCluer, who had heard about them from Hayes at Macao, and was taken off by Risdon (who had succeeded Hayes in the command of the *Duke of Clarence*) in June 1795; but trading operations with the Papuans continued at least until 1801.

Hayes in May 1795 rejoined the Bombay marine service, and in 1796 entered on a period of active war-work which earned him in May 1798 a sword of honour for intrepid behaviour. In 1799 he served ashore in the campaign that ended with the capture of Seringapatam; then he was sent to the Persian Gulf, and then (1801) to the siege of Ternate, at which he commanded the assisting squadron. In 1803 he was given command of a squadron assigned to defend the Bay of Bengal, and in 1805 was made a commodore; in 1805-7 he visited England, was received with honour by the directors of the Company, and was made deputy master attendant at Calcutta with the right to succeed the holder of the senior position. To this he succeeded in 1809, and held it for the next 21 years, with two intervals during which he was again sent on active service—in the Java expedition of 1811 and the Burmese war of 1824-5. In 1830 his health gave way, and he was given an E.I.C. cruiser for a voyage to

Sydney, but on the way fell so seriously ill that he had to be landed at Direction Island in the Cocos group, and died there on 3 July 1831. (Kt. Bach., 1826.)

The only full and accurate account of Hayes's life is contained in Ida Lee's *Commodore Sir John Hayes* (1912). He kept full journals of his voyage of 1793-4, and intended to publish them, but could not obtain the requisite financial support. They have since been lost; according to one account they were captured by a French warship and taken to Paris, but no trace of them has been found there.

Heales, RICHARD (1823-1864), son of a London ironmonger, migrated to Victoria with his father in 1842 and worked for some years as a coach-builder; interesting himself in municipal affairs, he was in 1849 elected a member of the Melbourne city council, and during the next few years took up the cause of temperance with ardour. When Victoria obtained responsible government, Heales was elected by East Bourke to the assembly and became leader of the advanced liberals; in this capacity he opposed bitterly the Nicholson land act of 1860, helped to oust that ministry, and was chosen by ballot among members of the opposition to form its successor. During his year of premiership (26 November 1860 to 14 November 1861) he accomplished little, but in 1862 succeeded as a private member in carrying through both houses a common schools act on which all subsequent educational legislation in Victoria has been based. In June 1863 he joined the McCulloch ministry as president of the board of lands and works, but after a couple of vain attempts to pass bills amending the Nicholson land act succumbed to ill-health and overwork, and died on 19 June 1864. Heales was an excellent example of what in recent times would be called a 'labour' member. Sprung from the working class, his aim throughout his political career was to improve both the working conditions and the *moral* of the artizans he knew so well; for this reason he steadily advocated free education, freer land settlement, temperance, protection of native industries, and reform of the legislative council. 'Few men' wrote H. G. Turner, 'who have had so short a public career have left more friendly memories behind them.'

Heaton, SIR JOHN HENNIKER (1848-1914), born at Rochester in Kent on 18 May 1848 and educated at King's College, London, in 1864 migrated to Australia to acquire 'colonial experience' and, after several years of pastoral life, became a journalist and married the daughter of Samuel Bennett (q.v.). He then settled down to the compilation of his *Australian Dictionary of Dates and Men of the Time,* the first serious attempt to make a 'digested summary of every branch of Australian history;' this was published in Sydney in 1889. Returning to England in 1883 as commissioner for New South Wales to the Amsterdam exhibition of 1884, he took up the advocacy of cheap postal and telegraphic rates between the mother-country and her colonies with which his name is indissolubly connected. In 1885, as representative of Tasmania at an international telegraphic conference in Berlin, he obtained a reduction in the cable charges between England and Australia; being in November of that year elected to the house of commons from Canterbury (which he represented uninterruptedly till 1910), he pursued his campaign there with vigour, and in 1891 procured the reduction of Anglo-colonial postage rates from 6d. to 2½d. the half-ounce; almost immediately he began a campaign for a further reduction to 1d. per half-ounce, and this was secured in 1898; and by 1908 he had persuaded the government to make the same concession with regard to postage between Britain and the United States. He also procured other postal reforms (such as the introduction of telegraphed money orders), and till his death fought hard to lower still further the cable rates between England and Australia. He died at Geneva on 8 September 1914. (Baronet, 1912.)

Helichrysum, a large genus of the family Compositae, popularly known as everlastings, and consisting of herbs, undershrubs, or shrubs with leafy stems, often clothed with cottony wool. Represented in most warm and temperate regions, it is especially varied and widely distributed in Western Australia, in which about 70 species are endemic. The involucral bracts are usually rigid and scarious, simulating petals; pappus bristles simple, barbellate, or plumose at the tips only. *H. lucidum,* with numerous horticultural varieties, is largely cultivated as a garden plant; the white-flowered varieties, under the name of immortelles, are used in making funeral wreaths. *H. ferrugineum* (Native Lavender), a strongly scented shrub, has small flowers with shining bracts collected in groups (corymbs); *H. rosmarinifolium* is a handsome, very floriferous shrub; and two Tasmanian species, *H. lycopodioides* and *H. selaginoides,* have moss-like leaves.

Helipterum, a genus of the family Compositae, consisting of annual and perennial herbs, rarely shrubs. It is confined to South Africa and Australia, the species in each region being endemic. The involucral bracts frequently have petal-like laminae; pappus bristles plumose from the base. The western *H. roseum* and *H. Manglesii* (better known to nurserymen as *Acroclinium* and *Rhodanthe* respectively, and often erroneously called 'everlastings') are largely cultivated and used for decorative purposes. *H. incanum,* of which there are both white and yellow varieties, is very ornamental. In alpine regions it is thickly coated with silky hairs and dwarfed, flowering when only one or two inches high.

Hematite. See IRON.

Hemiptera, a large order of insects, including cicadas, hoppers, plant-lice, scale-insects, and bugs; it is well represented in Australia, where the number of described species is little short of 2000—and this is only a small part of the total hemipterous fauna of the continent. Of these more than 1000 belong to the Homoptera, while the Heteroptera number less than 900.

The order as a whole is difficult to define, but its members may be recognized at once by the possession of a jointed sucking-beak differing in structure from that found in any other group of insects. Fore- and hind-wings differ greatly in size, shape, and venation; in most cases, the fore-wing is much tougher than the hind, being a kind of tegmen. The legs have tarsi with never more than three joints, and there are no cerci. As a general rule, the larval stages differ little from the imago, though in some advanced Homoptera the male may undergo a very striking metamorphosis.

The Hemiptera are naturally divisible into two very distinct sub-orders, considered by some to be two separate orders; but both can be traced back to a common stock in the Permian

era, and they stand so far apart from all other insects that they are best treated as a single order.

The sub-order Homoptera is distinguished by the unspecialized form of the fore-wings, in which there is no division into corium and membrane (see below under Heteroptera), by the fact that the species (with few exceptions) hold their wings roofwise over the body while at rest, and by the head being so bent under the thorax that the beak projects far backwards, extending between the front coxae. Cicadas (q.v.) belong to this sub-order. Their nearest relatives are the Cercopidae (spittle insects), of which only 30 have been up to now described from Australia. The sub-family Cercopinae, containing the true spittle insects, is represented by several genera, of which the most abundant is *Philagra*. In this genus, which occurs on *Casuarina* trees, the head of the imago projects far forward like a snout. In the Machaerotinae (tube-forming cercopids) we have the two interesting genera *Pectinariophyes* and *Polychaetophyes*, which form delicate tubes attached to the stems of eucalyptus saplings; the larvae live inside these tubes in their own froth, and suck the sap of the stem.

Closely related to the Cercopidae, but at once distinguished by their transverse hind-coxae and angulated hind-tibiae, are the Jassidae (plant-hoppers), very abundant in Australia as elsewhere. About 200 Australian species have been described, but very many are still undescribed. Our most striking sub-family is the Bythoscopinae, containing the genus *Eurymela* and its allies—rather large, broad-headed hoppers of dark and striking coloration, which sit about on stems of eucalyptus saplings, and are generally attended by ants. Plate xix fig. 8, shows the handsome but common *Eurymela bicolor*.

The Ledrinae include some large brown jassids with very prominent prothorax, rounded in front. The allied Stenocotinae also contain large brown forms, peculiar to Australia; their larvae are very flattened, and may be found under bark. Amongst the numerous smaller forms (placed in several sub-families) the little hoppers of the genus *Ipo*, with their broad heads and wedge-shaped bodies, are very common; other well-known genera are *Tartessus*, *Idiocerus*, *Xestocephalus* and *Vulturnus*.

The Membracidae (tree-hoppers) are much like Jassidae, but are specialized by the extraordinary development of the pronotum—which in Australian species usually extends forward and upward in the form of two large horns of various shapes. Our best-known genera are *Sextius*, *Eufairmairea*, *Daunus*, and *Centrotypus*. We have about 40 named species.

The super-family Fulgoroidea includes all hoppers originally placed in the old family Fulgoridae, and now split up into a number of distinct families. All are recognizable by the long and well-separated middle coxae, and by the presence of a distinct tegula in the form of a small scale at the base of the tegmen; usually, moreover, the veins of the anal area (clavus) of the tegmen form a distinct Y. About 250 Australian species are known, and many more must be awaiting description. Plate xix, fig. 9, shows the beautiful *Desudaba danaë* from Queensland and fig. 10, the pretty, green, moth-like *Siphanta acuta*, a very common species. *Achilus flammeus* is a handsome rose-red insect, not uncommon. We have a number of peculiar long-winged Derbidae, of which some fine species of *Zoraida* are still undescribed.

Passion-vines, especially in Queensland, are injured by a frog-hopper (*Scolypopa australis*), which in some seasons appears in great numbers. These insects also infest species of *Solanum*; and, when they are disturbed by the passage of a horseman through a batch of plants, their hopping makes a noise resembling a hailstorm.

Psyllidae (lerp-insects) are numerous in Australia, and almost entirely replace the more advanced family Aphidae. About 80 species of psyllids have been described; perhaps the best-known is the Sugarlerp-insect (*Spondyliaspis eucalypti*). Species of *Psylla* are very abundant on wattles, and sometimes quite destroy the flower-buds of these trees. 'Lerp' is the glutinous matter secreted by psyllids in their larval stage and exuded by them.

The minute Aleurodidae (snow-flies) are represented by a few species; it is easy to confuse them with the tiny white Coniopterygidae of the order Planipennia (q.v.), which they much resemble superficially. Like the Coccidae, with which they are also confused, they live on the juices of plants, being furnished with a sucking-tube. Both sexes have two pairs of wings. Their name is derived from the white dust with which they are clothed. The larva, as it emerges from the egg, constructs a scale-like covering, beneath which it develops. About eight Australian species have been described. One cosmopolitan aleurodid is common in plant-houses and gardens, and another is a pest on orange-trees in America. The Coccidae (q.v.) also belong to this sub-order.

The sub-order Heteroptera includes the true bugs and water-bugs, which are probably almost as numerous in Australia as the Homoptera, but have not received such careful attention. They are at once recognizable by the form of the fore-wing, which is known as a hemiëlytron (half-sheath); the basal half (corium) is hard, the distal half (membrane) more delicate and membranous, with a sharp dividing line between the two portions. The wings are held flat on the back, and the beak is inserted near the anterior end of the head. Of the terrestrial families the most abundant (and one of the most highly specialized) is the Pentatomidae, of which nearly 400 species have been described from Australia, mostly by Distant. Many species are brilliantly coloured; most have a very offensive musk-like odour and, being almost exclusively plant-feeders, are often injurious to both fruit and vegetables. Our most abundant genera are *Tectocoris*, *Chaerocoris*, *Poecilometis*. *Dictyotus*, *Cuspicona*, and *Rhoecocoris*. Plate xix, fig. 12, shows the large and handsome *Oncomeris flavicornis*, from northern Queensland. Much less numerous in species are the Coreidae, a group in which the scutellum is much shorter than in the previous family. A well-known example of this family is the Crusader-bug (*Mictis profana*), a dull-brown species, carrying a conspicuous cross on the hemiëlytra; it is common in the bush, and sometimes damages citrus orchards.

The Pyrrhocoridae only differ from the last-named family in having no ocelli. There are few Australian species; *Dindymus versicolor* (Harlequin Bug), is a handsome red-and-black insect, which does much damage in gardens.

The Lygaeidae (chinch-bugs) are represented in Australia by more than 100 species, mostly of small or moderate size, and often marked with

red. Our most notorious species is the Rutherglen Bug (*Nysius vinitor*), one of the very worst pests on grape-vines and crops of all kinds, including wheat and potatoes.

The Berytidae (stilt-bugs), the Tingidae (lace-bugs), the Aradidae (fungus-bugs), the Miridae (leaf-bugs), and the peculiar, truncated Gelastocoridae, are represented in Australia by a total of barely 100 species altogether, of which the Miridae claim about 50. Little is known about them, and many more species are sure to be found. The Reduviidae (assassin bugs) are a carnivorous group, and therefore potentially of economic value. They can be at once distinguished by the stout, curved beak, the elbowed antennae, and the large basal cells on the membrane of the hemiëlytron. About 120 species have been described from Australia, many of them very handsome insects. Plate xix, fig. 13, shows the Western Australian *Havinthus rufovarius*, a beautiful red-and-black species.

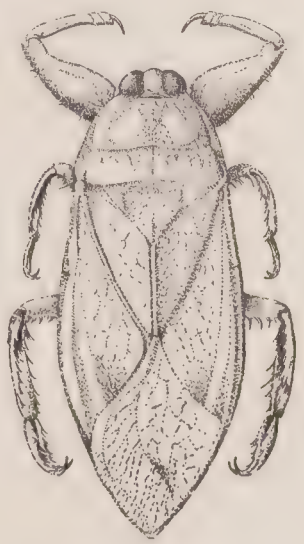
Comparatively few bugs are serious pests, and but few have been introduced; but that universal denizen of unclean dwellings, the Bed-bug (*Cimex lectularius*), is too often in evidence. Though not definitely proved to carry disease, this pest has been suggested as a transmitter of kala-azar (Leishmaniasis) as well as of leprosy. Cotton-plants in the Cairns district are attacked by a large bug (*Tectocoris diophthalmus*), which varies in colour from purple to red. This is one of the few insects—outside the 'social Hymenoptera'—that shows maternal care of its offspring, since the female watches over the eggs and newly hatched young for some time. This and the graceful *Dysdercus sidae* (which attacks maize as well as cotton) range to Papua and the Malay region, and *Dysdercus* is found in New South Wales. The twigs and fruit of oranges in New South Wales and Queensland are punctured by a large bronze bug, *Rhoecocoris sulciventris*. This insect, when disturbed, ejects an acid and evil-smelling fluid that often painfully affects the eyes of pickers. *Biprorulus bibax* is a large green species, with two conspicuous spines, and injures twigs and fruit in a similar way.

The harlequin or soldier bug (already mentioned), besides swarming through apple orchards, attacks other insects and sometimes even its own kind, and may be seen walking off with a much larger insect, after the manner of the assassin bugs.

The Cherry-bug (*Peltophora picta*), the Coon-bug (*Oxycarenus luctuosus*) that swarms on cucumbers, potatoes, and similar plants, the Rice-bug (*Plautia affinis*), that attacks cereals, and the Olive-bug (*Froggattia olivina*), have also been recorded as pests.

Oechalia consocialis is one of the few useful Australian bugs. It destroys cutworms and other destructive insects, and one may often be seen on a grape-vine, bearing off a caterpillar many times its own weight. A species of *Gminatus* similarly destroys the pear- and cherry-slug in Tasmania. *Cermatulus nasalis* and *Glaucias amyoti* are also useful species.

Little attention has been paid to Australian water-bugs, and the number of described species is small. The Gerridae (water-striders) are represented by about a dozen species of *Gerris* and *Hydrometra*, as well as by a few species of the marine genera *Halobates* and *Hermatobates*. *Halobates whiteleggi* is found in Port Jackson. The Belostomidae are represented by the Giant Fish-killer (*Lethocerus indicus*), a huge insect reaching nearly three inches in length, and frequently taken at night, and by the curious genus *Sphaeroderma*, consisting of



Giant Fish-killer.

medium-sized oval bugs which inhabit water-weeds and carry their eggs about on their backs. The Nepidae (water-scorpions) are represented by a few species of *Nepa* and *Ranatra*; the huge *R. filiformis* is popularly known as toe-biter, from its vicious habit of wounding the feet of bathers. The Corixidae (water-boatmen) and the Notonectidae (back-swimmers) are abundant in ponds and rivers; but few species have been named.

See Tillyard's *Insects of Australia and New Zealand*.

Henderson, SIR EDMUND YEAMANS WALCOTT (1821-1896), son of Vice-admiral George Henderson, was born on 19 April 1821 at Middiford in Hampshire, educated at Woolwich, and entered the royal engineers (lieutenant, 1838; captain, 1847; major, 1858; lieutenant-colonel, 1862). From 1839 to 1845 he was stationed in Canada, and in June 1846 was again sent to that colony to survey a boundary between Canada and New Brunswick in the area ceded by the United States under the Ashburton treaty. He returned to England in November 1848, and in 1850 was appointed comptroller-general of convicts in Western Australia, a position which he held until 1863. To his wise administration is mainly due the fact that the convict system left so little stain on the colony. In 1852 he became an official member of the legislative council. Resigning in 1863, he returned to England and was appointed chairman of directors of prisons and surveyor-general. He retired from the army in 1864. In 1869 he was appointed chief commissioner of the metropolitan police, but resigned in 1886 in consequence of the Trafalgar Square riots. During his occupancy of the position he instituted the criminal investigation department. He died on 8 December 1896. (C.B., 1868; K.C.B., 1878.)

J.S.B.

Henry, LUCIEN. See ART.

Henty, EDWARD (1809-1878), the best-known member of a Sussex family that did pioneering work in three Australian colonies, was born at West Tarring in Sussex on 10 March 1809. In May 1829 his father, Thomas Henty, who was a breeder of merino sheep and eager to establish himself in the Australian region which he had heard was so suitable for them, sent out three of his sons (James, John, and Stephen) to the Swan River settlement, with 33 labourers and servants from the village of West Tarring, and 147 sheep. They reached Perth on 12 October, and James Henty promptly claimed land to the value of over £6000 (over 84,000 acres). The best and most accessible land, however, had already been allotted, and after two years of heart-breaking work they found their stock depleted by starvation and poisonous feed, and determined to shift to Tasmania. Here they settled at Launceston, and in 1832 were joined by their father and the rest of the family, Edward among them. Finding Tasmania also unsuitable—the price of land being too high and the area available too small—Thomas at the beginning of 1833 sent Edward off in a whaler to explore the southern coasts of the mainland; he investigated the shores of Spencer Gulf without success, was picked up at Port Lincoln by a schooner belonging to his father, and on the way back to Launceston anchored in June off the whaling station in Portland Bay. He explored the country for about 25 miles inland, and decided that it was exactly what he was looking for; in December he took his father there and secured his approval, and on 17 February 1834 Thomas Henty applied for a grant of 20,000 acres at 5s. an acre for himself and his seven sons. This being refused, Edward on 14 November left Launceston in the *Thistle* with 17 head of cattle and a miscellaneous collection of seeds and fruit-trees. He reached the Bay on the 19th, found it deserted, and proceeded to establish himself ashore; in December his brother Frank joined him, bringing the first merino sheep landed in Victoria, and when the whalers returned early in 1835 they found the new arrivals settled and comfortable. In after years William Dutton (q.v.) claimed that he had built a house at the Bay in 1829, and lived in it year by year, and was therefore the first colonist in Victoria; but Henty's was undoubtedly the first permanent settlement for cultivation of the land. In 1836 Stephen Henty, who had been left in Western Australia to wind up the family affairs there, joined his brothers and embarked on a whaling enterprise, and during the next few years Edward and Stephen explored the country north to the Wannon and west to the Coorong.

Although everyone in Launceston must have heard of the Hentys' settlement, it was otherwise unknown; and Mitchell, coming down on it on 29 August 1836 from his journey across the mallee country, was astonished to find tracks of cattle and the shoe-marks of a white man. It was his account of the land along the Wannon that sent Stephen and Edward in that direction, and just a year after his visit they placed their sheep on Merino Downs. Meanwhile Thomas Henty had been, through his son James, negotiating with the colonial office in London for the right to retain the Bay property in the family if settlement should at any time spread so far; this was necessary because in law the Hentys were merely trespassers on crown lands beyond the authorized bounds of settlement (which was then confined to the 'twenty counties' in New South Wales). Lord Aberdeen, the then colonial secretary, solemnly expressed his surprise that anyone should have dared to occupy land before the authorities in London had decided that it was ripe for occupation, but hinted that the Hentys might be given a title to any land actually fenced and cultivated. In 1840, however, the authorities in Sydney decided to lay out a township at Portland and sell allotments by auction, and refused to give the actual occupiers any advantage; Gipps, indeed (backed by Lord John Russell), denounced them as troublesome and objectionable, sold the land over their heads for £551 per acre in the township and £11 within two miles of the town, and early in 1842 took steps to eject them; but Russell's successor, Lord Stanley, held that Lord Aberdeen's hint was binding on him, and offered the Hentys all their fenced and cultivated area at the price of 'unimproved' land. In 1846, however, they obtained a free grant of land valued at £1290 and were compensated for the improvements they had made to the port.

Thomas Henty died in 1839, and in 1842 the brothers dissolved partnership. Edward, John, and Francis squatted along the Wannon, Stephen stayed at Portland; James had already a shipping and mercantile business in Launceston, Charles became manager of a bank, and William, who was trained for the law and in 1837 was admitted to the Tasmanian bar, entered the Tasmanian legislature and from April 1857 to November 1863 was colonial secretary in four successive ministries. Edward represented Normanby in the Victorian legislature from 1857 to 1861, then went back to his station, and died in Melbourne on 14 August 1878. Frank died there on 15 January 1889; James went to Victoria in 1851, was for a time a member of the legislative council, and died in 1882; and William, who returned to England at the end of 1862, died at Brighton on 11 July 1881.

Hepaticae. See LIVERWORTS.

Herbert, SIR ROBERT GEORGE WYNDHAM (1831-1905), a grandson of the first earl of Carnarvon, was born at Brighton in England on 12 June 1831, educated at Eton and Balliol College, Oxford (Hertford, Ireland and Eldon scholar; B.A., 1854; fellow of All Souls'; D.C.L., 1862), called to the bar in 1858, and brought out to Queensland by the first governor, Sir George Bowen, at the end of 1859. Bowen made him at first colonial secretary, then premier, and the constituency of Leichhardt returned him unopposed to the first parliament. For six years he ruled the new colony, partly by merit—for his ability was unquestioned—partly by virtue of the governor's unswerving support, and was responsible for the important measures on which Queensland's subsequent land and education policy have been based; these were the crown lands alienation act of 1860, with which R. R. Mackenzie (q.v.) aided him, and the education act and grammar schools act of 1860. Young, ardent and opinionated, he offended many good Queenslanders by his assumption of superiority and his early endeavours to model the colony's institutions on English patterns; but he was a quick learner, and during his long term of office repaired most of his own faults. In 1866 private business made necessary his return to England; he resigned the premiership on 1 February, took it back again (without portfolio) for about three weeks in July-August

to get the governor out of a difficulty, and sailed for England on 20 August. His colonial experience was soon put to use there. In 1868 he was made assistant-secretary to the board of trade, and in 1870 assistant under-secretary to the colonial office; the next year he became permanent under-secretary of state for the colonies, and held the position until 1892, and in 1899-1900. From 1893 to 1896 he was agent-general for Tasmania, and in 1904 chairman of a commission—privately appointed, but of some importance because it was connected with Joseph Chamberlain's tariff reform movement—which investigated the tendency of British trade-relations with the rest of the Empire. He died on 8 May 1905.

Herbert's career is full of minor incidents to which justice cannot be done in a summary. For a short time in the fifties he was private secretary to W. E. Gladstone, and the friendship was never broken; it is possible that several of the mannerisms which diminished Herbert's popularity in Queensland were acquired at that period. His father was a keen botanist, and the son developed a like taste for bird-lore, and took many Australian birds with him when he returned to England, for acclimatization on his estate in Cambridgeshire. At one time—towards the end of the century—he was adviser to the Sultan of Johore; and from 1892 until his death he was chancellor of the order of St. Michael and St. George. (C.B. and K.C.B., 1882; G.C.B., 1902.)

Hermit Crabs, marine crustaceans of the tribe Paguridea, one of the three tribes of the sub-order Anomura, order Decapoda. For convenience' sake the other two tribes, Galatheidea (porcelain crabs, etc.) and Hippidea (turtle and mole crabs), are dealt with under this heading below. The Anomura as a whole have been called 'irregular-tailed' crabs because in them the abdomen may be straight, more or less curled up under the body, or spirally coiled and asymmetrical; the last pair of legs is always reduced in size. The typical hermit crabs are well differentiated, but other Anomura may resemble both higher and lower forms. The Paguridea include four families, of which only one, the Paguridae, is importantly represented in Australia. Species of this family are plentiful on every section of our coasts; they may be found along the shore-line in harbours and estuaries, but more frequently inhabit deeper waters. The name 'hermit crab' is popularly applied to species that utilize the empty spiral shells of molluscs to protect their soft abdomens, because they have no hard outer covering (as have most crabs), but are wholly fleshy, and would offer, if unprotected, tempting morsels to hungry sea animals. The half-naked crabs are modified to suit the conditions of their life. The abdomen is spirally twisted; one of the claws is much bigger than the other, and closes the opening of a shell after the rest of the body is drawn in, thus barring the door against intruders. The creature is therefore rarely in danger, except when it is changing to a new shell from an old one that has become too small for it (this move is performed wonderfully quickly, the crab never leaving its old home till it has found a new one). Behind the claws occur two pairs of legs, which are strong and pointed. As the crab walks, these secure a firm hold of the ground, and enable him to draw a heavy shell after him. The two delicate pairs that follow are provided with roughened surfaces, which grip the smooth inner surface of the shell and enable the crab to shift its body within its house. Swimmerets, which are well developed in a few ancestral types, are reduced to small and stunted appendages in most hermit crabs. The 'tail-fan,' no longer broad and flat, is turned into a kind of grappling hook, which can secure such a firm hold of the smooth inner surface of a shell that the crab is scarcely ever dragged out alive.

Among the larger hermit crabs found along our coasts is the Stridulating Crab (*Clibanarius strigimanus*), characterized by the possession of series of ridges on the inner surfaces of the joints of the pincer-bearing limbs; when these are rubbed together, a peculiar rasping sound is produced. This species, along with the Scaly-legged Hermit Crab (*Dardanus arrosor*), another species of about the same size, occurs commonly in shallow water along most of the eastern and southern coast-lines. Many smaller forms, such as the Hairy-footed Hermit Crab (*Paguristes squamosus*), are found in rock-pools along the coast, more particularly in the tropics.

Certain members of the Paguridae have discarded shells as habitations, preferring other homes. Some live in corals, others in cavities in sponges; one is known to protect its abdomen by a cloak of living sea-anemones, held in position by its hinder legs, while another lodges itself in the mass of a soft marine animal colony called a zoantharian. A unique and remarkable

Miner Crab (full length).

form is the Miner Crab (*Cancellus typus*) of Port Jackson. This crab has an extended and bilaterally symmetrical abdomen; it lives in burrows, which it excavates in soft stones and cinders by the use of horny plates on its tail and posterior legs. When undisturbed, it roams about in search of food, dragging its often bulky abode after it; if alarmed, it withdraws into the burrow, and closes the aperture in the same way as

do other hermit crabs, its claws forming a close-fitting operculum.

The next tribe (Galatheidea) includes in its four families the Porcellanidae (porcelain crabs), and the small lobster-like crustaceans of the typical family Galatheidae. These latter have the body symmetrical, and the abdomen bent upon itself. The last pair of legs is slender, and is carried folded up close to the sides of the carapace. The last pair of abdominal appendages (uropods) is large, and, with the telson, forms a well-developed 'tail-fan.' The species of this family are distributed throughout the seas of the world; many live in deep water, and have extremely wide ranges. Perhaps the species commonest in Australian waters is *Munida subrugosa*, remarkable for its gregarious habits. As this species affords abundant food for the larger aquatic mammals, it has become known as

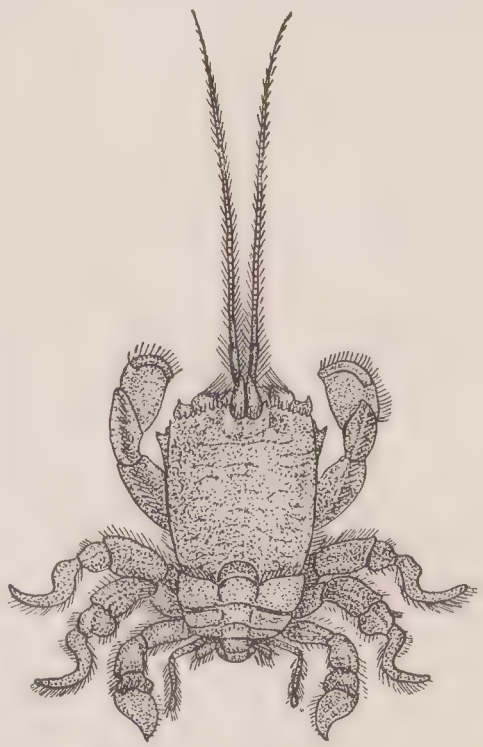
Miner Crab (from above, in burrow).

Munida subrugosa (slightly magnified).

'whales' food' in New Zealand, where it is particularly abundant. At times it has been observed congregating in millions on the surface of the sea, so that the water appears tinted with the red colour of the crustacean.

Porcelain crabs have a short and broad carapace without a prominent rostrum; although they are closely allied to the lobster-like Galatheidae, their habit of carrying the abdomen folded under the body gives them quite a 'true crab' appearance. Some species have all four pairs of legs visible, though the last pair is folded up close to the sides of the carapace, as in the Galatheidae; others have only three pairs of legs visible, the last pair being hidden within the branchial chambers beneath the carapace. The family is abundantly represented along the whole length of our coast-line, particularly in the tropics. Some species are of comparatively large size, and are ornamented with striking colours. *Porcellana dispar*, a tiny reddish-coloured species with a wide distribution on the eastern, southern and western coasts, is commonly found beneath stones at low-tide mark in harbours and river estuaries.

In the small tribe Hippidea are included some small burrowing forms, found only in tropical and subtropical seas, which live in sand and have the feet flattened for digging. The carapace is generally smooth and more or less oval; as in the Porcellanidae, the abdomen is folded under the body, but not so completely as in the true crabs. The tribe includes two families, the Albuneidae and the Hippidae, both represented in our fauna. A typical member of the Hippidae is the Turtle Crab (*Hippa adactyla*), a frequenter of coral lagoons, where it burrows in the sand at the water-level. It is amazingly active, and can be procured only by suddenly dislodging the sand from the spot where one has been observed burrowing. When uncovered in this way, it must be immediately secured, or it will disappear like a flash beneath the surface again. The family Albuneidae also graces our shores with a typical member, the



Mole Crab (natural size).

Mole Crab (*Albunea symnista*) which burrows like the turtle crab, and is fairly common on estuarine beaches in the subtropical zones. While buried, it carries on respiration through a tube formed of two rows of stiff hairs along the edges of the long antennules or inner feelers. The carapace of the mole crab is squarer in front than that of the turtle crab. F.A.McN.

Heron, Emily Matilda (1845-1890), second daughter of Sir W. M. Manning (q.v.), was born in New South Wales in 1845, and at an early age began to write pleasant but not particularly distinctive verse, also contributing miscellaneous articles to the local newspapers over the pen-name 'Australie.' In 1873 she married Henry Heron, a local solicitor, and in 1877 published in London her one volume of verse—*The Balance of Pain*. She died at Sydney on 25 August 1890.

Herons, Egrets, and Bitterns, large, long-legged birds with long necks and bills,

belonging to the family Ardeidae and order Ardeiformes. The family is largely represented in Australia, where its members are usually called cranes; but the only true Australian crane is the native companion (q.v.).

By far the commonest member of the family throughout the continent and Tasmania is the White-fronted Heron (*Notophoyx novae-hollandiae*), generally known as 'blue crane.' The

White-necked Heron.

larger and handsomer White-necked Heron (*N. pacifica*) is also familiar in districts suited to its habits. Herons that are adorned with ornamental plumes during the breeding season (mostly white herons) are known as egrets. The plumes are largely used to adorn ladies' hats, and are known by milliners as 'ospreys' or 'aigrettes.' As the plumes only appear during the breeding season, the collection of them necessarily involves the starvation of the young birds, whose parents are slaughtered for the decoration of thoughtless or heartless women. In Australia and its dependencies the possession of egret feathers is now a misdemeanour, and their export or import is forbidden. There are signs that the protection thus afforded the birds is already leading to an increase in their numbers. The large White Egret (*Egretta alba*) is the commonest and most widespread species; the Lesser Egret (*E. garzetta*) is not uncommon in northern and eastern Australia. Egrets breed in 'heronries,' building their nests close together in trees growing in a swamp.

The Reef Heron (*Demigretta sacra*), a small species found all round the Australian coastline, is interesting for its dimorphic coloration. The common colour is very dark blackish-slate, the rarer variety being pure white, though not an albino; the latter is only found on our northern coasts, and does not extend far south of the Tropic of Capricorn.

The attractive Nankeen Night-heron (*Nycticorax caledonicus*) is fairly plentiful throughout Australia and Tasmania, and occurs also in the Malay Archipelago and New Caledonia. The adults are of a beautiful cinnamon colour, with a black patch on the head and two long, narrow, pure white plumes on the back of the neck;

Nankeen Night-heron.

the young birds retain their immature plumage (mottled brown and dirty white) for two years. These birds are mainly nocturnal in their habits, and spend the day roosting in trees, so that they often escape observation.

Bitterns are also largely nocturnal and hard to see; though their necks are long, they usually carry them retracted, so that the general appearance is much more compact than that of herons and egrets. When alarmed, however, they draw themselves out to their full length, with the bill pointing straight upwards, and remain rigid and motionless; in this attitude they are more inconspicuous than ever amongst the reeds which most of the species frequent. The largest of the bitterns is the Australian Bittern (*Botaurus poiciloptilus*), which makes a loud booming noise during the evening and night. Two other common swamp inhabitants are the Black Bittern (*Dupetor flavicollis*) and the Little Bittern (*Ixobrychus minutus*); the Mangrove Bittern (*Butorides stagnatilis*)—as its name implies—inhabits mangrove thickets wherever these trees occur on our coasts. W.B.A.

Herring Cale. See PARROT-FISH.

Herrings (Clupeiformes). A large number of herrings are known from Australian waters, but although some of them occur in vast shoals, very few are utilized as food. Pilchards (*Sardinia*), sprats (*Clupea*), and anchovies (*Engraulis*) occur on the south-eastern coasts of Australia and Tasmania in enormous numbers, but no systematic effort is made to utilize them commercially. In the tropics a number of herrings of the genus *Harengula* move in shoals throughout the year, and are so closely packed that a spear thrown into their midst will often impale several specimens together. In Torres Straits these fishes form a large portion of the natives' food-supply.

The coastal rivers of New South Wales are inhabited by a freshwater herring (*Potamalosa richmondia*) which reaches a length of 12 inches. It readily rises to a fly, and small specimens are excellent eating, though larger ones are very bony. The so-called bony bream (*Nematalosa*)

is another freshwater herring. The 'Yarra herring' of southern Victoria and northern Tasmania (*Prototroctes maraena*) is not a herring at all, but a grayling. See ANCHOVY, BONY BREAM, PILCHARD and SPRAT. A.R.McC.

Heterodendron, a genus of the family Sapindaceae, with 2 species, both endemic in Australia. *H. oleaefolium* (Western Rosewood) is a tall shrub (20-25 feet) with narrow, usually rigid leaves, and small flowers without petals. It is found chiefly inland, ranging across the continent, and is highly prized as a fodder-tree. Recent investigations have shown that large quantities of prussic acid may be obtained from the leaves; but systematic feeding experiments will be necessary before it can be definitely decided that the plant is fatal to stock. The seeds are eaten by emus and by the aborigines. The timber is of a yellowish colour, hard and heavy. *H. diversifolium*, a shrub with very variable foliage, extends from New South Wales to Queensland.

Hibbertia. See DILLENIACEAE.

Hibiscus, a large genus of the family Malvaceae, consisting of herbs, shrubs or trees whose leaves are frequently coated with star-like hairs. Its habitat is chiefly tropical, and of the 40 species indigenous to Australia, which range right across the continent, only one (*H. Kriechauffii*) is found in Victoria. The flowers are usually large and showy, with petals deepening in colour towards the base. *H. heterophyllus*, which ranges from New South Wales to Queensland, is known as the 'green kurrajong.' Its mucilaginous leaves are greedily eaten by stock; the aborigines also eat leaves and roots without any preparation. It has a pale-coloured, smooth, tough wood, suitable for musical instruments, as it is a good conductor of sound. The fibre, which is white, strong and of fine texture, the aborigines use after maceration for making dilly-bags. *H. Trionum* (Bladder Hibiscus) is so called from the inflation of the membranous calyx, which enlarges as the fruit matures. It is a common weed in most tropical countries, though also grown as an ornamental garden plant. *H. tiliaceus* (Cotton-tree) is found from New South Wales to northern Australia, as well as in the Pacific islands. It has a beautifully marked, easily worked wood, resembling that of pollard oak. Its bark, which abounds in mucilage, provides sustenance for South Sea islanders when the bread-fruit crop fails. The aborigines of central Queensland prize the roots as a food, and in times of scarcity eat the tops, which taste like sorrel. The bark fibre they use for nets and fishing lines. In Fiji the bark is used to make the waist-band (liku) of the women. *H. splendens* is a highly ornamental shrub, with flesh-pink flowers, frequently cultivated.

Hickory. See ACACIA.

Hicksbeachia, a genus of the family Proteaceae; the single species is endemic in eastern Australia. The corolla is regular, tube straight, the segments soon parting; stamens inserted on the corolla lobes; fruit a nut. *H. pinnatifolia* (Monkey Nut) is a tall shrub or slender tree, with an edible fruit, the favourite food of the ring-tailed opossum. Pinky-red when ripe, it has an acorn-like flavour resembling that of the Queensland Nut (*Macadamia ternifolia*); but the shell is much softer.

Higgins, HENRY BOURNES, born at Newton Ards in Ireland in 1851, and educated at Newry and the university of Melbourne (B.A., 1874; M.A., 1875; LL.B., 1875), migrated to Australia in 1870, was called to the Victorian bar in 1876, and admitted to the English bar from the Inner Temple in 1886. In 1887 he was leader of the equity bar in Victoria. Entering politics in 1894 as member for Geelong, he made his mark during the next few years as chairman of a royal commission on legal procedure (1897-9) and as a member of the judiciary committee of the federal convention of 1897-8. He was not, however, a supporter of the convention's proposed constitution, considering it over-rigid; the senate, he thought, was constituted on a wrong basis, the machinery for overcoming deadlocks was inadequate, and the determination to leave Australia's railways in the hands of the several States was erroneous and might be disastrous. He consequently acted with the Victorian Labour party in its attempts to throw out the federation bill. In 1901, however, as soon as federation was an accomplished fact, he entered the federal parliament as member for Northern Melbourne, and in the second parliament became attorney-general in J. C. Watson's Labour ministry of 1904, although refusing to join the party. On 18 October 1906 Higgins was made a justice of the high court with the special duty (in which he succeeded Judge O'Connor) of presiding over the federal court of conciliation and arbitration. His work in this position—which he afterwards described in three articles in the *Harvard Law Review* (Nov. 1915, Jan. 1919, and Dec. 1920)—was of great importance, as it fell to him to lay down the principles on which federal arbitration awards must be based (for these see INDUSTRIAL LAW). His first decision—in what is known as the 'Harvester' case—gave a key to his interpretation of the law. A good deal hung on it. If he decided that the remuneration of employees of firms manufacturing harvesters was 'fair and reasonable,' the excise duty on harvesters would be considerably diminished. He at once laid down the doctrine of the 'basic wage,' fixing 42s. per week as the lowest pay that would in Melbourne support an unskilled labourer in frugal comfort, and declined to certify that any lower wages were 'fair and reasonable.' The amount of the basic wage has been frequently altered to meet the altered purchasing power of money; but the principle is now generally accepted. In 1922, considering that the powers of the arbitration court were unduly diminished by certain legislation, he resigned the presidency of the court, retaining, however, his seat on the high court bench. Apart from politics and judicial work his chief hobbies have been literature and physical culture. He has been a member of the council of the university of Melbourne since 1887, and in 1904 founded a scholarship at the university for the study of poetry.

High Court, The. See JUDICIARY.

Higinbotham, GEORGE (1826-1892), born in Dublin on 19 April 1826 and educated at Trinity College, Dublin (B.A., 1848; M.A., 1853) in 1847 went to London to study law, earned his living as a reporter for the *Morning Chronicle*, and was called to the bar on 6 June 1853. Early in 1854 he migrated to Melbourne and on 27 March was admitted to the Victorian bar. He continued to combine journalism with law, writing occasionally for the *Herald* and at the same time practising his profession. In 1856 he dropped his practice to become editor

of the *Argus* (in succession to Edward Wilson), but in 1859 he resigned the editorship and resumed his profession. In May 1861 he entered political life as member for Brighton in the assembly, voting as an independent Liberal; defeated at that year's general election, he regained the seat in April 1862 and held it for nine years. He opposed the land act of 1862, and the electoral bill. On 27 June 1863 he became attorney-general in the McCulloch ministry, and during the fierce struggle (1865-8) between the two houses over finance bills and the Darling grant was the most popular man in Victoria. On 4 September 1866 he was appointed chairman of the education commission. On 6 May 1868 the ministry resigned; the Sladen ministry held office for two months, and when in July the McCulloch ministry was reconstructed Higinbotham declined the post of attorney-general on the ground that the colony was being governed by instructions from Downing Street. He took, however, the unsalaried position of vice-president of the board of lands and works, but resigned that on 1 February 1869, and never again held office. In 1871 he lost his seat for Brighton to Thomas Bent (q.v.), a local market-gardener who was really more representative of the constituency as a whole. For the next two years he confined himself to practice at the bar, but in May 1873, returned to the assembly as member for the East Bourke boroughs; parliament was, however, in perpetual turmoil, which in 1875-6 culminated in a gigantic 'stonewall,' and Higinbotham in January 1876 left politics for ever, declaring in his last speech 'We are all like common scolds in this House.' On 19 July 1880, he was, to the satisfaction of the community, appointed a puisne judge of the supreme court of Victoria, and in September 1886 succeeded Sir William Stawell as chief justice. During his tenure of this office an important constitutional question arose. Sir W. Stawell had been appointed lieutenant-governor, a position usually held by the chief justice for the time being. When he found it necessary for reasons of health to resign this post also, Higinbotham was his natural successor. But for many years he had been fighting the colonial office, which in his opinion exercised far too much control over Australian affairs, and interfered with the working of responsible government by its advice and instructions to the governor of the day. Before, therefore, he could himself be made acting-governor it was necessary to clear up the points in dispute; and, though the colonial office made many concessions, it remained too stiff-necked for him. When Sir H. Loch during his term as governor wished to leave the colony for a time, the ex-governor of South Australia was put in as his locum tenens: when the situation recurred at the end of 1892, it was decided to install the senior puisne judge, Hartley Williams, over Higinbotham's head. But on 31 December of that year Higinbotham died, and his successor John Madden was made acting-governor without any trouble.

Higinbotham was undoubtedly a great man, one of the very few great men Australia has cherished. But the vehemence with which he urged his opinions alienated many of his more notable contemporaries, and his entire lack of the power to compromise made him comparatively ineffective as a politician. In a crisis he was abnormally powerful: H. Gyles Turner, no great admirer of his opinions, describes him as 'a man who by his intensity of character, the transparent conscientiousness of his convictions, and his burning oratory, exercised a sway over the House which in Victoria has never been equalled.' In less exciting times, although his devotion to work and his absolute unselfishness were recognized and admired, his influence suffered a gradual decay. No greater contrast could be conceived than that between the sarcastic bitterness of his public invective and the urbane courtesy of his private life: if he could have brought himself to treat the colonial office as he in private treated his strongest political opponents, he might have in the sixties brought about those constitutional reforms within the Empire that even in 1911 were scarcely effected. But his references to 'ignorant and transient' ministers and to colonial self-government as being really 'government by a person named Rogers' (the then chief clerk at the colonial office), though scarcely overstatements, were injudicious, and rankled for many years. On the bench his defects hardly showed at all. He has been denied the name of great lawyer because 'he could not lose sight of the object in the instrument'—an objection which at any rate cannot deny him the name of great judge. But twice in his life he effected a consolidation of Victorian statute law—as attorney-general in 1864-5, and as chief justice in 1888-90; and for the second task he received on 16 December 1890 addresses of thanks from both houses of the legislature. He received no decorations or titles, because he would accept none from any authority except those of his own colony—rewards for local services, he said, should emanate from a local source.

Hilder, Jesse Jewhurst (1881-1916), born at Toowoomba in Queensland on 23 July 1881 and educated at the Brisbane boys' grammar school, in 1898 entered the service of the Bank of New South Wales, working in its branches at Brisbane, Goulburn, Bega, and Waverley. While employed at Bega he developed a taste for painting, and when removed to Waverley (a suburb of Sydney) met Fred Leist and was taken in 1906 to Julian Ashton (q.v.), at whose art classes he learnt the technique which his earlier self-taught work had lacked. In the same year it was discovered that he was phthisical, and in 1907 he was again removed to Wyalong on the western plain, from which place he sent 21 water-colour sketches to the exhibition of the Society of Artists. The work made a sensation, every picture was sold—an achievement repeated with the 14 he sent to the Society's exhibition of 1908—and in 1909 he left the bank's employ and devoted himself to art. The rest of his life was spent mainly at Epping, Ryde and Hornsby on the heights north-west of Sydney, from which excursions to the Hawkesbury and Lake Macquarie were easily made; Dora Creek, which runs into Lake Macquarie, was a favourite sketching-ground. He died at Hornsby on 10 April 1916. During the latter part of his life he was prolific as an artist, and was able to live comfortably on the proceeds of private sales; but after his death the value of his work was far better appreciated, and pictures for which he had been paid five or six guineas were re-sold for a hundred guineas or more. Slight as some of his pictures may appear, they have the breadth and vigour of large paintings: his compositions are never strained, and his handling is never affected.

W.M.

Hill, CLEMENT, born at Adelaide on 18 March 1877 and educated at St. Peter's College in that city, entered first-class cricket when only 16, and two years later made a century playing for his colony against Stoddart's team. In 1896 he went to England with an Australian team, and was a member of every succeeding team that visited England until 1905; he also played in every test match in Australia between 1897 and 1912. In test matches he has made 3401 runs, an average of 39.1. Of his 45 centuries four were made in tests. On Australian wickets he ranks as the greatest left-hand batsman ever seen. The highest score made in Sheffield shield contests stands to his credit—365 for South Australia against New South Wales. See CRICKET.

Hindmarsh, SIR JOHN (1782-1860), entered the navy in 1793, and served in the *Bellerophon* in the action of 1 June 1794 and at the battle of the Nile. In this battle the *Bellerophon,* while anchored, was dismasted by the fire of the French flagship *L'Orient* and entangled in her rigging just as she burst into flames (it will be remembered that the boy Casabianca was aboard her, though, Mrs. Hemans notwithstanding, he did not perish in her). At the moment young Hindmarsh was the only officer on the *Bellerophon's* deck; he ordered the cable to be cut and a spritsail to be set, and thus manoeuvred the ship out of danger—a service for which Nelson thanked him, and the ship's officers gave him a sword. Nelson in 1803 summoned him to join the *Victory,* and just before Trafalgar made him lieutenant of the *Phoebe,* in which he took part in that victory. From 1793 to 1813, when he returned to England invalided, his war service was almost continuous, the Nile (where he lost an eye) and Trafalgar being only the two best-known of the many engagements in which he took part. He was promoted commander in 1815 and captain in 1830, and in 1834 was sent to Alexandria to take high command in the Egyptian navy. This appointment was of very short duration, for in 1835 the colonization commissioners for South Australia, being unable to get Colonel Napier on their own terms as first governor, nominated Hindmarsh; he was accepted by the British government, made a Knight of Hanover by the king, and sailed in H.M.S. *Buffalo,* reaching South Australia on 28 December 1836 and there and then officially proclaiming and establishing the province under the old eucalyptus at Holdfast Bay. Almost immediately sharp differences occurred between him (who, as governor, was of course a king's official) and the commissioner for crown lands, J. H. Fisher (q.v.), who represented the colonization commissioners. Hindmarsh (who would have preferred Port Lincoln as the capital) wanted Adelaide to be sited much nearer the shores of the gulf—a wish not unnatural in a seaman, but unpalatable both to the surveyor-general and to most of the settlers; nor was this the only cause of quarrel. In the end it was decided to recall both Hindmarsh and Fisher, and to invest the next governor with full powers in every branch of jurisdiction. Hindmarsh accordingly left the colony in July 1838, and in 1840 was made lieutenant-governor of Heligoland, and given his step to rear-admiral in 1856. He retired from service in 1857, and died on 31 July 1860. (K.H., 1836.)

Hobart capital of the State of Tasmania, lies in 42° 53′ S. lat., 147° 21′ E. long., on the western shore of the Derwent River about 12 miles from the sea. 'Hobart' was the name given by Lieutenant Bowen to his settlement at Risdon in 1803; but Collins, when in 1804 he removed the settlement to the western shore, gave it the name of Hobart Town, and this remained the official name (though in the forties the colonial office favoured 'Hobarton') until in 1881 an act of the Tasmanian legislature restored the abbreviation 'Hobart.' Colonel Davey in 1813 had attempted to make this change, but was sharply rebuked by Macquarie. The story of the settlement up to the death of Collins in 1810 will be found under TASMANIA. At that date the site of the town had been definitely fixed, but not laid out, and the houses (which in 1812 numbered about 150) were scattered irregularly in all directions. After his visit to the settlement in 1811 Macquarie appointed surveyors to draw up town-plans, and himself named the principal streets. In 1813, under instructions from the colonial office, he rescinded the regulations which prohibited masters of vessels from discharging any cargo at minor Australian settlements without first touching at Port Jackson, and thus made it possible for the town to develop into a commercial port; it remained closed against the liquor traffic, however, until 31 December 1814, when the contract for the building of a hospital at Sydney came to an end—under this contract the builders had been given a monopoly of the liquor traffic in the colony (which then included Tasmania) for four years, and the loss of revenue caused by it prevented Davey from erecting several much-needed public buildings. There was no marked development in the town until Colonel Sorell took over the administration in 1817. Macquarie, who made a second visit to the town in 1821, was much impressed by the improvements effected under Sorell's administration. The population had increased to 2700; the irregularly-placed huts and cottages of 1811 had given way to substantial houses (421 in number) fronting regular streets; a government house, military barracks, and a gaol had been erected, and a signal, post and telegraph station established on Mount Wilson; a hospital, convict barracks, and Anglican church were under construction; four water-mills were in operation on the Hobart rivulet; to accommodate shipping a substantial pier was being constructed in Sullivan's Cove. The whaling industry was already important, and had encouraged shipbuilding enterprise. Indeed, by 1819 business had extended so much that the bench of magistrates and the lieutenant-governor's court could no longer deal with the many disputes, and to obviate the expense of frequent reference to Sydney the supreme court judge of New South Wales undertook to hold an annual circuit court in Hobart. The Van Diemen's Land Bank was established in 1823.

When in 1825 Tasmania was constituted a separate colony, there was considerable opposition to the retention of Hobart as the seat of government. On 22 April 1826 Colonel Arthur informed the colonial office that from an administrative point of view the site had many disadvantages. It could only be reached from the north—where settlement was rapidly extending—by a ferry service across the river which was exposed to strong winds and currents, occasioning much delay and expense and no inconsiderable danger to persons and property. To this remoteness Arthur attributed much of the difficulty experienced in suppressing bushranging. Moreover, he considered it desirable to

remove farther inland the mass of convicts that must necessarily accumulate at the chief settlement, so as to minimize their opportunities of escape. Arthur recommended Brighton in the Jordan valley, a site favoured by Commissioner Bigge during his investigations in 1820; the legislative council, however, preferred New Norfolk as being easy of access from inland and in direct connection by water with Hobart—this was an important consideration, as Hobart would remain the principal port of the colony; the government surveyors were not unanimous, but pointed out disadvantages in the site of New Norfolk. Opinion being so divided, Arthur determined the issue on the basis of cost; he adhered to the opinion that Hobart was totally unsuited to be the capital, but it was clear that certain public buildings which were required without delay could be erected more cheaply there than anywhere else. The question had already been decided when the colonial office forbade any change.

By 1827 the population of Hobart had increased to 5000. At that time, according to Arthur, British manufactured goods and European wines were imported in exchange for wool, whale oil, sealskins, extract of mimosa, hides, etc.; from China and the East Indies, tea, rice, spices, piece-goods, and silks were imported; from the Cape of Good Hope, wines; from the Brazils, tobacco; and from the Isle of France, sugar. There was also a steady local trade with Port Jackson. The total declared values of imports at Hobart in 1826 were £99,747 and of exports £44,498.

From the thirties onwards the growth of the capital was conditioned by the development of the colony. The town was governed by commissioners from 1846 until 1852—when a municipal council was constituted—and was incorporated as a city in 1857. Local government brought in its train civic improvements. In 1857 gas-lighting was installed; in 1860 the works installed in 1831 for the distribution of water from the Hobart rivulet were taken over by the municipality and extended; the installation of a sewerage system was delayed until 1903. Since the completion of the Great Lake hydro-electric scheme as a national undertaking (see HYDRO-ELECTRIC DEVELOPMENTS) electricity for lighting and power purposes has been supplied to the city. The zinc-refining works at Risdon a few miles away are among the largest of their kind in the world.

The private schools of Hobart, which have been from the first an important and notable influence in the life of the city, are discussed under SCHOOLS: public education is dealt with under EDUCATION, PUBLIC. The city's newspaper press dates from 1816, when the *Hobart Town Gazette* was published under official auspices; for two earlier attempts to establish local newspapers—the *Derwent Star* in 1810 and the *Van Diemen's Land Gazette* in 1814—see PRESS. A mechanics' institute was founded in 1827; in 1849 a subscription library was established with government assistance, and in 1850 was converted into a public library. The Royal Society of Tasmania—founded in 1838 by Sir John Franklin as 'The Tasmanian Society'—controlled the museum (established in 1848) and the botanical gardens until 1885, when they were taken over by the government. The art gallery was opened in 1889, and the university of Tasmania founded in 1890. The population of the city on 31 December 1923 was 55,243, just a quarter of the total population of the State.

Hobby, THOMAS (1770?-1833), born in England about 1770, was on 9 November 1797 commissioned lieutenant in the New South Wales Corps, and reached the colony in 1798. After doing duty at Sydney for nearly 12 months he was made commandant of the Hawkesbury district, and in December was granted two 100-acre farms at Mulgrave. He promptly resigned his commission, intending to settle down as a sheep-breeder, but repented this action and was allowed to remain in the corps. In 1801 he had 70 acres under crop and was running 140 sheep and 200 goats. In 1803 he was in trouble with Governor King over the circulation of some lampoons, but the British government for the sake of harmony overlooked the irregularity. Before his trial on this charge he had (in March 1803) gone on half-pay, and thenceforth his name did not appear in corps returns until 1807. His farm holdings varied remarkably; at the beginning of 1804 he held 500 acres, at the end of 1805 only 280, yet his flock of 320 sheep did not alter in size. On 1 January 1808 he with other settlers in the Hawkesbury district signed a eulogistic address to Bligh, but before the end of the month had signed another congratulating Johnston on the success of the mutiny, and in March 1809 Bligh included him in a list of the chief mutineers; in 1810 he signed a loyal address to Macquarie. His name invariably comes second on the list of Hawkesbury signatories, and he probably went on quietly all the time with his farming and signed anything put before him to avoid quarrels with his neighbours. Little more is known of him. In 1812 he owed the government nearly £200; in 1811-27 he was assistant coroner at Castlereagh; and he died at Penrith on 8 January 1833. The existence of Hobby's Yards near Bathurst may indicate that he had property in that district also.

Hobson, WILLIAM (1793-1842), born in England in 1793, entered the navy in 1811 (lieutenant, 1813; commander, 1824; captain, 1828) and saw active service in the West Indies in 1822-3 against the piratical bands that infested those regions. By one of these he was captured, but his reputation for courage and generosity induced them to set him free. In 1835 he was appointed to H.M.S. *Rattlesnake*, and in 1836 sent to the Australian station, where Bourke found him very useful. In September he sailed from Port Jackson for Port Phillip with Captain Lonsdale (whom Bourke had appointed police magistrate of the new settlement), and while in Port Phillip surveyed and buoyed Hobson's Bay—which was named after him—and surveyed a good deal of the more open waters towards Sorrento. Returning to Sydney, he in February 1837 took Bourke himself to Port Phillip (which was reached on 4 March), and during this visit completed three charts which greatly facilitated the navigation of the port for many years. Later in the year, hearing from James Busby of internecine wars in New Zealand, Bourke sent off Hobson to protect British interests there, and asked him to report on the whole situation. To the resulting report, and to Bourke's high praise of both it and its author, Hobson owed his appointment on 13 July 1839 as lieutenant-governor of New Zealand under the governor of New South Wales—a post which on 3 May 1841 was converted into an independent governorship. His work in New

Zealand, which was of great value—including the conclusion of the famous treaty of Waitangi—is sufficiently described under NEW ZEALAND: it was unfortunately cut short by his death on 10 September 1842, following immediately on a paralytic stroke, but undoubtedly hastened by the strain of administration with an empty treasury and the vindictive opposition of the New Zealand Company. His epitaph was written by a Maori chief in an appeal to the Queen:—'My subject is a Governor for us the Maoris, and for the Pakeha in this island. .
Let him be a good man, as the Governor who has just died.'

Hoddle, ROBERT (1794-1881), born in London in August 1794, was made a military surveyor and draughtsman when only 18 years old, and employed in the trigonometrical survey of Britain. In 1817 he went on half-pay, and in 1821 proceeded to the Cape Colony as assistant engineer and was employed there on military surveys. In the hope of bettering his position he moved in 1823 to New South Wales, where under the rule of Sir Thomas Brisbane surveyors were much needed, and on 9 September was appointed at Oxley's request assistant surveyor in the Sydney office. Oxley, who was just starting on his famous journey to Port Curtis (during which he discovered the Brisbane River), sent Hoddle on 26 September to survey the newly discovered Bell's line of road over the Blue Mountains north of the Grose valley, a task which was completed by 11 November. During 1824 he was at work for the most part in the Goulburn and Bathurst districts, but accompanied Oxley—who had a high opinion of him—to Moreton Bay in September-October and surveyed and mapped the shores of the bay. For the next twelve years he worked steadily in one or other of the districts then being settled west and south of Sydney, laying out the townships of Liverpool (1827), Campbelltown (1827), and Goulburn (1832). On 1 July 1826 Darling made him assistant surveyor on the parliamentary establishment, and three weeks later eulogized him as 'one of the most competent men in the department'—an opinion shared by Oxley. On 7 August 1828, being then the senior assistant in the office, he was made acting deputy surveyor-general, and on 28 October was given the definite status of surveyor—which apparently made the acting appointment unnecessary; this was fortunate, because in April 1829 the colonial office refused to confirm it, and sent out S. A. Perry (q.v.) to fill the post. The decision is unexplained, but may be due to the fact that Hoddle was a protégé of a Whig nobleman, Lord Frederick Cavendish, and therefore unacceptable to the Tory minister of the time. The work by which he is chiefly remembered is the definitive laying out in 1837 of the township at Melbourne. On 3 March of that year Bourke made him senior surveyor at Port Phillip, and on 1 May gave him charge of the town site: on 1 June, by Lonsdale's orders, he acted as auctioneer at the first land-sale there. He had already (on 7 May) been made a commissioner of crown lands for New South Wales. The rest of his life he spent in the Port Phillip district. When Victoria was separated from the parent colony, Hoddle on 15 July 1851 was made its first surveyor-general: but in 1856 he retired from active service, and died at Melbourne on 23 October 1881.

Hodgkinson, W. O. See EXPLORATION BY LAND.

Hodgson, SIR ARTHUR (1818-1902), born at Rickmansworth in Hertfordshire on 29 June 1818, was sent to Eton when ten years old, but left it to join the navy as a midshipman (1833-7) in H.M.S. *Canopus,* left the service to spend a year at Cambridge, and in December 1838 migrated to New South Wales, where he was soon joined by his brother Pemberton Hodgson. In 1839, according to H. S. Russell (*Genesis of Queensland*), he owned Cashiobury station in New England, but sold it in 1840 and, on the advice of Patrick Leslie (the pioneer of the Darling Downs) travelled his stock to the Downs through Cunningham's Gap and took up a station near Toowoomba which he named Etonvale. In July 1856 he was appointed general superintendent of the Australian Agricultural Company (q.v.), and in 1858 was elected by the constituency of Clarence and Darling Downs to the New South Wales legislative assembly, becoming in 1859—when Queensland was made a separate colony, and his old constituency disappeared—member for Newcastle. In 1861 he entered the Queensland assembly as member for the Warrego, during the same year resigning his position with the Australian Agricultural Company and returning to the management of his own properties. In 1868 he joined the Mackenzie ministry, just before its fall, as minister for public works (10 September to 25 November), and was colonial secretary in the Lilley ministry which followed (28 January to 10 November 1869); he resigned in order to visit England, and in 1874 settled at Clopton near Stratford-on-Avon and spent the rest of his life as a territorial magnate. He died on 24 December 1902.

From first to last Hodgson was a squatter, with squatting interests at heart. When the southern colonies were in the thick of the anti-transportation agitation, he led a Darling Downs movement for the separation of Moreton Bay and its northern districts and the admission of 'exiles' to provide labour for the pastoralists, and came into collision with Dr. Lang thereanent; in 1854, indeed, the rivals contested an election for the county of Stanley (i.e. the Brisbane district) and Hodgson was elected, but was unseated by the elections and qualifications committee of the assembly. He favoured the establishment of a colonial peerage, and opposed the later and successful movement for Queensland separation. But as a representative of his colony in Europe he was in the right place, and did good work as commissioner at the London international exhibition of 1862, the Paris exhibitions of 1867 and 1878, and the Vienna exhibition of 1874. (C.M.G., 1878; K.C.M.G., 1886.)

His brother CHRISTOPHER PEMBERTON HODGSON spent some years at Etonvale, and was a member of Leichhardt's first expedition (1844-5), but at Leichhardt's request returned to Brisbane about a month after starting, as provisions were running short and the party's numbers had to be reduced. As a rumour reached Sydney that the expedition had been massacred, Hodgson in July 1845 started with a relief party to ascertain the truth, and followed Leichhardt's tracks for seven weeks through scrub and ranges into open plain country, returning with the assurance that the massacre story was baseless. Hodgson, who was apparently of a type unsuited to the colonial life of those days, then returned to England, and published his *Reminiscences of Australia* (London, 1846).

Holder, Sir Frederick William (1850-1909), born at Happy Valley in South Australia on 12 May 1850 and educated at St. Peter's College, Adelaide, became a state schoolmaster under the education department and afterwards editor and proprietor of the *Burra Record*. In April 1887 he was elected to the legislative assembly for Burra, and held the seat till 1901. In 1887 he was a member of the royal commission on the land laws; in 1888 he was made chairman of the barrier trade committee, and in 1890 chairman of the royal commission on intercolonial free trade. In 1889-90 he was treasurer in the Cockburn ministry, then became leader of the opposition, and on 21 June 1892 formed a short-lived ministry of his own. In 1893 he joined his former opponent C. C. Kingston as commissioner of public works (June 1893 to April 1894) and treasurer (April 1894 to December 1899). On 1 December 1899 the Kingston ministry was defeated, but within eight days Holder had formed his second administration, which lasted from 8 December 1899 to 15 May 1901. He took a prominent part in the movement for federation, and was a member of the 1897-8 convention. In May 1901 he was elected to represent South Australia in the federal parliament, and was unanimously elected speaker of the house of representatives, holding the position till his death. He served in the volunteer military forces from 1858 to 1899.

His death was tragic. During the stormy sessions of the house that followed the 'fusion' of 1909 between the parties led by Alfred Deakin and Joseph Cook, which ousted the Labour ministry from office, Holder spent weary and troubled hours in the chair attempting to control the frequent outbursts of political passion. Early in the morning of 23 July, the house having gone into committee during an all-night sitting, he was resting on a back bench when a storm of greater fury than usual threw the house into confusion; struggling to his feet in order to take the chair again if summoned, he fell in a fit and died almost immediately. The house, shocked beyond measure, adjourned at once, and at later sessions kept within bounds. (K.C.M.G., 1902.)

Holroyd, Arthur Todd (1806-1887), born in London on 1 December 1806 and educated at Ripon, Christ's College, Cambridge (M.B., 1832) and the university of Edinburgh (M.B., 1830), abandoned medicine after a year's practice in London and entered Lincoln's Inn as a law-student. The years from 1835 to 1838 he spent mainly in travel through Egypt, the Sudan, and Syria, which resulted in a spirited protest against the operations of the Egyptian slave-trade; in 1841 he was called to the bar, in 1843 migrated to New Zealand, and in 1845 came to Sydney, and was admitted to the local bar in October of that year. Taking up politics, he represented Bathurst and Carcoar in the legislative council from 1851 to 1856, was re-elected by the same constituency to the new assembly in 1856-7 (during which time he was its chairman of committees), and after a short absence re-entered the assembly in 1861 as member for Parramatta. In the Martin ministry of 1863-5 he was minister for public works, resigning after an unsuccessful attack on his administration, and taking the mastership in equity (1866) and in lunacy (1879). During the latter year he acted for some time as a judge of the supreme court. Apart from his profession he was mainly interested in scientific matters, being a fellow of the London Zoological Society from its foundation in 1826, of the Linnean Society from 1829, and of the Royal Geographical Society from 1849. He died in Sydney on 15 June 1887.

Holroyd, Sir Edward Dundas (1828-1916), grandson of Sir G. S. Holroyd, a distinguished judge of the king's bench, was born at Wimbledon in Surrey on 25 January 1828, educated at Winchester and Trinity College, Cambridge (B.A., 1851; M.A., 1854), and called to the English bar on 6 June 1855. After three years' practice in London he migrated to Victoria in 1859, was admitted immediately to the Victorian, and in 1867 to the Tasmanian, bar, built up a successful practice on the equity side, took silk in 1879, and in 1881 succeeded Wilberforce Stephen as puisne judge of the Victorian supreme court. He retired from the bench in 1906 and died at St. Kilda on 5 January 1916. (Kt. Bach., 1903.)

Holt, Joseph (1756-1826), born in 1756 in county Wicklow, Ireland, in 1782 took a farm in the parish of Dirrelossery, and was appointed to several minor public offices in Wicklow and Wexford. He was a Protestant, and had no sympathy with the rebellion of 1798 until his landlord (with whom he had quarrelled) denounced him as among the disaffected, proceeded to his house with a detachment of yeomanry, and burnt it during his absence. Resentful and indignant, Holt in May 1798 joined the rebels, and for more than six months conducted a successful guerilla campaign within 30 miles of Dublin. Time, however, wore down the rebel army, and Holt with a price upon his head was a fugitive in the Wicklow mountains; he surrendered on 10 November and was sentenced to transportation to New South Wales. His enemies said that easy terms were granted him in return for information supplied to the Castle authorities, but the only justification for this assertion is that after being sentenced, and while awaiting transportation, he revealed the existence of a conspiracy of United Irishmen in the neighbourhood of Cork; this he afterwards denied, but evidence found among Lord Castlereagh's correspondence proves it. Accompanied by his wife and family (except a daughter who was left with friends in Ireland) Holt sailed in the *Minerva* on 24 August 1799 and arrived in New South Wales on 11 January 1800; among his fellow-prisoners were two captains in the British army (Alcock and St. Ledger), Henry Fulton, a Church of England clergyman, and Father Harold, a Roman Catholic priest, all of whom were implicated in the rebellion. William Cox, paymaster of the New South Wales Corps and founder of a well-known Sydney family, travelled in the same vessel, and through his intervention the rebels were treated with more consideration than the other prisoners.

On arrival Cox obtained permission to take Holt into his service as a farm superintendent, but the prisoner indignantly refused, considering himself merely an exile, and not in any way at the disposal of the government—a view in which Hunter coincided. Later on, however, Holt found that to live he must eat, and to eat, work, and on 22 January 1800 became manager of Cox's Brush Farm, near Ryde. On 5 September he was arrested under suspicion of being concerned in a conspiracy of Irish prisoners, but nothing was proved against him, and King restored him to liberty; he returned to the farm, and by good management considerably improved

the estate, which Cox on his advice enlarged by the purchase of land from adjoining owners. Holt also bought land for himself; his first farm was about three-quarters of a mile from the Cox estate, and later on he bought adjoining property. On 5 March 1804 another attempt at rebellion was made, which culminated in a fight on Castle Hill near Parramatta; the rebels were quickly put to flight, and 12 of their ringleaders subsequently hanged. Some of them falsely accused Holt of participation in the crime, and he was improperly committed to prison by Atkins the judge-advocate; always arrogant, he defied Atkins and all his works, and in May King exiled him to Norfolk Island. In November 1805 he was permitted to return to New South Wales, and embarked in the *Sydney*, which put in at the Derwent River in Tasmania on 2 December. Here he met Collins, who was friendly and asked him to report on the value of land along the Derwent; after three weeks' investigation he reported that, instead of 35 or 40 bushels to the acre, farmers would be lucky if they got 20, and even this yield could only be made fit for use with great difficulty, as it was infected with smut. Collins now asked Holt to take charge of the government farms, and he would have done so had not his wife (who had not been sent to Norfolk Island) preferred to remain in Sydney. He therefore returned to Port Jackson on 5 February 1806, and found his affairs in good order; but not long after his return he took it into his head to set up a still. He was caught and brought before Major Abbott, but was let off on bonds being entered into, and did not offend again.

During the Bligh mutiny he seems to have kept clear of both parties. On 1 January 1811 good conduct brought him a free pardon; he at once put up his farms for sale, secured a passage in the *Isabella*, and sailed for England on 4 December 1812—among his fellow passengers was Sir Henry Browne Hayes (q.v.). On 7 February 1813, when off the Falkland Islands, the ship struck a reef, and all on board were landed with difficulty on Eagle Island. Some of the crew went off in the long-boat to look for help, and at Buenos Ayres found H.M.S. *Nancy* which was despatched to the rescue. Meanwhile on 4 April the American brig *Nannen* put in at the island, and the castaways arranged with her master to take them off, in return for the wreck and what he could get out of it. On 12 May, just when the Americans were loading their vessel with the salved cargo, the *Nancy* arrived and, as Britain was then at war with the United States, made the *Nannen's* crew prisoners of war, and took them and the castaways to Rio de Janeiro. Holt arrived in Dublin on 5 April 1814, started a hotel, found it a losing investment, and at the end of a year gave it up, using what remained of his capital to build some houses. He died in poor circumstances in 1826 at the age of 71, regretting that he had left New South Wales.

The Memoirs of Joseph Holt, edited from the original MS. in the possession of Sir William Betham by T. Crofton Croker, and published by Colburn (London, 1838), is the best authority for his life.

Homalanthus, a small genus of the family Euphorbiaceae, containing two species, both indigenous to Australia and ranging from Victoria into northern Australia. *H. populifolius* is a tall shrub with large, almost triangular leaves, which often turn red. The diminutive, unisexual flowers are borne on slender spikes; capsule greyish-green, opening tardily; seeds enveloped in a fleshy coat (*arillus*). The shrub is known as 'native poplar,' from the shape of its leaves—which are, however, much larger than those of the European poplar. It is also called 'Bulli poison-bush,' and is reputed to be poisonous to stock, though feeding experiments with calves, covering a lengthy period, have been conducted without any injurious effects.

Honey-eaters, a family of perching birds (Meliphagidae), characteristic of the Australian region, to which it is confined. The numerous species range from Australia and Tasmania through the Papuan islands to Timor, Lombok, and Celebes, and eastwards to New Caledonia, New Zealand, and the Chatham, Samoan, and Hawaiian islands.

Members of the family vary in size from the little bloodbird, only about four inches long, to the wattle-birds, friar-birds and New Zealand parson-bird, which measure from 12 to 15 inches. In respect of coloration, though a large number are more or less brown or green, many are adorned with black, white, yellow, and red; several have brightly-coloured patches of bare skin on the head, or fleshy wattles on the cheeks. The bill varies greatly in length, being quite short in the blackcaps (*Melithreptus*) and long and slender in the spinebills (*Acanthorhynchus*); but it is always somewhat curved. The distinctive feature of the family is the protractile tongue; this is divided into two branches, each split up into numerous stiff horny fibres that form a brush. It is used for obtaining honey from flowers, as this forms the principal article of diet of many species; it is supplemented in most cases by insects, and in some by fruits.

Honey-eaters are generally lively birds, hopping and fluttering actively about flowering trees and bushes, or climbing among the twigs. Most of them utter melodious calls, but some of the larger species have distinctly harsh, discordant cries. A few are quite pleasing songsters. The nests are open, cup-shaped structures, placed in trees or bushes—usually in forks, but sometimes suspended by the rims. They are variously composed of grass or bark, often interwoven with cobwebs and lined with finer materials, hair or wool. The eggs, sometimes white, are usually somewhat pink or buff in ground-colour, and are almost invariably spotted with reddish-brown or grey.

About 70 species of honey-eaters occur in Australia and Tasmania. The majority are merely known as honey-eaters with some qualifying adjective, but the larger forms are called miners, friar-birds and wattle-birds. These are dealt with in separate articles. The remaining smaller forms, including the spinebills, are briefly dealt with below.

The genus *Melithreptus* includes seven species in Australia and Tasmania, and is also represented in New Guinea. It comprises greenish-yellow birds (often known as blackcaps) with black or dark grey heads and white underparts. Most of the species have a white stripe across the back of the head. The best-known is the White-naped Honey-eater (*M. lunu'atus*), a very common species throughout southern Australia. In northern and eastern Australia the White-throated Honey-eater (*M. albogularis*) takes its place; its Tasmanian representative is the Strong-billed Honey-eater (*M. val'idirostris*). The genus *Myzomela* includes the smallest honey-eaters, with long curved slender bills. A number of species occur in New Guinea, Malaysia, and the Pacific islands, five being found in Australia,

though only two extend into the southern portions of the continent. These are the Black Honey-eater (*M. nigra*) and the Sanguineous

White-naped Honey-eater (*Melithreptus lunulatus*).

Honey-eater or Bloodbird (*M. sanguineolenta*). The male of this species has the head and body

White-throated Honey-eater (*M. albogularis*).

bright scarlet, the wings and tail being black. It has a very pretty song.

The two species of *Acanthorhynchus*, a genus confined to southern Australia, are known as 'spinebills' on account of their long, slender, curved bills. *A. tenuirostris* occurs in south-eastern Australia and Tasmania, and *A. superciliosus* in the south-west. Both species have a crescent-shaped white band on the breast, surrounding a chestnut patch on the throat, which is especially distinct in the western species. *Glyciphila* is represented by four species in Australia, and extends to Timor, New Guinea and New Caledonia. The best-known Australian form is the Tawny-crowned Honey-eater (*G. melanops*), which frequents open, heathy situations throughout southern Australia and Tas-

Spinebill (*Acanthorhynchus tenuirostris*).

mania. The handsome Regent Honey-eater (*Zanthomiza phrygia*), the sole member of its genus, is peculiar to south-eastern Australia. It is black, with brilliant yellow patches in the wings and tail, many of the feathers on the back

Regent Honey-eater.

and shoulders also having golden edges. The cheeks are bare of feathers and covered with wart-like excrescences; hence it is often called warty-faced honey-eater. The little Brown Honey-eater (*Stigmatops indistincta*), the plainest in colour of all the Australian honey-eaters, is perhaps, the best songster of the family, its notes having a great resemblance to those of the reed warbler. It is common throughout the warmer

parts of Australia, though absent from the south-east corner.

Meliphaga (better known as *Ptilotis*) is by far the largest genus in the family, comprising some 40 species. These are found throughout the Papuan and Polynesian islands, and 23 occur in Australia and Tasmania. They are mainly dull green above and dull yellow below, usually with a tuft of stiff white or yellow feathers on the cheeks, and often with some black on the head and brown streaks below. Many of the species are very similar, and in the bush are only to be distinguished by experts. Some of the best-known are Lewin's Honey-eater (*M. lewini*), which commemorates the first writer to publish a book on Australian birds in Australia; the Singing Honey-eater (*M. sonora*), whose name is not very appropriate, as the loud, mellow notes which it utters hardly constitute a song; the Yellow-faced Honey-eater (*M. chrysops*), often called the 'chick-up' in imitation of its call; the Yellow-plumed Honey-eater (*M. ornata*), the White-eared Honey-eater (*M. leucotis*), the Wattle-cheeked Honey-eater (*M. cratitia*) and the White-plumed Honey-eater (*M. penicillata*), generally called 'greenie' in Victoria, and also known as 'chickoowee' from its note.

The genus *Meliornis* contains three species confined to southern Australia and Tasmania, all marked with black and white on the head and breast, and with a good deal of yellow in the wings. The most plentiful is the New Holland Honey-eater or Yellow Wings (*M. novae-hollandiae*), the White-cheeked Honey-eater (*M. nigra*) is very similar, but has more white on the head and is not so common. The third species (*M. pyrrhoptera*) derives its name of Crescent Honey-eater from the black band on its breast. It is also called 'egypt' in imitation of its notes.

Hoppers. See HEMIPTERA.

Hops were first grown in Australia by James Squires, who in 1806 or 1807 produced a few pounds upon five acres of land near Ryde in New South Wales, and by 1812 had increased the yield to 1500 lb. For this he was presented by Macquarie with a cow. With the exception of a plantation made a little later near George-street-west in Sydney, and a few others of no great size, no further efforts were made, and hop-growing never made headway in the mother-colony. At one time it was expected that hop production would become an important industry in Victoria and in 1883 an area of 1758 acres was planted; but this dwindled to 307 acres in 1901-2 and 87 acres in 1917. In Tasmania, however, the industry flourished for many years, mainly along the Derwent River from New Norfolk upwards. From 1870 onwards the production fell not far short of a million lb. annually, but during the early eighties high prices stimulated planting to such an extent that over-production brought them down with a run and nearly ruined the industry. In 1900 the area under hops was 624 acres and the production 696,679 lb. Hop-growing in the Commonwealth is now practically confined to Tasmania and some of the cooler districts of Victoria. The total area planted for the season 1922-3 was 1741 acres, 1545 in Tasmania and 194 in Victoria. During 1922-3 imports exceeded exports by 727,276 lb., with a value of £51,497.

W. S. C.

Horn, WILLIAM AUSTIN (1841-1922), born in the Snowy River district of New South Wales on 24 February 1841, taken by his parents to South Australia in 1852, and educated at St. Peter's College, Adelaide, in 1861 took up pastoral life, and almost immediately found himself enriched by a partnership in the famous Moonta copper-mine; the ride to Adelaide from beyond Wallaroo—about 160 miles in 22 hours—by which he secured the mine is still remembered. He soon became well known in the mining world, and frequently visited England to procure capital for his ventures; during one of these visits, in 1872, he matriculated at Worcester College, Oxford, but did not complete his studies there, returning to Australia in 1874. In the early eighties he took a prominent part in opening up the Broken Hill silver-lead field. In 1887 he was sent to the South Australian legislature as member for Flinders, and held the seat until 1893. In the following year (1894) he fitted out an expedition to investigate the country between Oodnadatta and the Macdonnell ranges; the four volumes in which the results of this expedition are embodied contain a mass of geological, biological, botanical, and ethnological detail. In 1898 he left Australia and resided for the rest of his life in England, where he died on 22 December 1922. His benefactions to the city of Adelaide, which included some valuable statuary and an important collection of 11,000 ancient coins, were considerable.

Horne, RICHARD HENRY (1803-1884), was born in London on 1 January 1803 and educated at Sandhurst in order to enter the East India Company's service; failing to obtain entrance, however, he began an adventurous career by enlisting in the Mexican navy during that country's revolutionary war against Spain, and continued it with travels among the North American Indian tribes and a shipwreck in the Gulf of St. Lawrence. His return to England in a timber-carrying vessel gave him the added experiences of a mutiny and a fire aboard ship. From 1828 to 1852 he made new adventures in English literature, diversified by a friendship with Elizabeth Barrett Browning; among them was the publication of the epic *Orion* in ten books, the first three editions of which were issued at a farthing—eight more followed. In 1852 he came with William Howitt to Australia, and held various positions in the public service, beginning as commander of a gold-escort, and passing on to be successively a commissioner of crown lands, a territorial magistrate, and a member of the board of water supply which constructed the Yan Yean reservoir. In 1869 he returned to England, where in 1874 the Disraeli ministry granted him a civil list pension. After another period of miscellaneous authorship he died at Margate on 13 March 1884. While in Australia Horne wrote nothing of literary value. His reputation, however, and his strength of character made him a notable figure among Melbourne writers and critics of the sixties; probably the one debt Australia owes him is for his recognition in 1868 of Henry Kendall as her best poet. The name 'Hengist,'

by which he is often known he adopted in place of 'Henry' as a compliment to a Mr. Hengist whose acquaintance he made in the Victorian bush.

Horse Mackerel. See YELLOWTAIL and MACKERELS.

Horses. The First Fleet brought from the Cape of Good Hope one stallion, three mares, one colt and two fillies. The stallion and two mares were reckoned Government property; the others belonged to Phillip. In 1795 33 more were landed from the Cape, and by 1796 the records show 14 horses (including mares) as government property and 43 as belonging to the officers of the Corps; other settlers had none. Seven more mares arrived from the Cape in 1797, and another eight in 1800, and by that time the stock had increased to 203. King in 1802 reported that, 'being mostly of the Cape breed,' they were not very useful, and chiefly employed in carting and ploughing. In October of that year a fine stallion was sent from England to George Johnston (q.v.), and did ten years' useful service before dying. The next two years saw several such importations, nearly all from India. Robert Campbell brought in an Arab stallion in February 1803; King bought an English horse from Barrallier in August; in April 1804 a second Arab arrived, which King promptly bought and re-sold to the government; and in June six horses and a stallion were shipped from Calcutta, and it became possible to hope that the poor qualities of the Cape breed might gradually be neutralized. In 1805 the number of horses was 494, of which only 36 were government property and 72 belonged to officers of the Corps. But in 1806 the price of a horse was still high—'from £100 to £150' reported Johnson, 'for a common mare from 13½ hands to 15 hands high.' This evil soon cured itself. When Macquarie arrived in 1810 he found 1134 horses; when he left, there were 4564, and the price of a good cart-horse was no more than £10 or £15. There was even a small export trade to Batavia and the East Indies. Sir T. Brisbane imported a stallion whose fame was still great 50 years later: 'he was a beautiful bay' said John Lackey in 1873, 'and stood little more than 14 hands, with perfect symmetry combined with length, breadth, depth and muscle sufficient to furnish the mounted police corps with troop-horses that could scarcely be outweighted or over-ridden.'

A writer in 1826 thus summed up the then situation: 'There is, properly speaking, no breed of good draught-horses in the colony. The majority of the horses may be described of the nag kind, not very sightly in appearance, being narrow and sharp-backed, fall off much about the rump to the tail, low-necked and large headed. . . . they are, however, subject to few diseases and capable of enduring great fatigue, and will perform long journeys on indifferent keep much better than any horses in England. There is a breed of small Galloways, derived from crosses with the Acheen breed of ponies. They are very hardy and serviceable, and some of them handsome. Within the last few years some very good thoroughbred horses have been introduced from India and England. One of the best of these was Mr. Browne's Arabian horse *Model* from Calcutta; the best cross-bred horses now in the colony are derived from this very fine specimen of the Oriental breed. A cross-bred horse of his getting has been sold for 200 guineas for exportation to India. . . Some stallions and mares of the English and Flemish cart breeds have been lately introduced. . . . .'

In 1826 the Australian Agricultural Company (q.v.), soon after beginning operations at Gloucester and Stroud, imported some excellent types of Arab, Welsh, and English breeds. Their saddle-horses were famed far and wide, being admirable stock-horses for the rough and mountainous watershed of the Hunter; their power of endurance was almost incredible. At a sale of A.A. Company's stock at Maitland in 1840 37 mares (a few with foals) fetched from £35 to £95; 3 geldings, £34 to £51; 1 Clydesdale stallion, £175; 3 Welsh pony stallions an average of £53.

A brisk export of horses to India for military purposes grew up in early days, and in later years the Australian type (coming chiefly from New South Wales) was distinguished—and still is—as the 'Waler.' As pastoral settlement extended, however, and the need of horses to maintain it became greater, deterioration of breed set in. The services of thoroughbred sires became unattainable or expensive; colts, often of the most indifferent descriptions, were used in their stead, and ran loose with little mobs of mares and fillies about the settlers' homesteads. Such inferior stock in the early days of the Port Phillip settlement fetched £70, £80, and £100, and as a consequence the production of them was at once pushed to the utmost. The crisis of 1841-2 diminished the need, and abolished these fictitious values, and by the end of 1843 it was possible to buy three 'weeds' for the price of one saddle. From that time forward, while poor stock was much used (as it still is), high prices were given only for good qualities; and in 1873 Sir Hercules Robinson was able to tell a meeting of horse-breeders: —'I think it may be said of Australian horses generally that they are a great deal better than they look. . . . .Racehorses bred in New South Wales will compare very favourably with the best class of English thoroughbreds. . . . I think that the heavy draught cart-horses which I have seen are equal to anything I have seen in the world. What remains is just the great bulk of the light draught and saddle horses scattered over the country. They do not compare favourably in either appearance or condition with the same classes of horses in England, but then they are brought up in a totally different way. . . . . The only animals in which we are deficient are those which I may style fancy animals—horses which are produced under exceptional conditions, and at a very considerable cost, described as well-bred, fast-going, weight-carrying hunters . . . . An animal of that description would fetch £200 at home. We have not got it here, because there is no demand for it; if they are produced, they will not sell at a price that would pay . . . . '

W. H. L. Ranken says:— . . . . 'The ordinary horse of the country may be described as a light, hardy horse; he has a wonderful constitution, splendid feet, great endurance and very good temper. He is generally small, but there are many different types. The Arab, with short saddle-back, fine, broad forehead and grey colour, was not so rare a few years ago, but is becoming less common now than the higher, long-faced English horse, who sometimes is too heavy by strains of draught stock and sometimes very ragged behind by a cross with the Valparaiso horse. The last animal, with his weak

frame and bad quarters, did a great deal of harm to the breed of horses in the colony. His endurance and constitution the bush horse probably got with his Arab blood; but the climate of the country has done a great deal for him, as the horse, like the sheep, loves a dry climate. Of all bush horses the stock-horse is the best type. He is ridden all day, and turned out at night without brushing, cleaning, or clothing. He is shown the water, hobbled, and left to take care of himself for the night; at home he is put into a paddock as his saddle is taken off. In snow, or rain, or mosquitoes—in any season of any climate—he finds his only feed in the grass of the forest or plain. Next day he is brought up at sunrise, and ridden again. Day after day, for weeks of light work, or consecutive days of hard galloping after stock, he continues this life. He may have never been shod nor stabled, nor have tasted corn in his life. He will travel along the hot, dusty roads, doing his two (sometimes his three) hundred miles in a week. A hundred miles and more in twenty-four hours have often been accomplished by a bush horse upon grass food, without breaking his constitution or hurting his feet; for the climate supports his vigour, and there are no metal roads in the bush.'

There is a considerable difference in the style and make of horses bred in the several States, ranging from the light types of northern and tropical Australia to the heavier classes of the temperate climates. This difference is, no doubt, to a large extent the result of climate and surroundings. In Victoria really heavy draught-horses are raised; 'the smaller the holdings, the heavier the draught horse' seems to be a general rule. The draught-horses of New South Wales are on the whole distinctly smaller and lighter than those of Victoria, and Queensland draught-horses are lighter still. Some writers attribute this to the greater area of holdings in the northern States. Where greater distances, they say, must be travelled by the cart-horse or wagon-horse, more activity and less weight are essential.

Partly on account of the suitable climate, partly because pastoral work in these days needs more horses than does agricultural work, Queensland has for some years taken the lead of the other States in horse-breeding, and is responsible for nearly 31 per cent of the Commonwealth total. The war encouraged breeders, and 1917-8 proved the record years for number. It also temporarily increased exports, as the figures given below will show; but, while they are described in official statistics as 'exclusive of shipments for military purposes,' this only means that they do not include horses actually shipped for the use of Australian regiments—most of them went to India for use in the

Number of Horses in Commonwealth.

1922	2,390,460

Indian army. Apart from New South Wales and Queensland, which have for many years fought for the lead in production and held about 58 per cent of the Commonwealth total between them, the output of the several States has been singularly uniform; Victoria has had about 21 per cent, South Australia 11, Western Australia 7, Tasmania and the Northern Territory about 1½ per cent each.

The great decrease in exportation since the war is partly due to lack of care among breeders. Sir H. Chauvel (q.v.) reported in 1921 that less than 3 per cent of Australian horses were up to cavalry or artillery standard; in 1924 he stated that the breeding of light cavalry horses 'had reached a dangerously low ebb,' and recommended government assistance to the industry. In 1925 a Horse Association was founded in New South Wales for the express purpose of improving the breeds and establishing a higher standard.

W.S.C.

Horton, WILLIAM (1800-1867), born at Louth in Lincolnshire in 1800, was in 1820 received into the Methodist ministry and in 1821 appointed to the Australian mission. He sailed in the *Brixton* with Samuel Leigh and William Walker as fellow-passengers; Leigh had visited England in the interests of a proposed mission to New Zealand, and Walker was appointed for work among the aborigines. Reaching Hobart in August 1821, Horton found that the small Methodist body lacked a minister, and determined to stay there. Sorell, who favoured all religious bodies, gave the Methodists a grant of land for a chapel, and leave to perform services in the government school-houses, but recommended Horton to give special attention to districts where the population was on the increase and could not be supplied with official chaplains—he instanced Macquarie Harbour, and offered to build a house for the missionary if Horton could provide one. Hobart, however, was as much as Horton could look after, and there he laid the foundation of the first Methodist chapel, though it was not opened until 1826. In October 1823 he was transferred to Sydney, and given charge of the Windsor district, moving to Sydney in 1826 and returning to England in February 1829. For the next 23 years he ministered at various stations in England and Scotland, retired from active work in 1852, and died in London on 18 June 1867.—His cousin Samuel Horton, who migrated to Tasmania in 1823, settled at Ross, and in 1852 founded the Methodist training institution known as Horton College.

Hospitals. In each State capital there is at least one large general hospital, and most country centres possess smaller ones. The chief cities also support hospitals designed especially for women, children, patients with infectious diseases, etc. Private hospitals are numerous, but cannot be dealt with here. The financial basis of most of the large general hospitals—which (except for a few institutions maintained wholly by government) are supported partly by endowment and voluntary con-

tributions and partly by government grants—has been at times so insecure as to hamper their work. Recently efforts have been made in some States to remedy this by legislation. In South Australia an act of 1920 empowers the inspector-general of hospitals to make levies on local government authorities for hospital support. In Victoria a central authority was constituted in 1922 to control the distribution of government subsidies, etc. The Western Australian government in 1921 appointed a commission to inquire into the subject. In New South Wales and Queensland no comprehensive scheme of hospital administration has been enforced by legislation, existing acts covering the activities of general hospitals merely providing for their incorporation, for the election of members of committees, etc.

Sydney Hospital.—Until 1848 the Sydney Hospital was financed and controlled by the British authorities dealing with transportation. The First Fleet carried a complete medical staff, from which a principal surgeon (John White, q.v.), three assistant surgeons (William Balmain, Thomas Arndell, and Dennis Considen) and a junior (John Irving) were appointed a medical staff for the colony. Early in February 1788 work was begun on a hospital building on the west side of Sydney Cove; but its accommodation was inadequate, and after the arrival of the second fleet it was found necessary to pitch between 90 and 100 tents in the grounds. Of comfort for the sick there was none. Under the direction of Governor Hunter and William Balmain (who had taken over White's duties in 1794) the first hospital was pulled down, and a new one erected on a stone foundation near the site of the present Argyle Cut; a store and dispensary were added. The principal surgeon was in charge, with one assistant surgeon and a staff of 20 convicts in Sydney, one surgeon at Norfolk Island and one at Parramatta. In 1805 Thomas Jamison succeeded Balmain as principal surgeon. On his arrival in 1810 Governor Macquarie declared the building of a new general hospital an absolute necessity. Seven acres of land were chosen 'on the elevated ridge of vacant land south of Government House' along which Macquarie-street was opened. In order to relieve the government of this additional burden Macquarie entered into a curious agreement with the contractors (Garnham Blaxcell and Alexander Riley), by which their compensation was to take the form of a monopoly for the importation of 45,000 gallons of spirits during the following three years; minor concessions were allowed, the monopoly was extended to the end of 1814, and the hospital, occupied in 1816, was completed in July of the following year.

D'Arcy Wentworth (who had been acting principal surgeon since 1809 in the absence of Thomas Jamison, and succeeded to the permanent position in 1811 on Jamison's death) became a party to the contract, with Macquarie's permission, after it was accepted. When the hospital was opened he naturally took charge of it, with William Redfern as assistant surgeon, but during his term of office (1816-19) chaos reigned in hospital administration; overcrowding was frequent, there was no one in charge of the wards between sundown and 6 a.m., and the patients were allowed to do their own cooking and washing in the wards. James Bowman, who took over control on 25 October 1819, prohibited these practices and secured some measure of order. Nurses and wardsmen were required to sleep on the premises, Bowman himself made a daily inspection of the patients, initiated the classification of diseases, and made investigations into the medicinal properties of Australian plants. In 1829, when Bowman was appointed inspector of colonial hospitals, James Mitchell (q.v.)—who had been mainly responsible for the work at Sydney hospital since 1825—was promoted surgeon in charge.

In 1836 the military and civil medical establishments, both in New South Wales and Tasmania, were combined on a military basis, a deputy-inspector-general of hospitals—John Vaughan Thompson—being appointed. Thompson was devoid of the tact necessary to conciliate civil and military interests, and issued ill-advised orders to the colonial surgeons. It was not long before he and Mitchell were at loggerheads over the management of the Sydney hospital, and in September 1837 Mitchell was dismissed the service. His successor at the hospital was more amenable to control, and harmony was completely restored when in 1844 Thompson was superseded by William Dawson. While under British control, the hospital was mainly used for sick convicts, but in the forties free paupers were admitted, a charge on their account being made against the colonial government.

On the cessation of transportation to the eastern mainland the British government being no longer obliged to maintain convict hospitals, gradually reduced the medical establishments in New South Wales. A hospital had been established at Windsor in or about 1812, a special building being erected in 1820; similar institutions were founded at Bathurst in 1824, at Liverpool in 1828 (Darling proposed to make this the principal hospital in the colony) and at Goulburn in 1834; all these (except that at Liverpool) were closed in 1842, and on 1 January 1843 the only medical establishments under government control were at Sydney, Parramatta, Liverpool, Newcastle, Port Macquarie and Moreton Bay. The two last mentioned were insignificant, their combined staffs numbering 13 only. The three country hospitals that had been closed were reopened as civilian institutions under private control, Goulburn and Bathurst at once (in 1842), and Windsor by the Hawkesbury benevolent society in 1846. The main hospital at Sydney was closed (as a government institution) in 1848, but had been dismembered many years earlier. At the end of 1828 Darling appropriated the north wing of the building for the use of the legislative council—it still forms the nucleus of the State parliament house; the south wing, after being used for some time as an ordnance store, was in 1843 transferred to the Sydney dispensary, an institution founded in 1826 for the care of the free pauper sick and maintained by public subscriptions until 1835, when it was subsidized from colonial funds. In 1848 the main building of the hospital was transferred from the British to the colonial government, which at once handed it over to the dispensary. The British medical officers were transferred to the medical staff in Tasmania, and 20 tons of hospital stores were sent to that colony.

As a civilian institution the hospital was managed by a board of directors which included members of parliament, the mayor of Sydney, and persons elected by annual subscribers and by donors of various sums from £20 upwards (including congregations which were represented by their ministers, legators represented by their executors, and societies, which could nominate their representatives). In all there were 31 members of the board, including two

secretaries and three vice-presidents. The administration by this heterogeneous body was very defective, and some improvements were made in 1865; in 1867 it was decided to appoint a superintendent with control of all employees and general oversight of all the details of management. In March 1868, therefore, there arrived in Sydney a trained nursing staff, consisting of a lady superintendent (Lucy Osburn) and five sisters who had been selected, at the request of Henry Parkes, by Florence Nightingale, for service in Sydney. The new staff had much opposition to contend with in its attempts to better the conditions of hospital reorganization and management; there was antagonism between the medical and nursing staffs, and confusion as to the authority of the manager and the lady superintendent. This difficulty was remedied in 1875 by the appointment of a paid secretary, who attended only to the external affairs of the hospital. The hospital became a training school for nurses, and the old illiterate women attendants were dispensed with.

The nursing system introduced by Lucy Osburn was the one aspect of hospital administration reported on favourably by the royal commission appointed on 8 April 1873 to inquire into the activities of the Sydney infirmary and orphan schools. Its report resulted in the Sydney Hospital act, passed on 15 November 1881, by which the institution was incorporated and its administration vested in a board of directors; at the same time its title was changed to Sydney Hospital. During the eighties physicians began to specialize, and various departments were opened, mainly for the treatment of out-patients.

A new building was opened in August 1894 at a cost (according to the official balance-sheet) of £93,601, of which sum £54,500 was provided by the government and £39,101 by subscription. On 20 October 1909 a clinical school for medical students of the university of Sydney was inaugurated. In 1924 the hospital had 362 beds and a resident medical staff of 29.

The Royal Prince Alfred Hospital, in Sydney, was founded to commemorate the gratification of the people of New South Wales at the recovery of the Duke of Edinburgh from the wound inflicted by an assassin at Clontarf in 1868. Long controversies about its site and its governing body delayed the erection of the building; but it was finally agreed that it should be placed on about 13 acres in the university area, that the hospital should be a general one for the treatment of patients without distinction, that the senate of the university should co-operate with the directors in electing the medical staff, and that the university should be allowed to establish a medical school in connection with the hospital. In 1873 an act incorporating the hospital was passed; in 1876 the foundation-stone was laid, but work was delayed until in 1878 the government gave further assistance. On 25 September 1882 the hospital was opened, providing accommodation for 146 patients. Most of the work up to this time had fallen on the shoulders of Sir Alfred Roberts who had studied hospital construction in Europe: he became honorary secretary of the hospital board and, with a brief interregnum between 1885 and 1887, practically ruled the hospital up to the time of his death in 1898. Following the arrival in 1883 of Thomas Peter Anderson Stuart (q.v.) arrangements were made for a course of hospital clinical study in connection with the university curriculum. On 27 August 1890 was laid the foundation-stone of a much-needed nurses' home, with accommodation for 50 nurses; the enlargement of the hospital and the consequent increase in the number of patients soon made this inadequate, and in 1911 additions to the nurses' home were built by the government providing accommodation in all for 216 persons. In 1902 work was commenced on two new pavilions intended as a state memorial to Queen Victoria; these were opened in 1904, modern equipment being gradually installed later, as the wards were opened for use.

In 1906 a department of medical gymnastics was opened for the treatment of physical deformities by Swedish drill and massage, the hospital thus becoming the first clinical school for massage students, who in 1918-19 numbered 92. Clinics have been established for the treatment of tuberculosis and venereal and dental diseases. During the war practically the whole resources of the hospital were placed at the disposal of the Commonwealth government for the treatment of returned wounded soldiers, many university graduates gaining valuable hospital experience here before taking up military duties. Two wards of 40 beds each are still set apart for military cases. From 1901 onwards until his death in 1920 Anderson Stuart was the ruling spirit of the hospital, and practically all the improvements in it were either devised by him or carried out under his personal supervision. In 1916 a social service department was established in connection with the hospital, which assists the families of poor patients and in other ways relieves the patients from worry and secures for them convalescent and other treatment when they leave the hospital. In 1923 was established the *Royal Prince Alfred Gazette*, the first hospital magazine in Australia.

The Royal Prince Alfred Hospital (the title 'Royal' was added by permission in 1903) is the largest endowed metropolitan hospital in Australia, having in 1924 520 beds and a resident medical staff of 29.

The Coast Hospital at Little Bay, New South Wales, is a general hospital with special provision for patients suffering from infectious diseases, including a leper lazaret with 16 patients in 1924; it was established in 1881 by the government as a result of the refusal of the directors of the Sydney Infirmary to admit a large number of patients suffering from measles during the epidemic of 1880. It is maintained by government, and is under the control of the director-general of public health; in 1924 there was accommodation for 694 patients and a resident staff of 11 medical officers.

St. Vincent's Hospital, Sydney.—On 31 December 1838 five sisters of charity (two of whom had studied hospital work in Europe) arrived in Sydney from Ireland, and for some years worked among the women at Parramatta; but in 1857 they were installed in a building in Victoria-street, Darlinghurst, which was later used as a school. The present hospital was opened in 1870 and enlarged in 1886. In 1857 it had 13 in-patients and 81 out-patients; in 1924 there were 225 beds, 3300 in-patients, 42,100 out-patients, and 30 medical officers in attendance.

The Melbourne Hospital.—In November 1839 the superintendent of the Port Phillip district purchased a building to be used as a temporary hospital and police office; but the space devoted

to hospital purposes was inadequate, and in March 1841 a meeting of influential citizens affirmed the desirability of establishing a central general hospital. While subscriptions were being collected with some difficulty, a cottage was rented in Little Collins-street; a larger building in Bourke-street was subsequently used to meet the needs of the sick poor. After prolonged negotiations with the Sydney authorities a site in Lonsdale-street was finally granted for hospital purposes, on 20 March 1846 the foundation-stone was laid, and early in 1848 the new building (with 22 beds) was ready for occupation. Part of this is still preserved, though the hospital was rebuilt in 1910-14 with the aid of munificent donations (including £145,000 from the Edward Wilson estate and £20,000 from the estate of T. J. Sumner) and a government grant. Large bequests from John Linay and Francis Ormond have also aided its growth. The hospital has a normal capacity of 358 beds but in 1923 the average daily number of inmates was 398. It is the principal clinical school for medical students of the university of Melbourne, and is also the largest training-school for nurses in the State. Attached to the hospital is the Walter and Eliza Hall Institute of Research in Pathology and Medicine.

The need of a second hospital for the Melbourne district was felt in the early sixties, and was publicly called attention to in 1865, but difficulties about the site delayed any active measures until 1868, when the escape of the Duke of Edinburgh from assassination was adopted (as in Sydney) as a reason for erecting a memorial of thanksgiving. It was decided that the memorial should take the shape of a hospital; work on the building was begun in November, on a site in Commercial-road given by the municipality of Prahran, and the foundation-stone was laid on 6 March 1869 by the Duke himself, the hospital being named the *Alfred Hospital*. It was opened on 4 May 1871, with 110 beds; additional wards were provided for by a bequest of £12,000 from John Linay, and were opened in 1885. In 1880 the first training-school for nurses in Victoria was opened in connection with the hospital, and in 1888 it was affiliated with the university of Melbourne as a clinical school for medical students. In 1910 it was incorporated. In 1921 work was begun on an extensive building scheme, and since then a nurses' home of 120 rooms, a surgical wing with accommodation for 80 beds, two operating theatres, a pathological block, enlargements to the electrical pavilion, and some administrative buildings have been erected. In addition to this the whole of the hospital has been practically remodelled since the beginning of 1921. It has now (1925) accommodation for 300 adult beds and 40 children's cots. There are 67 honorary medical officers in attendance, and a medical superintendent and 16 other resident medical officers.

The *Homoeopathic Hospital* at Melbourne originated from a meeting held in Melbourne on 30 October 1869, at which it was decided to establish a homoeopathic dispensary. This was opened in Collins-street, and the managing committee included the chief justice (W. F. Stawell) and the dean of Melbourne. In 1876 the dispensary was turned into a hospital and moved to Spring-street, and in 1882 the foundation-stone of the present building in St. Kilda-road was laid by Lord Normanby, then governor of the colony. The southern wing was built and equipped at the expense of James L. Hosie in 1890. A training-school for nurses is attached to the hospital. Provision will be made for 140 beds when the new building, now in course of construction, is completed.

The *Victorian Eye and Ear Hospital*, opened as a private institution in 1863 by Andrew S. Gray, was converted into a public hospital in 1868, and in 1870 amalgamated with an already existing 'Ophthalmic and Orthopaedic Institution' conducted by Dr. Aubrey Bowen. In 1881 it was moved to its present site on Eastern Hill. It has accommodation for 94 in-patients. Being the only hospital in Australia dealing exclusively with disorders and diseases of the eye, ear, nose, and throat, it is attended by patients from all the States of the Commonwealth. The *Women's Hospital* (209 beds) dates from 1856, when it was established near the eastern end of Collins-street; in 1858 it was moved to Carlton. *St. Vincent's Hospital*, with 120 beds, was founded in 1893, and in 1910 was recognized as a clinical school attached to the university. The *Austin Hospital for Incurables*, the only one of its kind in Victoria, was opened in 1882 with 52 beds; it can now accommodate 290 patients; all its beds are constantly occupied, and there is usually a waiting-list of 130 to 150 urgent cases.

The *Brisbane Hospital* dates from the earliest days of the settlement. Hospital accommodation was provided in Brisbane in 1825, and in 1828 a general hospital for sick convicts was established. When the penal settlement was broken up, the institution passed into local control under the title of 'The Moreton Bay General Hospital.' On 12 January 1849 was founded the Brisbane Hospital, which for 17 years stood on or near the present site of the supreme court; about 1866 it was moved to its present position in Herston-road. An adjacent hospital for infectious diseases is administered by the committee under contract with the metropolitan authorities. At Sandgate, 12 miles away, there is a convalescent home. The Brisbane hospital can now (1924) accommodate 360 patients, and has 9 medical officers in attendance.

The *Perth Hospital* was established as a colonial hospital on 14 December 1840 in St. George's-terrace, opposite the entrance to government house; in 1855 a new building, now used as an out-patients' department, was erected in Murray-street on a reserve of 7½ acres. In 1860 166 in-patients were treated. The administrative block was built in 1894; in 1897 the surgical wing (with an operating theatre) was erected, in 1904 the medical block, and in 1909 the nurses' quarters. In 1907 the government handed over to the control of the board the *Victoria Hospital* at Subiaco, about 3½ miles away; this has a quarantine reserve of 40 acres, and all infectious cases are treated there. The hospital also contains a mental ward, where patients suspected of mental disorders can be kept under observation before being committed to an asylum. In 1921 4201 cases were treated at the hospital. In 1925 the Perth hospital had 420 beds and 9 resident medical officers.

The *Public Hospital* at Hobart (often called the *Hobart General Hospital*) was originally an institution for the care of sick convicts. For some years houses ill-suited to the purpose were used; in December 1819 work was begun on a 'Colonial Hospital,' which was built on the site of the present general hospital in Liverpool-street. In 1835 the military and civil medical establishments were combined on a military basis. In view of the proposed transfer of Im-

perial establishments in the colony to the colonial government after the cessation of transportation, a joint committee of both houses of parliament was appointed on 23 September 1858; as a result of its findings the colonial secretary gave notice to the comptroller-general of convicts that the hospital would be taken over by the director of public works on 31 December 1859. A board of management was thereupon appointed by the governor-in-council to control the hospital; the board was dissolved in 1874 and a board of visitors substituted. A trained nursing staff was introduced from Sydney in 1875. As the result of a royal commission's report, issued in January 1877, an act was passed vesting the management of the hospital in a board with full statutory powers. In 1884 an isolation hospital was added; the first block of the present nurses' home was completed in 1893;an operating theatre was built in 1895; and a children's hospital attached to the general hospital was added in 1909. Two royal commissions appointed in 1914 and 1915 reported adversely on the state of the hospital buildings, and various improvements have been made since the close of 1917. During the latter year the honorary medical staff resigned owing to the premier's refusal to alter the practice of admitting patients without regard to social position. In 1918 was passed a hospitals act which *inter alia* constituted the hospital board a corporate body. In 1923-4 the hospital accommodation was 225 beds, with five medical officers in attendance.

The *Adelaide Hospital*, situated on North Terrace, is controlled under the hospital act of 1921 by a board of three members with the inspector-general of hospitals for the time being as chairman. Apart from, but worked in conjunction with, the general hospital is a block for the treatment of infectious diseases, to which cases are sent by direction of (and partly at the expense of) local boards of health. The hospital board also controls a consumptives' home on North Terrace, at which provision is made for cancer patients, and a dental hospital in Frome-road, which was opened to the general public in July 1923. The South Australian government laboratory of bacteriology and pathology is situated in the hospital premises.

Hotham, Sir Charles (1806-1855), born at Dennington in Suffolk on 14 January 1806, entered the navy on 6 November 1818 (lieutenant, 1825; commander, 1828; captain, 1833), and after service in many seas distinguished himself during some naval operations against Argentina in 1845. In 1852-3 he was entrusted by the foreign office with negotiations for commercial treaties with Paraguay and the Argentine, and his success was rewarded with the governorship of Victoria. Joseph Latrobe (q.v.), wearied with 15 years of rule in that restless settlement, and confronted on the one side with a constitution that fettered his hands and on the other with a mass of unruly gold-digging immigrants, in 1853 resigned the lieutenant-governorship; the British authorities replaced him with Hotham, who, having no wish for the appointment, insisted that he should be allowed to resign as soon as he obtained flag rank. He reached Melbourne on 22 June 1854 amid general rejoicings, in view of the new and more liberal constitution which he was expected to inaugurate in practice if not officially, and his first declarations of policy were such as his hearers desired. But once in the saddle he found it impossible to depend on popular methods of administration The colony's finances were in great disorder, and he had been directed before leaving England to insist on retrenchment and a sound policy for the future; he therefore almost from the first incurred the unpopularity inevitable by retrenching administrators, and his 'quarter-deck' manners merely augmented the ill-feeling against him. By October he found himself at loggerheads with a large body of diggers, of whom those on the Ballarat field were the most restive, and there followed a startling series of events which are narrated in detail elsewhere (see Eureka Stockade). Hotham was unused to the undisciplined life of goldfields, and not fully informed of the real grievances behind the revolt; but he kept his head, appointed a commission of prominent colonists to enquire into the whole affair, and intimated that he would accept such reforms as the commission should recommend. The actual leaders of the revolt, however, he regarded as rebels against the British crown, and insisted on their trial. Public feeling was so strong that no jury could be found to convict them, and the governor became more unpopular than ever.

Meanwhile the new constitution was on its way. On 2 May 1855 Victoria was given a 'governor-in-chief' of its own, and on 23 October of the same year Hotham received the text of the Imperial act, which he proclaimed on 23 November. Confronted with the transformation of an executive council which he controlled into one which was responsible not to himself but to the legislature, he laid down conditions which, although nowadays they seem harmless because a governor's authority is admittedly nominal, were in the eyes of men accustomed to governors possessing real authority fraught with serious danger. He demanded that his ministers should obtain his personal sanction before introducing any bill into parliament, and claimed a veto on all appointments to public office, announcing at the same time that he would 'not be a party to the appointment of a person whose sole recommendation may be the advocacy of certain political principles.' When these demands were made public there was a storm of indignation, and Hotham withdrew them with the statement that they were merely an outline of his private views. The long struggle to do his duty amid misunderstandings and misrepresentations that were as continuous as unjust had broken down his health; he sent in his resignation on 23 November 1855, but died on 31 December, long before it could reach England. To himself he probably seemed a failure; but he left his successors an orderly colony with sound finances and a much improved system of land administration. (K.C.B., 1846.)

Houtman, Frederik. See Australia, Discovery of.

Hovea, a genus of the family Leguminosae, consisting of shrubs with purple or blue flowers, endemic in Australia. The stamens are united in a sheath opening on the upper side; rarely the upper stamen is free. *H. longifolia*, a tall, ornamental shrub with a wide range, has showy clusters of flowers, occasionally elongating into short spikes. *H. longipes* has a dark-yellow wood, hard and close-grained. Its young pods are eaten by the Queensland aborigines. *H. acuta*, a large shrub, has a firm, close-grained yellow timber.

Hovell, William Hilton (1786-1875), born at Yarmouth in England on 26 April 1785, began to earn his living at sea in 1796 and 12

years later was master of a vessel trading with South America. In 1812 he decided to migrate to New South Wales, where his father-in-law Thomas Arndell had been an assistant surgeon from 1788 to 1796 and had, after the arrival of Bligh as governor, fallen on evil days. Hovell took with him £500 worth of merchandise and a recommendation from the colonial office vouching for him as a desirable settler; after several delays he reached Sydney in October 1813, and in 1814 joined Simeon Lord (q.v.) in his endeavour to establish the New Zealand Trading Company. For some years he was restless. He commanded Lord's trading-vessel the *Trial* (after which Trial Bay is named) on voyages along the coast and to New Zealand—where he came into collision with the Maoris at Kennedy's Bay—and the *Brothers* (another of Lord's vessels) on a voyage to Port Dalrymple which ended in her total loss off the Kent group. In a later venture off the South Australian coast he met on Kangaroo Island sealers who told him of a great lagoon, possibly the estuary of a big river, lying in the bight of Encounter Bay. In 1819 he left the sea and settled near Narellan in New South Wales on a grant of 700 acres which had been given him in 1816; but he could not endure the monotony of straightforward farming, and at once began to explore the neighbourhood as far afield as the Illawarra and Bateman's Bay. In 1823 he opened up the Burragorang Valley, and for this service was granted an additional 500 acres. It was probably this achievement that led Brisbane to couple him with Hamilton Hume (q.v.) in the journey of 1824 to Port Phillip which is described under EXPLORATION BY LAND, for which each of the explorers received another 1200 acres. On their return from Port Phillip press paragraphs soon made it evident that Hume was jealous of Hovell's participation in the exploit, and the *Australian* protested that 'Mr. Hovell lacks all the qualities befitting a bushranger.' The *Sydney Gazette*, however, lauded him as 'the Mungo Park or Belzoni of Australia.'

As a result of the mistake by which the terminal point of the 1824 journey had been identified with Western Port, Hovell was in 1826 attached to the party which Darling sent to establish a settlement at that place. This party was in charge of Captain Samuel Wright of the Buffs regiment, assisted by Captain F. A. Wetherall of H.M.S. *Fly*; Hovell was sent with them to continue his explorations. He investigated carefully the country lying between Cape Paterson and Kooweerup Swamp, and the area north-west of that swamp to Carrum Swamp (which he provisionally named after himself) and the cliffs near St. Kilda; from the last-named point he corrected the mistake of 1824, roughly identifying the district in which Hume and he had really terminated their journey. His report, though optimistic, was not sufficiently favourable to justify the continuance of the Western Port settlement, and early in 1828 it was abandoned. Hovell's reward for this service was 1280 acres, but on terms which he described as little better than an absolute purchase; and as the previous grant of 1200 acres had to be sold to defray the expenses of the 1824 expedition (and returned a surplus of £20 only), he found himself in 1829 with little more than his original Narellan grant of 700 acres to farm on. Until 1837 he applied repeatedly for a further grant, but Darling's opposition stood in his way; the colonial office, however, in 1833 suggested that remunerative employment might be given him, and Bourke in 1837 remitted a debt of long standing owed by him to the government.

In 1853 Hovell revisited Port Phillip, and was welcomed as the original discoverer of the district. This stirred up Hamilton Hume, whom Darling had always recognized as leader of the 1824 expedition, to reassert his claims and to declare that Hovell, not he, had made the mistake about Western Port. The details of this unhappy controversy are carefully analysed by Ernest Scott in the *Journal* of the Royal Australian Historical Society (vii, 289-307), and Hovell's journal of the journey is reprinted in the same volume. During his visit to Geelong Hovell identified the terminal point of the journey as Bird Rock on Corio Bay, almost opposite Point Henry. There was a recrudescence of the dispute in 1874, after Hume's death. Hovell died at Sydney on 9 November 1875. His widow bequeathed to the university of Sydney some property at Goulburn for the endowment of a lectureship in geology and physical geography. His journal, on which Bland's account of the famous journey was founded, is in the Mitchell Library at Sydney.

The publication of this journal and of accounts founded on it requires separate notice. On 10 February 1825, less than three weeks after the return of the explorers, the *Australian* and the *Sydney Gazette* published almost identical summaries of the journal (the *Gazette* omitted a few sentences). A copy of the *Australian* was sent by Hovell to Jules Lejeune, the artist of Duperrey's expedition (see EXPLORATION, FRENCH), and by him communicated in a French translation to the *Nouvelles Annales des Voyages* (vol. 28, pp. 417-21). In December 1825 Bland announced the forthcoming publication of a book founded on the journals of both explorers, but shortly afterwards fell ill; when towards the end of 1826 he had a good deal of the matter in print, the supply of paper suddenly gave out, and publication was deferred till 1831. In that year appeared the first edition of the *Journey of Discovery to Port Phillip*, which Bland wrote up almost entirely from Hovell's journal, Hume's being scanty and imperfect. A second edition was published in 1837.

Hovell was by no means the ignorant old 'sea-dog' of the usual stories, most of which emanated from Hume's friends and were intended to depict him as a cowardly Englishman without any bush-craft, a mere foil to the gallant and expert young bushman of Australian birth. This malicious picture of him is sufficiently contradicted by the fact that he formed close friendships with several of the scientific staff of the Duperrey expedition, who were members of the Institut de France.

Howard, CHARLES BERNARD (1810-1843), born in England in 1810 and educated for ministerial work in the Church of England, was in 1834 appointed 'colonial chaplain' of the then still inchoate colony of South Australia. Sailing in the *Buffalo* with Governor Hindmarsh, he reached the colony on 28 December 1836, and as soon as the site of Adelaide was determined established a temporary church in the new town under a large sail which he dragged from the shore seven miles on a small truck. His next church was a room in the Adelaide court-house, itself a temporary building; then the Society for the Propagation of the Gospel sent him out a wooden building, but he thought it too flimsy, and pledged his credit for £1000 wherewith to erect

a stone church on North Terrace, which is now Trinity church. His tolerant broadmindedness endeared him to colonists of all denominations, and John Wrathall Bull declares that 'his example did very much to produce the harmony which prevailed in the colony in his day . . . . especially exhibited in the pleasing actions of Christians of all denominations contributing to the building funds for the erection of places of worship under whatever name they might be called.' For his own denomination he procured the building of churches in East Adelaide, Port Adelaide, and the Sturt: but in 1843, when the colony was almost bankrupt and Howard himself in very poor health, he was served with a writ for the amount borrowed to build Trinity church, and the shock killed him. He died on 21 July 1843. In 1840 he published in Adelaide a *South Australian Church Hymn Book.*

Howe, GEORGE (1769-1821), born on St. Kitts in the West Indies in 1769—his father brought the first press to the island, and was for a time official printer there—in the early nineties went to England and obtained employment in London printing-houses, among them the office of *The Times.* The experience he gained there stood him in good stead when in 1800 he was transported to New South Wales—for what crime we do not know, but he had adopted the *alias* of 'George Happy'—and is reflected in the detailed orders he sent to England afterwards, e.g. for type which 'must be had from the founderies of either the late Messrs. Caslon or Mr. Figgins.'

Reaching Sydney in November 1800, Howe was according to his own account immediately employed as government printer. The official budget of the colony, however, shows that during 1801 there was no government printer; but early in 1802 Howe was given the post, and impressed King as 'ingenious.' Late in the year he issued the first book known to have been printed in Australia—the *New South Wales General Standing Orders*; and early in 1803 he obtained permission from King to collect materials for a weekly newspaper, the first issue of which was made on 5 March 1803 (see PRESS). This *Sydney Gazette and New South Wales Advertiser* was nominally Howe's private speculation, but he was allowed to use the government type and press. For some years he did all the work—bought the paper, set up the matter (which he 'invented and obtained without any auxiliary assistance'), worked the press, and delivered copies to subscribers. His matter was severely censored by the governor's secretary, and his office was a small ramshackle building attached to government house, with a loft for stores; when Johnston's soldiers were looking for Bligh, Lieutenant Laycock of the Corps 'nearly dislocated the principal joints in his body' while searching the loft. Up to June 1806 Howe was a convict maintained at government expense, but on the 4th of that month received a full pardon, which incidentally threw him on his own resources for a livelihood, and accounts for his description of his first seven years of press-work as 'goading penury.' He eked out an existence by various devices; at one time he issued a *New South Wales Pocket Almanack*, price five shillings sterling, at another he opened an evening school to teach several branches of mathematics, 'Writing (if necessary), and the Grammar of the English Tongue.' He had rivals, one of whom offered to teach 'the English language, agreeable to the modern pronunciation, and grammatically, if required.'

With Macquarie better times came. That governor, astonished to find that Howe received no allowance as government printer, procured for him a salary of £60 a year. In 1812 he married a rich widow, and combined journalism with store-keeping; he began to make money, in 1813 went shares with Mary Reiby (see REIBY, THOMAS) in a speculation in sandalwood, and in 1817 was one of the original subscribers to the Bank of New South Wales. He was never quite freed from governmental supervision, for in June 1817 he had to obtain Macquarie's permission before printing handbills for the officers of the 46th regiment—and did not get it. He died in Sydney on 11 May 1821.

Howe, MICHAEL (1787-1818), born at Pontefract in Yorkshire in 1787 and apprenticed in youth aboard a merchant-vessel sailing out of Hull, after two years' service ran away to join a man-of-war, and a little later deserted and took to highway robbery. In 1811 he was caught, convicted, and sentenced to transportation to Australia for seven years, and reached Hobart in the convict transport *Indefatigable* on 19 October 1812. He was assigned to John Ingle, a former superintendent of convicts whose character (according to Macquarie and Davey) was none too good, but who was in spite of that a prominent settler. Growing restive, Howe soon escaped to the bush and joined a gang of bushrangers which had been formed as far back as 1810 by John Whitehead, and at one time had as many as 28 members. In May 1814 Macquarie, pursuing his policy of giving every criminal a chance of amendment, offered all Tasmanian bushrangers an amnesty if they surrendered on or before 1 December: Howe is said to have come in with the rest, but was out again and in full career by August, taking the opportunity to raid a farm of Ingle's only 12 miles out of Hobart. The fate of Whitehead is uncertain. The story told in Bent's pamphlet (see below) is that he and Howe had agreed that, if either was killed in a fight with the police, the survivor should cut off the dead man's head to prevent the pursuers from getting the reward; that Whitehead was killed in such a fight about mid-May of 1815, and Howe did what he had promised; but that the head was afterwards found, and the body was gibbeted on Hunter's Island. In September 1815, however, William Stewart, master of the merchant-sloop *Fly*, reported to the colonial secretary at Sydney that several bushrangers—John Whitehead among them—had been taken off by a whaleboat to one of the islands in Bass Strait, and were raiding the seal fisheries there. As another Whitehead, James, had joined the gang early in 1815 confusion is inevitable.

By the end of 1815, at any rate, Howe was the acknowledged leader of the gang. Remembering his early training, he at once imposed on his companions an almost naval discipline: it is said, indeed, that he administered to all who joined him an oath of obedience taken on the Anglican prayer-book—but this is probably a misinterpretation of the scene witnessed by one of his captives, when, before sending to the governor a letter signed by 11 of the bushrangers, Howe swore them on a prayer-book to abide by its terms. In 1816 he was signing himself 'Lieutenant-governor of the Woods' and in 1817 'Governor of the Ranges,' and he corresponded with both Davey and Sorell as an equal. Towards the end of Davey's term began a steady process of hunting down the gangs, and an aboriginal girl who had been Howe's com-

panion ever since 1814, offended at some brutality of his, offered herself to the police as a guide to his haunts. Consequently on 28 April 1817 Howe sent to Sorell, Davey's successor, a letter offering to surrender; Sorell granted him a conditional pardon for all crimes except murder, and promised to obtain if possible the King's mercy even for murders, provided that Howe made a full confession and betrayed his companions. The confession was eagerly expected, because it was widely believed among the settlers that the bushrangers had friends in high places. Howe was examined frequently by magistrates, and his depositions are described as 'voluminous and tedious,' but nothing came of them. The only man definitely implicated by Howe—as far as is now known—was the chaplain Robert Knopwood (q.v.), and his innocence was afterwards proved incontestably. No other information of any value resulted, and, when in September Howe disappeared again, Macquarie revoked the pardon with the comment that 'if ever taken alive, he will be a very fit and proper object to make a Public and awful example of.' As soon as the escape was known, Sorell at once sent off Mary, the aboriginal girl, to Sydney lest Howe should revenge himself on her. In April 1818 a government launch was stolen by a gang of prisoners in order to pick up Howe and put him aboard an American vessel, but the plot miscarried. Thenceforward he was alone and in constant danger; he robbed a few stockmen's huts, but was once more thwarted; in September 1818 a party including the New South Wales blackfellow Musquito (q.v.) took from him his pistols (a sore loss) and a knapsack in which was found his 'Journal of Dreams,' a little book made of kangaroo skin with the writing in kangaroos' blood. Besides a record of his dreams, which were for the most part of capture or death, the book contained long lists of vegetable and flower seeds and fruit-trees; for his waking dreams were often of settling down somewhere —probably in another colony under another name —on a farm of his own. But his pursuers were hot on his trail. On 21 October they laid a trap for him, concealing a soldier named William Pugh and a convict servant in a hut which he was expected to visit: there was a desperate struggle, and Howe was at last killed with the butts of his opponents' guns.

In March 1819 a small octavo pamphlet—the first book published in Tasmania—was issued by Andrew Bent (q.v.) under the too optimistic title *Michael Howe, the Last and Worst of the Bushrangers of Van Diemen's Land.* The first edition, priced at five shillings, was sold out by June, and in July another was issued at half a crown. To-day but a single copy remains, and that is in the British Museum; but the original manuscript, or the copy of it made for submission to Sorell's censorship, was re-discovered in Tasmania in 1925. This pamphlet is the sole authority for the greater part of Howe's career, but the *Historical Records of Australia* (III. ii) contain many references to him which are not always consonant with Bent's story; in such cases this article follows the *Records.*

Howe, Robert (1795-1829), son of George Howe (q.v.) was born in London on 30 June 1795, and in 1802 was brought by his mother to join his father in New South Wales. From the first issue of the *Gazette* in 1803 he was brought into his father's business, and in 1821 succeeded him as government printer, Macquarie considering him 'sufficiently competent.' His ownership of the *Gazette* was more prosperous and more exciting than his father's: in 1822 he was stabbed dangerously by a drunkard who had brooded over a friend's supposed grievances, and in 1824 a new newspaper came into competition with him. The attempt to murder him is interesting because at the trial of the assailant it was argued that stabbing was not a legal crime within the colony; the point was referred to London, and was of course dismissed, but 'in consideration of the doubt existing in the Colony as to the nature of the Crime' the sentence was reduced from hanging to transportation. In 1823 Robert's printing difficulties were nearly as great as those of his father; several issues of the *Gazette* were printed on China paper, and the ink (which had to be manufactured in the office) faded and made the matter almost illegible. In 1825 China paper was used again, two sheets being pasted together to provide a sufficient thickness.

On 14 October 1824 appeared the first issue of the *Gazette's* first competitor—the *Australian,* edited by Dr. Wardell, an English barrister, and for some time financed by W. C. Wentworth; one of Howe's employees was induced to take over the printing of it. The immediate results were favourable to Howe. As Wardell was not subject to censorship, Howe claimed his freedom also, and Brisbane granted it, reporting to Bathurst later that the concession was of benefit to the public; but Howe further claimed that, as he no longer had a monopoly of the press, he could not insert government proclamations and advertisements for nothing—and Brisbane had to pay. Darling soon found the expense too great, and compromised by giving Howe £150 a year for inserting all government proclamations and orders in the *Gazette* free of charge and supplying 25 copies of each issue for official use. Wardell's competition might have been serious, had not his airs of superiority alienated a number of business men and his attacks on Darling brought Howe definite and persistent official support. From May to September 1825 Howe experimented with a *Weekly Commercial Express,* mainly devoted to advertisements and commercial notices, but his plant and staff were inadequate to the publication of two journals. In 1826 another competitor, Edward Smith Hall (q.v.), brought out the *Monitor* (first issue, 19 May); his competition seems to have been more severe, for within two months Howe was persuading Darling to deprive Hall of the services of two convict printers—Darling, whose opinion of Hall was the lowest, needed little persuasion. On 1 January 1827 the *Gazette* appeared as a daily paper. The removal of the censorship, though justified and beneficial, allowed journalism to become more personal and often virulently aggressive, and Howe in 1826-7 found himself involved in several libel actions; in April 1826 John Macarthur threatened to 'destroy' him, in January 1828 he was horsewhipped by William Redfern, and later in that year his attacks on Chief Justice Forbes earned a severe reprimand from the colonial office. Before, however, this reprimand could reach him, he was drowned off Fort Denison in Port Jackson on 29 January 1829.

The reprimand was not the only thing he missed. For several years (since October 1825) he had been petitioning governors and the colonial office for the title of 'King's printer.' Brisbane suggested delay, but promised support when he reached England; Darling transmitted a fresh petition in 1828, but would not recom-

mend it; however, the colonial office on 11 November 1828 decided to grant Howe the title—too late to do him any good, as he was dead at least five months before the news reached Sydney.—A younger brother, GEORGE TERRY HOWE, was in 1825 made by Arthur government printer of Tasmania, in partnership with James Ross. He was also editor of the *Tasmanian Gazette*, which was issued first at Launceston on 5 January 1825 and then after a long interval—Howe having meanwhile dissolved partnership with Ross—at Hobart on 3 March 1827. On 30 August, however, he sold the paper to J. C. Macdougal.

Howitt, ALFRED WILLIAM (1830-1908), was the best-known of a family of Quakers which has left its mark on Australia. His grandfather, Thomas Howitt, was a Derbyshire farmer, whose three younger sons all visited (and two of them settled in) Victoria. GODFREY HOWITT (1800-1873), the youngest, an M.D. of Edinburgh and an ardent botanist, migrated to Australia in 1839, taking with him his brother RICHARD HOWITT (1799-1869), a nephew, and two brothers-in-law—one of whom, Robert Bakewell, helped to found the well-known firm of Goldsbrough, Mort & Co. Richard bought a farm which is now the Melbourne suburb of Alphington, spent a good deal of his time in excursions into the Mornington bush, and in 1844 returned to England, where he published *Impressions of Australia Felix* (1845), much praised at the time for its vivid pictures of bush life. Godfrey settled down in Melbourne to practise his profession, established a fine garden at the corner of Collins and Spring streets, was one of the first three honorary physicians attached to the Melbourne hospital (1847), an original member of the council of the university (1853), and a founder of the Royal Society of Victoria (1854). His reputation as a botanist and entomologist extended beyond Australia, and when he died in 1873 he bequeathed to the university his entomological collections and £1000 for a scholarship in natural science. It was to Godfrey that WILLIAM HOWITT (1792-1879), father of A. W. Howitt, came out in 1852, bringing his two boys with him and leaving his wife—the celebrated Mary Howitt—and her daughters at Highgate during his absence. Twenty years of almost incessant authorship and journalism had driven him, when the news of the Australian gold-discoveries reached England, to seek relief in a new country and a more vigorous outdoor occupation. The party reached Melbourne on 13 September 1852, and a month later set out for the diggings near Beechworth; unsuccessful there, they turned prospectors and discovered the Nine-mile Creek (Yackandandah) field, which was immediately overrun with diggers; after a visit to Albury, they returned to Melbourne, tried their luck at Bendigo, revisited the Beechworth field, and made their way back to Melbourne via Bendigo, Ballarat, and Geelong. William Howitt had by this time forgotten his distaste for literature; after short visits to Sydney and Tasmania, he returned with his younger son, CHARLTON HOWITT (1838-1863), to England, published two important books on Australia—*Land, Labour, and Gold* (1855) and a *History of Discovery in Australia, Tasmania and New Zealand* (1865)—besides several minor books inspired by his visit, renewed his voluminous literary output, became a spiritualist, settled in 1870 at Rome (where he helped to introduce eucalypts for planting on the marshy Campagna), and died there on 3 March 1879. Charlton Howitt, who left Australia reluctantly, sailed again in 1860 for New Zealand, went prospecting in the Canterbury district, and was drowned in Lake Brunner in 1863 while opening up a track across the Southern Alps.

ALFRED WILLIAM HOWITT, the chief subject of this article, was born at Nottingham on 17 April 1830, educated at Heidelberg in Germany and University College, London, and brought by his father to Australia in 1852. After the goldfields adventures narrated above he settled down temporarily on his uncle's farm at Caulfield, but soon became a drover and made a reputation as a fearless and expert bushman. In 1859 he was employed to report on supposedly pastoral country in the Lake Eyre district, which he found drought-stricken; in 1860 he was exploring and prospecting in Gippsland; and on 18 June 1861 he was made leader of one of the expeditions sent out about that time in search of Burke and Wills (q.v.). Howitt's party met Brahe (a former member of the missing expedition) on the Loddon and, guided by him, made straight for the camp at Cooper's Creek where the explorers had last been heard of; there they found the only survivor, John King, and the bodies of the two dead leaders. These Howitt at first buried where they lay, but afterwards, making a second journey to the Creek, brought back for a public burial in Melbourne. (Further details of all these journeys of 1859-62 will be found under EXPLORATION BY LAND).

For these services Howitt was in 1863 appointed police magistrate and goldfields warden in Gippsland, holding the positions until 1889. During the second expedition of 1862 to Cooper's Creek he had begun to study carefully the aboriginal tribes he encountered, making friends especially with the Dieri of the Creek. When settled in Gippsland he continued his studies, and anticipated the later methods of Spencer and Gillen by being initiated into the local Kurnai tribe and partaking in their secret ceremonies. Towards the end of the sixties he met Lorimer Fison (q.v.) and in 1871 began to collaborate with him in his ethnological studies, the result of the partnership being the publication in 1880 of *Kamilaroi and Kurnai*, which was followed up by a number of papers on aboriginal matters either published in pamphlet form or contributed to the *Journal* of the Royal Anthropological Institute or the *Transactions* of the Royal Society of Victoria. In 1889 he left Gippsland on appointment as secretary of mines to the Victorian government; in 1896 he became a commissioner of audit; and in 1901 retired from the public service to devote himself entirely to scientific studies. Ethnology was his chief preoccupation, and *The Native Tribes of South-east Australia* (1904) his most important book, but a paper on the eucalypts of Gippsland published in 1889, and reports on the geology of Gippsland contributed to a geological survey of Victoria in 1874-7, show his active interest in other branches of science. During a visit to England in 1904 he received an honorary doctorate of science from the university of Cambridge. He was also a fellow of the Geological Society and the Royal Anthropological Institute of Great Britain, and of the Linnean Society of New South Wales, and a medallist of several Australian learned institutions. He died at Metung in Gippsland on 7 March 1908, bequeathing his minerals to the university of Melbourne, his library to Queen's

College within that university, and his botanical collections to the national herbarium. With Fison he is described by Sir Everard im Thurn as 'pioneers of the new anthropology, who by their researches into the organization of the human family have given the study the character of an exact science.' (C.M.G., 1906.)

Hughes, Sir Walter Watson (1803-1887), born at Pittenweem in Fife on 22 August 1803, was educated at Crail, apprenticed to a cooper, and then took to the sea. In 1829 he found himself in Calcutta, and there purchased a vessel, *The Hero,* in which he traded between Calcutta and China for eight years. In 1842 he sailed her to Adelaide and settled there. After suffering many reverses, he acquired great wealth from the development (in 1860) of copper-mines at Wallaroo and Moonta on Yorke Peninsula; he had discovered the existence of copper there many years earlier, but had been too busy to exploit his discovery. In December 1872 he desired to give £20,000 to a college which had been founded to train students for the Nonconformist ministry, but Dr. Jefferis (q.v.) persuaded him to allot it to the establishment of a university at Adelaide. This munificent gift was followed by a similar one from Sir Thomas Elder, and the university was established in 1874. Soon afterwards Hughes returned to England, lived there quietly for many years, and died at Chertsey on 1 January 1887. (Kt. Bach., 1880.)

Hughes, William Morris, born in Wales on 25 September 1864 and educated at Llandudno grammar school and St. Stephen's school, Westminster (where he was a pupil-teacher and was inspected by Matthew Arnold) in 1884 migrated to Australia, landed at Brisbane, and was employed on work of various kinds—stone-breaking, carpentry, etc.—on the railway then being constructed from Mitchell to Charleville. During the next few years he did what jobs came to hand—boundary-riding, sinking post-holes, shed-building, work aboard coasting vessels (in one of which he saw the Gulf of Carpentaria), travelling stock from Peak Downs in Queensland to New South Wales. Then, tiring of out-back life, he came to Sydney, worked as a 'super' in Rignold's Shakespearian productions, and opened a small shop in Balmain in which he sold books and repaired locks and umbrellas. During the maritime troubles of 1890 he kept aloof from the strike, but, when the defeated strikers had dissolved into an unorganized rabble, created a union for them and was for many years its secretary.

In 1894 this union, which was all-powerful in the Lang division of Sydney, returned him as its representative to the legislative assembly. He entered Parliament at a critical moment in the history of Labour, during the discussions on the pledge of 'solidarity' which drove from the party several of its most prominent members (see Labour Parties), so that Hughes found himself in a position favourable to the recognition of his exceptional brilliance. At the same time he was active in building up the organizations of other trades, especially the shop assistants and trolly- and dray-men, and the passing of the early closing act of 1900 was due mainly to his untiring advocacy. Outside his colony he had for the time few interests. Like his fellow Labour members, he was willing to support a federation with a single legislative chamber, an elective ministry, and the initiative and referendum, but was indifferent to any less democratic form; the rejection of the referendum as a piece of political mechanism by the convention of 1897-8 made him and the rest opponents of the bill, but the party's platform for the 1898 elections did not even mention federation, although the bill was in reality the main issue of the campaign.

When federation was accomplished, Hughes, returned by an enlargement of his old waterside constituency, was one of the six New South Wales representatives of Labour in the Commonwealth parliament, and at once became chief adviser of the party's federal leader, J. C. Watson (q.v.). In Watson's ministry of 1904 he was minister for external affairs: he had, like other ambitious Labour leaders, studied for the bar and had been admitted in 1903, but wisely refrained from claiming the attorney-generalship until he had gained more experience. When Watson left politics, Hughes had claims to succeed him; but his brilliancy was against him, and Andrew Fisher took the vacant place, Hughes remaining chief adviser, and being responsible for most of the decisions of the federal party during its support of Deakin. He was chairman of the royal commission on the iron bonus in 1904, and of the navigation commission (whose labours resulted in the Commonwealth navigation act) of 1904-5, and in 1907 went to London to explain the provisions of the measure at a conference with shipowners and representatives of the British government. In 1908-9 he was attorney-general in the first Fisher ministry; and when in 1910 the Labour party came back to the federal parliament with a strong working majority, he was given the attorney-generalship in the second Fisher ministry, also taking special charge of the measures, military and naval, designed to organize and strengthen Australian defence, in which he had taken particular interest since his first entry into federal politics. While temporarily out of office in 1913-4 he was offered by his opponents the chairmanship of the newly established inter-State commission, but preferred to continue a political career. In September 1914 he returned to office as attorney-general in the third Fisher ministry, and became prime minister when Fisher in October 1915 took the high-commissionership. Throughout the war and until February 1923 he was prime minister, first of a purely Labour ministry (October 1915 to November 1916), then of a truncated Labour ministry—the anti-conscriptionist members of the first having resigned—(November 1916 to February 1917), then of a 'national war ministry' in which six members represented the 'liberal' party (February 1917 to January 1918), finally of a much enlarged and often reconstructed 'national' ministry, which in five years had four different treasurers, four ministers for customs, and nine honorary ministers (January 1918 to February 1923). Through all these changes Hughes remained the real as well as the nominal head, maintaining and expanding his prestige by two visits to England (in 1916 and 1918-9) during which he took a prominent part in meetings of the imperial cabinet and in the negotiations and conference that produced the treaty of Versailles. In February 1923 he resigned the prime-ministership, retaining his seat in parliament (in 1907 he had left West Sydney for Bendigo, and in 1923 left Bendigo for North Sydney), and has since taken a comparatively small part in Australian politics. In 1924 he undertook a comprehensive lecturing tour throughout the United States. (P.C., 1916.)

Hugo, JONATHAN BURKE, son of a Dublin tobacconist, arrived at Launceston in Tasmania about the end of 1811 in the 100-ton brig *Active,* which he had obtained with its cargo on credit from Alexander & Co. of Calcutta. At this time he called himself McHugo. While he was at Launceston, Major Gordon (the commandant at Port Dalrymple) was, to quote Macquarie's official despatch, 'So far Imposed on by the wild and extravagant Nonsense of Mr McHugo as to Imagine him to be one of the Royal Family Incog. and possessed of Authority at pleasure to supersede All Governors Commanders, etca. etca., wherever he pleased to Visit. In this Belief, Lieut. Col. Gordon had Actually Surrendered his Command to Mr McHugo, who was likely to have made a Very Alarming Use of the Power so Yielded to him, had not the Other Officers found it Necessary, to their personal Safety and the Duty they owed their Sovereign, to remonstrate with Col. Gordon, whereby they at length Effected the Measure of sending Mr McHugo hither under a Military Guard.'

In Sydney Hugo was examined by a medical board which pronounced him to be 'in a state of outrageous insanity;' in April 1812 he was sent back to Calcutta, was confined for 2½ years in a lunatic asylum, and eventually reached London, where in 1817 he was bombarding the colonial office with petitions. He claimed to be descended from Earl Bothwell and Mary Queen of Scots, and to be the rightful heir to the crown of England, but declared he would be content with 'a Moderate Subsistence.' Whether he obtained one, or what happened to him after 24 July 1817, has never been discovered.

T. D.

Hume, ALEXANDER HAMILTON (1797-1873), born at Parramatta on 18 June 1797, was the eldest son of Andrew Hume, who was in 1789 a superintendent of convicts at Woolwich, and for his knowledge of farming was selected with eight others to act as superintendent and agricultural instructor of convicts in New South Wales. He left England in the *Guardian* in September 1789, but owing to her breakdown at the Cape of Good Hope was transferred to the *Lady Juliana* and reached Port Jackson on 3 June 1790. In July Phillip sent him to Norfolk Island, apparently because he had some experience in growing and treating flax, and it was desired to utilize the New Zealand flax which grew in abundance on the island. Ross, then commandant, gave him his choice of convict labourers and settled him at the Cascades. The enterprise, however, was not a success, and towards the end of 1792 Hume was brought back to Sydney and made superintendent of convicts at Toongabbie, with charge of the government live stock there. King dismissed him from this post in 1800, Johnston reinstated him in 1808, and Foveaux again dismissed him in September; in November 1812 Macquarie granted him 100 acres near Appin, and he settled there.

The boy Hamilton was educated by his mother, and spent much of his time in bush adventures. In August 1814 he set off with his brother John to explore the bush southwards, and discovered the Berrima district, to which in 1815 he piloted Oxley's flocks. In 1816 he pushed on to Sutton Forest, and in 1817 accompanied James Meehan (q.v.) on the journey in which the Goulburn Plains and Lake Bathurst were discovered. For these explorations Macquarie gave him a land-order for 300 acres—but it was many years before he acquired the land. Between 1818 and 1822 he was a member of several exploring parties; in 1821 he discovered Yass Plains, and in 1822 with Alexander Berry worked up the Clyde on to the tableland near Braidwood.

When Brisbane in 1824 decided to encourage an expedition across country from Lake George towards Spencer Gulf, Berry recommended Hume as its leader. Brisbane joined with him William Hovell (q.v.); the story of the expedition is told under EXPLORATION BY LAND. For this work Brisbane granted him 1200 acres on the Crookhaven River, which in 1837 he passed on to Berry. In 1828 he accompanied (and was of great use to) Sturt on the journey during which the Darling was discovered; but the adventurous life had impaired his health, and he abandoned exploration to settle at Yass Plains, where Darling granted him 1280 acres. In 1855 Hume entered into a public controversy with Hovell about the expedition, the points at issue being (*a*) who led the expedition, (*b*) whether Hume as well as Hovell mistook Corio Bay for Western Port. With regard to the first point, though the exploration was certainly conducted in partnership, by 1827 the colonial office and Governor Darling recognized Hume as the leader. The second point is settled by Hume's own letter of 24 January 1825, in which he assured Brisbane that they had reached Western Port—a statement which he repeated to Earl Bathurst in April 1826. The controversy, however, let loose a flood of charges against Hovell—made partly by Hume himself, partly by three of his friends who as assigned servants had accompanied the expedition—which have since been accepted as facts without any further enquiry, and included in nearly all recent accounts of the journey. Nothing in the journals of the two explorers, or in any documents of the '20s or '30s, corroborates them; indeed, the mutual hostility of the leaders which they imply (and some explicitly assert) cannot be reconciled with the first-hand evidence of the journals. Against that no amount of railing accusation made 30 years afterwards by a sick man (who, by his own admission, had a very bad memory) can possibly prevail. At the same time the existence, as far back as 1825, of a certain jealousy between the explorers is shown by an anonymous advertisement in the *Australian* of 11 April 1825, which claims the whole credit of the discoveries for Hume and attacks Hovell as totally lacking in bushcraft.

In 1867 Hume published in London a *Life of Edward John Eyre.* He died at Yass on 19 April 1873.

Humus is the dark-coloured organic substance in the soil produced by the decay of vegetable matter. Moisture and a certain degree of warmth are necessary for its production. In sandy desert soils it may be altogether absent, while it forms the chief constituent of soils of the nature of peat. The process of decomposition is due in the main to micro-organisms. The nitrogenous material of the plant undergoes a process of nitrification, and the resulting humus becomes the principal storehouse of the nitrogen required (in the form of nitrates) for the next generation of plants. The cellulose is broken down, and converted into humic and ulmic acids, and finally into carbonic acid—all of which exercise a solvent action on the soil, and render the soil-constituents available for plant-food.

The presence of humus increases fertility in several ways. It has itself a strong affinity for water, which it retains, so that its presence minimizes aridity; it forms a mulch in the surface soil, thus preventing undue evaporation; as a non-conductor of heat, it helps to preserve an equable temperature; and it improves the texture of the soil, lightening stiff soils, binding sandy ones, and in all cases maintaining a friable condition and preventing impaction. Further, the production of vegetable acids and carbonic acid, and the formation of nitric acid referred to above, greatly increase the fertility of the soil, in the one case by dissolving out insoluble mineral soil-constituents, in the other by supplying nitrates, which are among the most valuable of fertilizers. Humus itself also contains a certain proportion of mineral fertilizing constituents, which are readily available as plant-food. It is noteworthy that the humus of soils in semi-arid regions contains a relatively larger proportion of nitrogen than the humus of moister districts; this, combined with the fact that these dry soils are richer in all kinds of plant-food than those in moister regions, accounts for the extraordinary increase of growth in such districts that follows good rains.

The presence of humus is, therefore, an essential condition of soil-fertility. Unfortunately it is the ingredient most subject, under dry conditions, to alteration and destruction. When humus loses its moisture, it is rapidly 'burnt out' by the combined action of sun and air; evaporation proceeds at a rapid rate, and results in the wilting of crops and herbage. The final result is the formation of 'scalded' spots (or even plains), and the subsequent removal of the fine surface soil by the wind. It is not uncommon in semi-arid districts for the soil to be heaped up by the wind against fences, so as to obliterate them completely. The showers of 'red rain,' occasionally reported, occur when rain falls through atmosphere loaded with this fine dust. The presence of alkali in the soil, or in the water used for irrigation, is also rapidly destructive of humus. Soils derived from limestone, or rich in lime—such as those derived from basalt and other basic rocks—are usually richer in humus than others, the lime combining with the humic and other vegetable acids to form more or less insoluble compounds.

Owing to the great importance of humus as a soil-ingredient, and the fact that it is the one most easily destroyed, the problem of maintaining the supply is among the most important with which the farmer is faced. Stubble and crop residues should be ploughed under in preference to being burnt off; this will do something to prevent the too rapid loss of vegetable matter. But it will generally be necessary to increase the supply of humus by other means. Among those most generally adopted are (1) the application of farmyard manure, or of compost manure, and (2) the ploughing under of a green crop. Except in cases where animals are stalled and bedded, farmyard manure consists wholly of animal excrement and contains very little vegetable matter; though excellent as manure, it is incapable of supplying the necessary humus. The compost-heap, or pit, is a very valuable adjunct to the farm, and should be found more frequently. The value of compost-heaps arises from the fermentation of vegetable and animal refuse in the presence of lime and soil, by which bush-scrapings, dead leaves, weeds, tops and stalks of vegetables, bones and animal refuse can be converted into a manurial substance rich in decaying organic matter and a cheap source of humus. Such a heap is made of alternate layers of refuse and of lime covered with earth. When more refuse has been collected, add another layer of it and then a layer of lime, covering the whole again with earth till the heap is three or four feet high. To keep the heap moist, all waste water from the farm and house (such as slops, urine, etc.) are added through a hole which is kept open at the top. In a few months it is ready for use. Pits may be made in the same way. While one heap or pit is fermenting, a second should be prepared.

Green-manuring—the ploughing under of a quickly-growing green 'catch-crop,' preferably a leguminous one—is the method of humus-supply most generally practised, and is specially suited for orchards, where a green crop can be grown between the rows and ploughed under without disturbing the trees. In other cases the catch-crop is grown when the land is lying idle between the harvesting of one main crop and the sowing of another. The nature of the catch-crop will depend upon the district, the time of year, etc.; but it should be one that produces abundant foliage. Leguminous crops are the most profitable; the foliage forms humus, and the roots are active agents in the formation of nitrates from the air within the soil, thus increasing the plant's supply of nitrogen. As an indication of the fertilizing value of green-manuring, it may be pointed out that, under favourable conditions, vetches yield about 10 tons of tops and three tons of roots per acre. The tops contain about 0.5 per cent nitrogen, the roots 0.2 per cent. By ploughing under such a crop the soil will gain about 1½ tons of dry vegetable matter (humus), and about 120 lb. of nitrogen—equivalent to six cwt. per acre of sulphate of ammonia, or nearly half a ton of dried blood.

F.B.G.

Hunter, JOHN (1737-1821), born at Leith in Scotland on 29 August 1737, was sent to the university of Aberdeen about 1753 to study theology with a view of entering the Presbyterian ministry. But the boy longed for a sea life, having already accompanied his father, a shipmaster, on a voyage to Norway which ended in shipwreck; and in 1754 he left the university suddenly and secured a position as captain's servant aboard H.M. sloop *Grampus*. This was the usual mode of entry into the navy for young men wishing to become officers; Lord Nelson himself began his career as captain's servant aboard H.M.S. *Triumph*. After 12 months as captain's servant young Hunter for 15 months learnt practical seamanship as an A.B., and was then rated midshipman in H.M.S. *Neptune* (master's mate, 1764; master, 1768; lieutenant, 1780; commander, 1782; captain, 1786; rear-admiral, 1807; vice-admiral, 1810). In the *Neptune* he took part in the expedition against Rochefort (1757) and the capture of Quebec (1759). At the end of the Seven Years' war he was appointed to the *Tweed* frigate, serving on the Newfoundland station, and for the next 13 years devoted himself to the close study of navigation, astronomy, and maritime surveying. In 1776 Lord Howe selected him to be master of his flagship the *Eagle*, and for his good work in the war of the American revolution insisted on having him promoted lieutenant, the examination for which rank he had passed in 1760. As lieutenant Hunter served in the *Berwick* at the Doggerbank action of 5 August 1781, but re-

joined Howe in the West Indies in 1782 as admiral's third lieutenant; almost immediately he was promoted to be first lieutenant of the *Victory*, and was then given command of the fireship *Spitfire* and (at the year's end) of the sloop *Marquis de Seignelay*.

In 1786 it was decided to found a settlement in New South Wales, and Howe—who since 1783 had been first lord of the admiralty—chose Hunter to be second captain of the *Sirius*. Phillip, who was first captain, was also governor of the new colony, so that Hunter was practically in command of the ship. Shortly before sailing he received a dormant commission as governor in the event of Phillip's death or absence from the colony. While on the Australian station he made valuable surveys of Port Jackson, Botany Bay, and Broken Bay, which are reproduced in the journal of his 1st lieutenant William Bradley, now in the Mitchell Library at Sydney. In 1790 the *Sirius*, after a stormy voyage to the Cape for stores (during which she circumnavigated the globe), was wrecked at Norfolk Island—a disaster for which Hunter was held not at all responsible by a court martial that tried him in 1792. In that year he had returned to England, and after his honourable acquittal busied himself with preparing for publication his *Historical Journal of the Transactions at Port Jackson and Norfolk Island*, which appeared in 1793. He then served in the *Queen Charlotte*, and was thus employed when Phillip resigned the governorship of New South Wales; he at once applied for and gained the appointment, and arrived in Sydney to take up his duties on 7 September 1795, at the age of 58.

The new governor soon realized the difficulties of his position. Since March 1792 the colony had been administered by Francis Grose, commander of the New South Wales Corps, who had substituted military for civil rule and vested the administration of justice in his officers. They promptly took advantage of the situation to further their private interests; their free grants of land were cultivated by convicts supported at government expense, their produce was sold at monopolistic prices to the government stores; they developed trading interests, buying whole cargoes as they were brought into port, and retailing them to the poorer settlers at prices so extravagant that the latter were brought to poverty and often to bankruptcy; they developed the trade in spirits to such an extent that 'rum' became an accepted currency. The effect on a population already deficient in civic qualities was such that Hunter wrote 'a more wicked abandon'd and irreligious set of people have never been brought together in any part of the world.' Hunter set himself immediately to re-establish the authority of the civil magistrates—a course which brought him into conflict with the military officers, already prejudiced against a naval governor; and thereafter under their leader Macarthur they repeatedly disturbed his administration and thwarted his attempts at reform. His efforts to have the Corps replaced by a force of marines had, owing to the exigencies of the war with France, no result.

Against the trading privileges of the officers Hunter could effect little. The poorer settlers solicited his support for a co-operative trading association, and in June 1797 he suggested to the colonial office the establishment of a public store, to be stocked from England with articles that could be sold at a price sufficient to cover costs—payment being taken in grain or stock, if necessary. The colonial office had already on 31 August 1797 despatched the *Barwell* with stores to be disposed of to needy settlers at prime cost; articles remaining in the government store after the requirements for public purposes and for new settlers were met were to be disposed of in like manner. Hunter added 25 per cent to the prime cost, in order to cover overhead expenses, and pointed out that the goods were still very cheap, as the officer-traders had previously charged from 100 to 1000 per cent, and sometimes more, on the cost of articles landed in Sydney. But supplies were forwarded from England somewhat irregularly, and the local opposition was strong, so that this system of public trading did not develop to any considerable extent under Hunter. Indeed in June 1798, no doubt under a misapprehension as to its objects, he went so far as to sanction a 'ring' which the trading officers and their friends organized to entrench their monopolistic position; 'every person' he wrote in a general order of 25 June, 'is desired to keep the possession of their own money until they are apprised by public notice that a cargo has been bought, the officers having undertaken the trouble of officiating as agents for the general benefit of the whole colony.' The delightfully naïve comment of the colonial office on this order was that it might be taken 'as a sanction to officers engaging in traffic'—as if they had not been doing that very thing for years past.

Nor was Hunter more successful in cutting down the expenses of the colony, which had increased considerably under the regime of the Corps. On arrival he found fewer than 20 convicts available for public works, though more than 1000 (of whom seven-tenths were males) were victualled by the government, the officers having taken into their private service as many as 13 convicts each to work their land-grants. On 31 August 1797 the colonial office instructed Hunter to allow only two convicts, maintained at government expense, to each officer. This instruction was nominally enforced from 1 August 1798 onwards, but was apparently evaded with success until King took office. Further, under Corps rule a good deal of public land had been allowed to lie idle, and Hunter did not feel himself able to recall from private to public service a sufficient number of convicts to carry on public works and cultivate public lands. Consequently, during the 22 months ending June 1798 a sum of over £29,000 was spent on grain and pork for government requirements; yet, as the colonial office pointed out, had the convicts victualled at public expense (except the two allowed to each officer) been employed in the cultivation of government land, no grain whatever need have been purchased during this period. Hunter was also confronted with the difficulty of arresting convict escapees who engaged in bushranging on the confines of the settlement, and with the Irish political prisoners, who continuously threatened trouble. The convicts as a whole were unruly, and Hunter had recourse to a system of night-watchmen to preserve order in the town. During this period, too, the colony was visited in 1798-9 by a severe drought and in 1800 by disastrous Hawkesbury floods.

Hunter's best services were rendered in the sphere of navigation, his encouragement of Bass and Flinders being particularly noteworthy. But he was unsuited to his office. The colonial office received direct from Macarthur and 'certain anonymous writers' letters animadverting on the governor's weak administration, and Hunter answered the charges on 25 July 1798 with a

bitter vehemence that must have prejudiced his case. The letter recalling him reached Sydney on 15 April 1800. On the same day Philip Gidley King returned to the settlement, bearing a commission (dated 1 May 1798) which authorized him to take over the government in the event of Hunter's death or absence. Hunter, however, refused to give up office until 28 September, on which date he embarked in H.M.S. *Buffalo* to return to England. Reaching it on 24 May 1801, he immediately demanded an enquiry into the charges made against his administration; none being granted, he proceeded to vindicate himself in several pamphlets, living meanwhile at first on a captain's half-pay and afterwards on a pension of £300 a year. He soon became one of the recognized authorities on the affairs of the new settlement, and his suggested reforms—which were eventually, if gradually, carried out—included a revision of the criminal code, improved law-courts, the establishment of an advisory council for the governor, the introduction of trial by jury and the development of a sound police system. In 1808, as we learn from a letter he wrote to the earl of Galloway, he was asked to go out again as governor, but was not anxious to do so, preferring if possible to serve on a commission to investigate the affairs of New South Wales. He was still deeply interested in the colony—'I have travel'd with a gun on my shoulder through all parts yet known in its interior', he told the earl—and anxious to have it maintained, both as a depot for supplying western South America with British manufactures, and to prevent the French and Spaniards from using it as a rendezvous in the Pacific. In 1809 he devised a lifeboat which for all practical purposes anticipated the modern designs. No further employement came to him, and he died in London on 31 March 1821.

As governor of New South Wales Hunter was not a success, but as a sailor he commanded the consistent respect of his contemporaries. Howe, who had been deceived by his modesty into thinking that he had no ambition, said afterwards 'Had I known that he had other wishes, I would have taken care earlier to have seen to his advancement.' He was, for a naval officer of those days, very well educated, and Falconer the poet and Burney the musician were his friends. To Australia his best gifts were his own accurate surveys and his judicious encouragement of zealous explorers, especially of Bass and Flinders.

See his own *Historical Journal*, his despatches in the *Historical Records of New South Wales* and *Historical Records of Australia*, and the account of his early life in the Naval Chronicle, vol. vi.

W.J.

Hunter, JOHN IRVINE (1898-1924), born at Bendigo in Victoria in 1898 and educated at the Albury district school, the Fort-street high school, and the university of Sydney (M.B. and Ch.M., 1920; M.D., 1924), was probably the most brilliant student that university has yet produced. During his undergraduate career he won practically every prize and scholarship open to him, including the John Harris scholarship for anatomy and physiology and prizes for pathology, operative surgery, clinical surgery, and a surgical essay. In 1919-20 he was demonstrator in anatomy; in January 1921 he became associate professor of anatomy—the youngest professor in any first-class university in the world. After a visit to Europe and America, to study the most recent methods in anatomical teaching and research, he was made in 1922 professor of anatomy at Sydney, succeeding J. T. Wilson (q.v.). Devoting himself especially to the study of the nervous system, he joined N. D. Royle of Sydney in an investigation of spastic paralysis which had remedial results of great value. Stated briefly, his chief discovery related to the functions of the sympathetic nerve system. A few years ago it was believed that this system supplied the involuntary muscles only; but Hunter and Royle discovered, first, that sympathetic nerves were present in voluntary muscles (i.e. muscles whose action can be controlled by the human will), and second, that their function was to stabilize the effect of voluntary muscle action. That is, if the impulse conveyed through a spinal nerve to a voluntary muscle places the arm in a certain position, the work of the corresponding sympathetic nerve is to make the arm keep that position until another impulse arrives. Consequently, if a spinal nerve is injured at any moment, the sympathetic nerve keeps the affected limb rigid in the position it was last impelled to take, and so causes what is called 'spastic paralysis.' Theoretically, therefore, the severance of the sympathetic nerve would release the limb—and Hunter proved experimentally that certain cases of paralysis could be thus cured completely. In June 1924 he and Royle were invited to explain their discovery at a clinical congress to be held in New York in October; and after demonstrating the success of the new methods to an assembly of 2500 surgeons from many parts of the world, and delivering lectures at several universities and medical schools, Hunter went on in November to England to lecture in Cambridge and London. He was, however, by this time worn out and ill, and at Cambridge succumbed to enteric fever, dying in London on 10 December 1924.

Brief as was Hunter's active career, he had already proved himself, in the opinion of Professor Elliot Smith (q.v.), the leading anatomist in the British Empire. In Sydney he was best known as a most lucid lecturer, a very capable organizer, and a lovable colleague; and on 23 December 1924 the senate of the university formally recorded its sorrow in a resolution from which the following passage is extracted:—'In his short life, so greatly lived, he won universal affection by his beauty of character. He rose through his genius, as it were ideally, to represent whatever is best in university training, to become equal with the great anatomist by whom he was taught and whom he succeeded, to inspire the medical school even from his undergraduate days, and to embody the hope of the future for the whole university.'

Hussar. See SNAPPER.

Hutt, JOHN, is first heard of as collector of the North Arcot district in Madras about 1830, and next as a member of Wakefield's National Colonization Society in 1832. When in 1837 it was decided by the South Australian colonization commissioners to recall Governor Hindmarsh, John Hutt was strongly recommended by his brother (one of the commissioners) and other notable men for the vacant post. The influence of G. Fife Angas having secured it for his candidate Colonel Gawler, the colonial office offered Hutt as a consolation prize the governorship of Western Australia, and on 28 April 1838 the two appointments were gazetted together. Hutt reached Fremantle on 2 January 1839, and, as became an associate of the Wakefield-Buller coterie, set himself to systematize the administration of the young colony without paying much attention to the wishes

of the colonists. He consequently incurred a good deal of unpopularity, though most of his decisions were based on sound sense; thus he would not allow immigrants to select land outside certain areas, because concentration of settlement was the only sure safeguard against aboriginal attacks. On the other hand he deliberately set aside instructions issued by the colonial office, early in 1839, to raise the upset price of crown lands to 12s. an acre; when in 1840 he was compelled to obey orders, the sale of crown lands almost stopped. His policy towards the aborigines was marked with friendly zeal, and by the end of 1841 had established harmonious relations with them and almost eradicated crimes of violence. The later years of Hutt's term were an epoch of great depression, mainly because the colonial office policy of enhancing the price of crown lands (in 1843 to 20s. per acre) discouraged immigrants—who could get better land in the eastern colonies for the same price—and reduced the revenue from crown land sales to about £8 per year. From the worst results of such depression the colony was saved by Hutt's caution and circumspection; but these are never popular virtues, and he welcomed the expiry of his term, returning to England early in 1846. He is next heard of as promoting in 1850 a Colonization Assurance Company, which sent more than 100 emigrants to Western Australia, but ceased operations when the colonial office refused to hand over to it the whole management of free migration to that colony.

John Hutt's brother SIR WILLIAM HUTT (1801-1882), who represented Hull in the imperial parliament from 1832 to 1841 and Gateshead from 1841 to 1874, was one of the most important men in the Wakefield circle. He joined the National Colonization Society in 1830 and the South Australian Association in 1834, was made a colonization commissioner in 1835, placed on the waste lands committee of the house of commons in 1836, and joined the New Zealand Association in 1837. In 1838 he and his friends made great efforts to have the land and immigration system of Western Australia assimilated to that of South Australia, but the colonial office persistently postponed its decision. In 1860 he was made paymaster-general and vice-president of the board of trade, and in 1865 negotiated a treaty of commerce with Austria. He died in 1882. The Hutt River, valley, and county in New Zealand are named after him. (P.C., 1860; K.C.B., 1865.)

Hutton, SIR EDWARD THOMAS HENRY (1848-1923), born at Torquay, England, on 6 December 1848 and educated at Eton, entered the army in 1867 (lieutenant, 1871; captain, 1879; brevet major, 1882; lieutenant-colonel, 1889; colonel, 1892; major-general, 1900; lieutenant-general, 1907), and served in the Zulu war (1879), the Boer war (1881), the expedition against Arabi (1882) and the Nile expedition (1884-5). In 1888-92 he commanded a corps of mounted infantry at Aldershot, and in 1893 was appointed to command the New South Wales military forces, with the local rank of major-general. In 1896 he was transferred to Ireland as assistant-adjutant-general, and in 1898 was sent to Canada to organize the Dominion's militia. In the early part of the South African war (1900-1) he had charge first of the mounted infantry under Lord Roberts and then of an independent column in the eastern Transvaal. In 1901 he was, by request of the federal government, sent to Australia to organize the new Commonwealth's military establishment, and it was mainly through his great administrative capabilities that the heterogeneous forces of six States were gradually shaped into a single army. This task completed, he returned to England at the end of 1904 and was given command of the 3rd division and the administrative charge of the Eastern Command. In 1907 he retired, but at the outbreak of the Great War volunteered again for service, and recruited and organized the 21st division of the 3rd (a Kitchener) army. He died at Torquay on 3 August 1923.

Hutton was from the first especially interested in mounted infantry. He raised and organized small forces of his own for the campaigns against the Boers and Arabi, commanded units in 1884-5 (the Sudan) and 1888-92 (Aldershot), and in the South African war led a mounted infantry brigade over 6000 strong, in which Australians and New Zealanders served side by side with British and Canadian troops. During his command in New South Wales he fostered mounted regiments, both light horse and mounted riflemen; he revived volunteering, particularly for 'national' regiments (the Scottish, Irish, English—St. George's—and Australian Rifles); and through his enthusiasm and military ability achieved for the New South Wales troops a much higher standard of training and military knowledge, particularly in the sphere of field operations, than had previously been attained in Australia. His term of service for the Commonwealth produced similar results throughout the Australian forces, and it was on foundations laid by him that all subsequent developments of Australian land defence were based. His interest in Australia was permanent, and he was from 1908 onwards a hearty advocate of the universal compulsory military training system. In 1916 he published *A Brief History of the King's Royal Rifle Corps, 1755 to 1915.* (K.C.M.G., 1900; K.C.B., 1912.)

Hybridization. See PLANT-BREEDING.

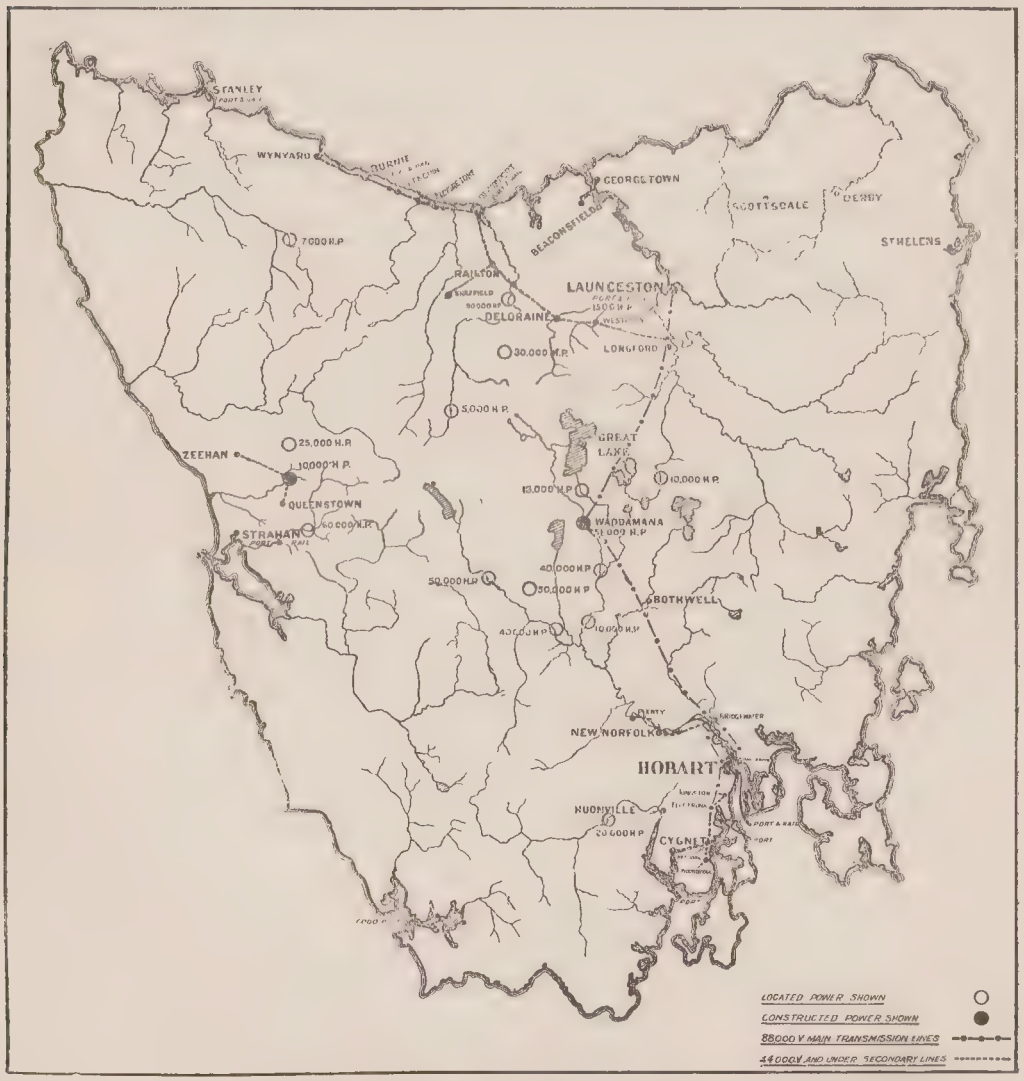
Hydrocharitaceae, a widespread family of aquatic herbs with five genera indigenous to Australia. The young flowers are enclosed in a membranous spathe. The genus *Vallisneria* has one indigenous species, *V. spiralis,* a submerged freshwater plant with a tuft of flat leaves, frequently grown in artificial aquaria. The male and female flowers are on distinct stems; the males numerous, in an oblong spathe, the females solitary, enclosed in a tubular-toothed spathe; petals obsolete. The male spathe is on a short stalk; the anthers when ripe burst the spathe, and the pollen floats to the surface. The female spathe is seated on a spirally coiled stem which unfolds gradually, carrying the flowers to the surface, where they are fertilized by the floating pollen. After fecundation the stalk contracts and draws the ovulary to the bottom, where the seeds mature. The genus *Ottelia* has 2 indigenous species. *O. ovalifolia* is a fluvial herb, with floating leaf-blades and lily-like flowers.

Hydrocotyle, a semi-aquatic genus of the family Umbelliferae, consisting of lowly herbs with minute flowers in small bractless clusters, dispersed over the warm and temperate regions of the earth. Of the 26 species indigenous to Australia 23 are endemic. The calyx-teeth are inconspicuous; petals oval, with a straight apex; fruit without oil receptacles, usually 3-ribbed

and smooth. *H. vulgaris*, a creeping mud-plant with orbicular leaves attached to the stalk by the centre (as in the garden nasturtium) and held horizontally, is the pennywort of Britain.

Hydro-electric Developments. In a continent where distances are great, coal-deposits rare (though rich within restricted areas) and water-power of the ordinary kind almost non-existent—since few rivers can be counted on to give a regular flow of any force worth using—the establishment of factories outside the limited coal-field area is a risky and expensive undertaking. Coal-miners in New South Wales have more than once almost throttled the manufacturing industries of other States, and those States have looked about for relief with more anxiety than skill. Yet in nearly all of them conditions for the successful installation of hydro-electric systems of power-manufacture have been present—the existence of natural or potential reservoirs in elevated areas not far from the chief towns, a plentiful rainfall over those areas, and a lack of serious obstacles to the transmission of the generated power. Little, however, was planned in this direction, and nothing at all was done, until the smallest of the States, Tasmania, showed the way so clearly that a migration of big industries thither seemed possible. Since then other States—even New South Wales, where the coal-fields mainly lie—have considered the establishment of such installations as Tasmania has now been enjoying since 1916. Victoria is for the present planning to derive manufacturing power from her brown-coal deposits at Morwell (q.v.), and has postponed hydro-electric generating stations, which would have to be made farther away from the manufacturing centre at Melbourne.

Tasmania.—In this State the central physical feature is a tableland from 2500 to 3500 feet high, fringed by a range (known as the Western Tiers) which catches the moisture brought along by the westerlies that prevail in the Southern Ocean south of 40° S. lat. As a consequence, while the average annual rainfall for Hobart and Launceston is about 28½ inches, that for



HYDRO-ELECTRIC SCHEMES IN TASMANIA.

the central tableland is from 100 to 120 inches, and is distributed with fair regularity throughout the year. Of the natural reservoirs on this tableland the Great Lake is the largest; but several of them possess the distinguishing feature of a river outlet which after a very few miles drops suddenly into a deep gorge, and the southern part of the tableland is intersected by these almost parallel gorges. In 1908 a private company secured a concession to utilize for the production of power the waters of the Great Lake, but by 1914 its capital was exhausted and it was compelled to suspend operations. At this juncture, the government decided to assume control of the uncompleted scheme, refunding the money already spent. The initial stage of the development, which was completed in 1916, consisted of a 10,000 horse-power installation for the supply of power to Hobart and to manufactories in its neighbourhood. The storage capacity of the Great Lake (which has an area of 50 square miles) was increased by the construction of a masonry dam 644 feet long and 12½ feet high, fitted with 10 sluice-gates. This gave a depth of 35 feet in the lake. The river-bed was used to convey the water for four miles; it was then diverted by a weir into a canal 3½ miles long, leading to a natural depression which has been used to form an intermediate storage reservoir. At the western end of this lagoon (which has a length of 1¼ miles and an area of 340 acres) there is a ferro-concrete penstock chamber, where the water, after passing through suitable screens, enters a woodstave pipe-line 4 feet in diameter and 5500 feet long. At the end of this line two steel pipes, 4300 feet long and 37 inches in diameter, convey it to turbines 1120 feet below. The water is discharged into a wheel pit and then, by way of a tail-race 600 feet long, into the river Ouse.

The power-house at Waddamana is a steel structure, covered with corrugated iron, erected upon concrete foundations. It contains the turbine-driven generating plant and switchgear; immediately outside it and in the open air are the step-up transformers and line switches. The first installation of plant in the building consisted of two turbines of the Pelton-wheel type with a normal rating of 4980 horse-power each while running at a speed of 375 revolutions per minute, coupled direct to 3-phase alternators generating current at a pressure of 6600 volts, with a frequency of 50 cycles per second. Two separate turbine-driven continuous-current generators for exciting the fields of the alternators are also housed in this building; each of these machines is capable of developing 160 horse-power when running at a speed of 150 revolutions per minute. Electrical power from the main alternators is stepped up by oil-insulated and water-cooled transformers to 88,000 volts, at which pressure it is transmitted 62½ miles to Hobart and 17 miles beyond that city to North-west Bay.

The transmission line consists of three 7-strand copper wires, each with a section of .05 square inch, supported by 5-unit suspension insulators from lattice-steel towers 60 feet high, spaced approximately 600 feet apart. Above the conductors a 7/10 S.W.G. galvanized steel ground wire is strung from the apex of each tower to the next. The overhead line from Hobart to North-west Bay is supported with wooden structures made from local timber. At the Hobart sub-station power required for use in the district is stepped down to 11,000 or 6600 volts, according to requirements. The pressure of the supply is further reduced at various sub-stations in the city for tramway, power, and lighting purposes.

By far the largest individual consumer is the Electrolytic Zinc Company of Australia, whose works are situated at Risdon, about three miles from Hobart; zinc is produced there at the rate of about 100 tons per day. Power is also being supplied to the Carbide and Electro-products Company—until recently the Hydro-Electric Power and Metallurgical Company (the private company which initiated the scheme)—for the manufacture of carbide of calcium and carbon electrodes; a sub-station of modern outdoor type has been erected at Electrona on North-west Bay, and about 5000 tons of carbide and 700 tons of electrodes are produced yearly. These works were in 1925 taken over by the government. At Claremont, north of Hobart, the Cadbury-Fry-Pascal chocolate factory is supplied with power.

So successful were the first attempts to supply power that the zinc works alone demanded three times as much as the installation was capable of supplying, and other districts of Tasmania asked why they should not share in the benefits of a national undertaking. Accordingly in 1919 it was decided to enlarge every part of the installation. A new dam, 1182 feet long and 40 feet high, of the multiple arch type, increased the area of the Great Lake to 60 square miles and its depth to 55 feet, and the available water was greatly increased by tapping the Ouse River five miles away and bringing its upper waters to the lake. Canals were widened, more turbines installed, the southern Tasmanian line duplicated, and a transmission line erected to convey current to Launceston. Here the principal consumers are two large woollen-mills. The total available power is now 66,000 horse-power, nearly all of which is sold. Another 15,000 is being developed, and further water-power to the extent of over 300,000 horse-power has been surveyed and designed, and will be constructed as soon as the demand arises.

Altogether Tasmania has seven plants for the distribution of hydro-electric power. The first was erected at Launceston in 1895 to light the town. In 1915 the Mount Lyell Mining Company established a station for its own use at Lake Margaret, where the rainfall is 140 inches a year; 9600 horse-power is available.

Other States.—In Victoria, as has been said, power is in the first place to be derived from the huge deposits of brown coal at Morwell in Gippsland; this scheme is described elsewhere. But hydro-electric schemes have also been considered, and in 1924 work was begun on a group of power-stations at the Sugarloaf in the valley of the Goulburn River, 53 miles north-east of Melbourne. It is further contemplated to derive power, when needed in the future, from stations on storage reservoirs in the Baw Baw ranges 30 miles north of Morwell, and on the Hume dam across the Murray above Albury. In New South Wales high-level lakes are lacking, and the great artificial lake at Burrinjuck (see IRRIGATION) is so far from any existing centres of manufacture that its power-developing capabilities are only just being utilized; though the necessary legislation was passed in 1919, it was only in 1924 that a beginning was made of an installation that will supply power and light to towns along the southern line of railway. Even farther from existing centres, but much more prolific of power, is a suggested installation near

Jindabyne on the Snowy River, where an output of 25,000 horse-power could be obtained without any regulation of the water-supply: the coast (at Twofold Bay) is only 90 miles away, and industries requiring large quantities of power at a low cost could easily be established there. The only important installation actually in use in New South Wales obtains its power from the Nymboida, a tributary of the Clarence River. To construct it the municipalities of Grafton and South Grafton, and several neighbouring shires, were in 1922 combined into a 'Clarence River County District,' which has dammed the Nymboida, tunnelled the range between that river and the Orara, and erected in the Orara valley a power-house that will supply when completed 16,000 horse-power to Grafton and the surrounding townships. Many farmers use current from this source both for lighting and for driving their machinery. A more extensive scheme (the Jackadgery) is being designed, involving other tributaries of the Clarence and eventually providing over 70,000 horse-power for lighting and factories. The Nymboida installation was put into operation in November 1924. The rest of the State is being thoroughly surveyed for hydro-electric purposes, 42 stations having been established on important streams to determine their normal flow and the amount of power obtainable from them.

A proposal to obtain power from the Hume dam near Albury has already been mentioned. Originally a Victorian suggestion, it has been provisionally adopted by the authority (representing the Commonwealth and the States through which the Murray flows) that is constructing the dam; it is further proposed that the Commonwealth and all the States should establish a central committee, with technical advisers, to supervise and standardize all future electrical power schemes in Australia.

In the other States, and in several districts of New South Wales, electrical power is obtained almost entirely from fuel-run power-stations; but schemes for obtaining power from the Barron Falls in northern Queensland, and from dams on the Fitzroy and Dawson farther south —also from the Glenelg River and its tributaries in north-western Australia, mainly for use in connection with the iron deposits at Yampi Sound (see IRON)—were under consideration in 1924. J.H.B.

Hydroid Zoophytes, the popular name of several genera of Hydrozoa, a class of Coelenterata comprising polyps and medusae with ectodermal gonads and no vertical partitions in the enteron. Most of the species are marine, though a few live in fresh water.

The simplest zoophyte is the freshwater polyp (*Hydra*), which is found attached to waterweeds in ponds. It is a delicate little animal, harmless to human beings, green or reddish-brown in colour according to the species; it averages one-third of an inch in length, and consists of a little column with a circle of thread-like tentacles at the summit. When a tentacle touches some small organism, the latter is paralysed, drawn into the mouth at the top of the column and thence into the simple stomach, and digested, the remains being cast out of the mouth. On the tentacles are numerous peculiar cells, each containing a little sac filled with a poisonous fluid as well as a barbed thread coiled up inside. A pointed process projecting from the outer surface of the cell acts as a trigger which, on being touched, causes the barbed thread to be shot out, thereby stinging and poisoning the prey. When once discharged, the stinging-cell cannot be used again, and is cast off and replaced by a new one. *Hydra* reproduces itself sexually by means of eggs, or asexually by forming buds which grow out from the wall, develop mouth and tentacles, and normally become detached. It may also be cut into pieces, when every fragment that contains a portion of both cell-layers will develop into a complete animal.

The sea-firs (*Sertularia, Aglaophenia, Halicornaria,* etc.), are horny, plant-like growths, which often occur in dense masses like miniature forests. In rock-pools they usually form merely fir-like growths on stones or shells; but the species that inhabit deeper water, and are sometimes cast up on our beaches after heavy weather, may attain a height of several feet and branch most luxuriantly. Although on account of their plant-like appearance they are often mistaken for seaweeds, these delicately branched sea-firs are in reality complex colonies composed of numerous little polyps, often so small as to be visible only under the microscope.

All the sea-firs have fundamentally the same structure as *Hydra.* The polyps are of two kinds, one set being in the form of an elongated sac with a crown of tentacles; the other, when mature, resembles a small medusa or jelly-fish. These are really special bodies carrying the generative organs; they originate as members of the fixed zoophyte, from which they are set free by breaking away as little umbrella-shaped bodies. These individuals differ widely from the fixed form, being indeed so unlike it that their origin would never have been guessed if the separation had not been seen to take place. The fertilized eggs of the medusa develop into the fixed hydroid colony. Free-swimming generative polyps or medusae occur only in some zoophytes; in many species the generative polyps remain in the colony and produce their eggs in that situation; some lose their jelly-fish structure to a greater or less extent, and may be reduced to a mere wart. When the generative polyps are free-swimming, the eggs are scattered over a wide area, and not crowded in the neighbourhood of the parent stock; further, the egg-carrying polyp can swim at the surface of the sea where food is plentiful. Sometimes the generative polyp shows a transition between feeding polyp and medusa; the umbrella can scarcely be said to exist, and the medusa, being unable to swim, can only creep about on its tentacles. Such a crawling medusa (*Cnidonema*) has recently been described from Port Jackson. *Tubularia* is a very graceful genus with large, delicate, pinkish, non-contractile polyps protruding from sheaths which cover only the stalks. It is common on buoys and the bottom of boats. *Pennaria* forms a branching colony, the stem of which is black, and the polyps intensely rose-coloured in life.

Australia has an exceedingly rich zoophyte fauna, the coast of New South Wales alone having yielded over 120 distinct species, while 20 species (belonging to 12 genera) have been recorded from Lord Howe Island. The principal zoological explorations and collections which have added to our knowledge of Australian zoophytes have been made by the *Challenger,* the *Thetis,* and the *Endeavour.* E.A.B.

Hymenoptera, a large order of insects including the ants, bees, wasps, saw-flies, ichneumon-flies, etc. Most of the Hymenoptera are beneficial to mankind, since the great majority

of them either prey upon injurious insects, or are parasites that infest and destroy them. Though many of the families have not yet been well studied, some 6200 Australian species have been already described.

Members of this order may be recognized by their peculiar membranous wings, the reduced hind-wing being connected with the fore-wing on each side by a series of small hooklets, so that the two wings act as one in flight. The venation is strikingly different from that of any other order, and a special terminology is used by most workers in it. At the base of the costa of the fore-wing there is a small hard plate, (tegula) attached to the thorax. The first segment of the abdomen is closely attached to the thorax, so that it appears to form part of that region rather than of the hind-body. It is called the propodeum, while the rest of the abdomen is distinguished as the gaster. The mouth-parts are always mandibulate, though a complex tongue may (as in bees) be developed in addition for the extraction of nectar from flowers. The larva is either caterpillar-like, as in saw-flies, or a legless maggot. It changes into a sub-pupa or praepupa, which is followed at the next ecdysis by a true *pupa libera* of very delicate structure.

Parasites are our friends or foes in so far as they tend to destroy man's insect foes or friends respectively. Few insect larvae are free from their attacks. They vary in size from the comparatively large species of *Pimpla, Ophion,* and *Mesostenus* (which attack the larvae of butterflies and moths, and of which only one individual matures from each host), or the curious long-tailed species of *Megalyra* (of which 30 or 40 may be reared from a single timber-boring insect), to the minute Proctotrypidae, of which one or more may be reared on the eggs of other insects. Other minute parasites are sometimes bred in hundreds from a single large larva, such as that of a hawk-moth. Scale-insects and aphides are destroyed by many small ichneumon, chalcid and proctotrypid wasps, and it is largely due to these and to the ladybird beetles (Coccinellidae) that such pests are kept within reasonable limits. Unfortunately many parasitic wasps also attack larvae of the ladybird and of other useful insects.

It is usual to divide the order into two sub-orders of very unequal extent. The sub-order Sessiliventres includes the saw-flies and their allies, in which the gaster is sessile, i.e. attached to the propodeum along a broad base; the larva is of the caterpillar type. Only two species of the Siricidae (horn-tails) are known from Australia; but the dominant family Tenthredinidae, the true saw-flies, is represented by more than 80 species, many of them large and handsome insects. The best known are species of the genus *Perga,* of which about 30 have been described; plate xix, fig. 29, shows *Perga dorsalis,* a handsome insect whose larva is a familiar object in the bush, hanging in masses upon the foliage of eucalyptus saplings, which they often strip entirely of their leaves. Before pupation these larvae travel quite a long way on the ground, and then enter the earth, and spin a huge mass of cocoons close together. Both larvae and cocoons emit a nauseating smell, suggestive of impure eucalyptus oil. Other interesting saw-flies belong to *Phylomastix* and *Pterygophorus. Pt. cinctus* is a beautiful fly, often found replete with honey on garden flowers, and having a larva with a long, sharply-pointed tail.

The Pear Slug (*Eriocampoides limacina*) often infests pear, cherry, and plum trees in Tasmania and the cooler parts of the mainland, and occasionally attacks hawthorn, apple, almond, and apricot trees. The black, slug-like larvae of this saw-fly, if allowed to work unchecked, may cause every leaf on a pear-tree to fall, so that the fruit hangs bare, and becomes sun-baked and worthless. The main damage to the cherry occurs after the fruit has ripened.

The large sub-order Petiolata includes all Hymenoptera in which the gaster is petiolate, i.e. attached to the propodeum by a distinct waist; the larva is a legless grub. It may be divided into four distinct groups:—
(1) Ichneumoniformia, containing all ichneumon-flies and parasitic wasps, except only the Proctotrypidae; the female abdomen ends in an ovipositor.
(2) Vespiformia, including all forms in which the female abdomen ends in a sting, and the pronotum extends back to the tegulae (proctotrypids, ants, flower-wasps, social and solitary wasps, etc.). The hairs of the thorax are simple, or at the most only twisted.
(3) Spheciformia, including wasps in which the pronotum does not extend back to the tegulae, and the trochanter is always one-jointed; the female always has a sting. The hairs of the thorax are similar to those of group (2).
(4) Anthophila, distinguished by the branched or plumose hairs of the thorax, and the form of the basal joint of the hind tarsi, which is thickened or flattened and often densely hairy; the female also has a sting. (See WASPS and BEES).

The numerous families of Ichneumoniformia may be arranged into three super-families, Ichneumonoidea, Cynipoidea, and Chalcidoidea. Amongst the Ichneumonoidea (ichneumon-flies) the best-known families are Megalyridae, Evaniidae, Ichneumonidae, and Braconidae. The first is peculiar to Australia; the other three are fairly well represented here, but the number of species is much greater in other parts of the earth. The Megalyridae (long-tailed wasps) are a small family of less than 20 species. Their larvae are parasitic in the larvae of wood-boring longicorn beetles. *M. fasciipennis* is our best-known species. Evaniidae are mostly black ichneumon-flies, with the gaster inserted high above the hind-coxae. *Evania appendigaster* is an extraordinary species in which the tiny abdomen looks like a mere appendage of the huge, stout thorax. In the Ichneumonidae (true ichneumon-flies) Australia has a number of fine species, of which one of the best-known is *Echthromorpha intricatoria.* Other fine ichneumon-flies frequently met with belong to the genera *Lissopimpla* and *Mesostenus.* The commonest of all are the dull red-bodied, slender ichneumons of the sub-family Ophioninae, very abundant in the bush, and frequently attracted to light; two well-known species are *Henicospilus turneri* and *Exochilum scaposum.* All these are beneficial insects, whose larvae parasitize lepidopterous caterpillars. Braconidae are smaller ichneumon-flies, possessing one cell less in the fore-wing as compared with the true ichneumon-flies. Many of them are prettily coloured. Thirty or more species are known in Australia; plate xix, fig. 30, shows the very charming *Cyanopterus rufus.*

Cynipoidea comprise the various families of gall-wasps, most of which cause galls in plant-tissues. Few species are known in Australia, most of our galls being formed by Homoptera.

Australia is rich in parasitic wasps (Chalcidoidea); some species are very fine, but most are small and inconspicuous. Girault has listed about 2000 species, most of them described by himself from Queensland. He arranges them in 14 families, more than 600 species belonging to the Eulophidae, 400 to the Encyrtidae, 150 to the Pteromalidae, while the Eurytomidae, Callimomidae, Chalcididae, and the two families of fairy-flies (Trichogrammatidae and Mymaridae) average about 100 species each; the other six families have only about 260 species between them. These insects parasitize the eggs and larvae of all kinds of insects, and most of them are on that account to be reckoned as beneficial. Some of the largest species have been bred from the cocoons of bull-dog ants and the larger wasps, while the minute fairy-flies can be bred from the eggs of dragonflies and other insects.

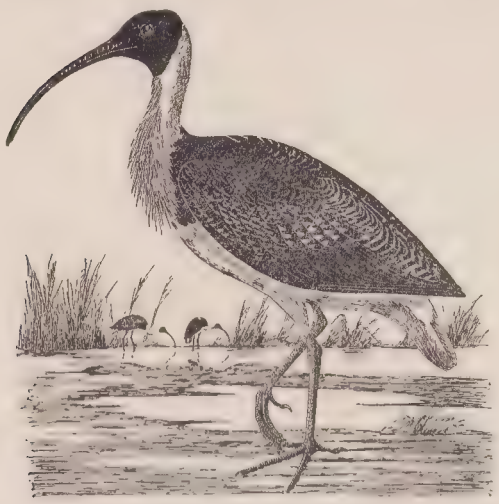
R.J.T.

I

Ibises, Spoonbills, and Storks, large long-legged birds with long necks and bills, constituting (with the herons) the order Ardeiformes; they frequent swamps, lakes and rivers (a few also inhabiting sea-coasts), feed on frogs, crayfish, fish, and insects, and construct nests of sticks, usually in trees, and often in large colonies where various species breed harmoniously together. Four families are represented in Australia: of these the herons are dealt with separately.

Of ibises (Ibididae) Australia possesses three species, the commonest of which is the Straw-necked Ibis (*Threskiornis spinicollis*), unknown outside Australia. This species is less aquatic than the others, visiting cultivated lands and pastures to feed on the grasshoppers that form its principal food. The average number of grasshoppers found in the stomachs of several birds investigated by D. Le Souef proved to be 2000; and he estimated that a flock he found breeding in the Riverina contained 240,000 birds. The great value of these birds for keeping down the grasshopper plague is therefore evident. The White Ibis (*Threskiornis molucca*), common throughout northern and eastern Australia, is nearly related to the Sacred Ibis of Egypt. The Glossy Ibis (*Plegadis falcinellus*) occurs throughout Australia and Tasmania, but is not a common bird; outside Australia it is almost cosmopolitan. A figure of some species of ibis —probably the straw-necked—appears in Dampier's *Voyage to New Holland, 1699.*



Straw-necked Ibis.

Two species of spoonbill (Plataleidae) occur in the swamps of northern and eastern Australia. Their name is derived from the curious form of the bill, which is employed in sifting aquatic vegetation. Both species are white. The Royal Spoonbill (*Platalea regia*) has a black bill and black legs, and usually nests in a swamp, in which it builds a flat, open structure of twigs and trampled reeds: in the Yellow-billed Spoonbill (*P. flavipes*) the bill and legs are yellowish, and the nest, built of sticks and lined with leaves, is placed in a tree.

The only representative in Australia of the stork family (Ciconiidae) is the Jabiru or Black-necked Stork (*Xenorhynchus asiaticus*) which is found throughout the coastal districts of northern Australia, its range extending thence to India. In Australia it is scarce and shy, but very noticeable when present; its black-and-white body, red legs, and large black bill show against the open patches near swamps where a solitary bird often stands silent or walks about for hours on end. It flies well, having a wing-spread of sometimes seven feet. Its nest, constructed of sticks, is a very large structure built in a tree, usually near a swamp.

Illegitimacy. This expression, used in relation to births, implies that they have occurred out of wedlock, and the word 'illegitimates' has been widely but inadvisedly employed to designate children so born. In Australian statistics, however, births occurring among the

'unmarried' (spinsters, or widowed, or divorced women) have for many years been tabulated as 'ex-nuptial' births. This term has the advantage of correctly defining the character of the births in question.

Each State of Australia is characterized by a different ex-nuptial birth-rate, which for convenience' sake may be expressed as a percentage of the total number of births occurring during the same period. Quinquennial averages of these annual percentages follow—figures for 1923 are added:—

Years.	New South Wales.	Victoria.	Queensland.	South Australia.	Western Australia.	Tasmania.	Northern Territory.	Commonwealth.
1901–5	6·99	5·63	6·53	4·17	4·22	5·80	.....	6·05
1906–10	6·70	5·70	7·27	4·21	4·21	5·52	12·75	6·06
1911–15	5·47	5·80	5·96	4·20	4·33	5·32	23·13	5·44
1916–20	4·92	5·51	5·29	3·89	4·00	5·41	22·36	5·01
1923	4·95	4·45	5·40	3·08	3·63	4·44	40·28	4·64

It is, however, by no means certain that these values afford an un-ambiguous measure of the degree of self-control in the several States, as a reduction of the percentage may be due to increased knowledge of contraceptives.

For the whole of Australia, the percentages since 1901 of ex-nuptial on total births have been as follows:—

1901	5·99	1909	6·01	1917	4·91
1902	5·82	1910	5·75	1918	5·23
1903	6·01	1911	5·79	1919	5·30
1904	6·17	1912	5·53	1920	4·84
1905	6·24	1913	5·48	1921	4·75
1906	6·23	1914	5·26	1922	4·49
1907	6·15	1915	5·12	1923	4·64
1908	6·16	1916	4·77		

These figures show that there is a well-defined decrease in Australian ex-nuptiality.

The number of ex-nuptial births per annum per 10,000 unmarried females of ages 15 to 45 (i.e. during the normal child-bearing period), occurring in various countries for the triennium 1900-2 are shown in the following table:—

Ireland	38
Netherlands	68
England and Wales	85
New Zealand	89
Switzerland	98
Australia	133
Scotland	134
Spain	155
Norway	172
Belgium	178
France	191
Italy...	194
Prussia	237
Denmark	242
Sweden	243
German Empire	274
Austria	401

The number of births among the unmarried varies according to age, and attains its maximum for ages 21-22, when it is 181 per 10,000. Among the married the maximum (4835 per 10,000) occurs at 18. Ex-nuptial births are relatively rare at any age, but it is a sociologically important fact that for females aged 16 and under the majority of births are ex-nuptial. Thus for the period 1907-14 the figures for mothers aged 12-16 were:—nuptial births, 1344; ex-nuptial, 2192.

Male births in Australia normally preponderate over female in the proportion of about 105 to 100. In the case of ex-nuptial births the proportion is somewhat smaller; for the period 1901-13 the nuptial proportion was 105.08, the ex-nuptial 104.17. The difference is so small that it may be accidental. The frequency of twins is distinctly less among ex-nuptial births than among nuptial, the rate being 1.023 per cent among nuptial and only 0.768 per cent among ex-nuptial. Triplets, however, are 55 per cent more frequent among ex-nuptial than among nuptial births—but this result depends on too small a number of cases to make it a reliable generalization.

Immigration Restriction. The Australian people are remarkably homogeneous in racial origin, over 97 per cent being of British stock. This homogeneity has been achieved by the adoption of a deliberate policy, gradually evolved, of restricting any large immigration of persons of a markedly different race-stock. Until recent years the only immigrants of different race-stock who sought Australia in considerable numbers were Asiatics; and the policy of restriction—now generally known as the 'White Australia' policy—when adopted by the Commonwealth government in 1901 was directed in fact, though not *eo nomine*, against Asiatic immigration. Such immigrants have in past years reached Australia in two ways: there have been (*a*) an intermittent introduction of Asiatics and Polynesians under contracts of service to settlers, the chief historical importance of which lies in the hostility it aroused among the 'working class' against all Asiatic immigration as the source of a cheap labour supply, and (*b*) movements of Asiatic adventurers into the Australian colonies, the first of which was the rush of Chinese to the Victorian goldfields in the early fifties.

That Asiatic immigration would be considered undesirable by Australians was certainly not anticipated by those who were chiefly responsible for the first settlement. James Matra (q.v.) pointed out on 23 August 1783 that any

number of useful Chinese immigrants might be induced to settle in Australia and to build up its prosperity, as they had in the Dutch Indies, and his suggestion was approved by Sir Joseph Banks. Sir George Young was also of the opinion that the development of the new colony would require only a small flow of population from Great Britain, as most of the settlers would come from the Pacific islands and China. Phillip, however, was not instructed to encourage Asiatic immigration, though he was advised to secure enough island women to serve the needs of the men under his control; he did not act on this advice. Wakefield (q.v.) in his *Letter from Sydney* (1829) reverted to the subject of obtaining Asiatic and island labour for Australia. Labour from this source might, he thought, at first supply the requirements of the settlers; but he pictured the time when Asiatic immigrants (especially Chinese) would convert the 'enormous wilderness' of Australia into a fruitful garden on their own account. In his opinion the only bar to a very rapid increase of the Australian people by means of immigration from China was the difficulty of securing female immigrants from that country. He drew the attention of his British readers to the commercial prosperity they would enjoy when they had a free market with millions of fellow-subjects of Chinese origin. But there was no free movement of Asiatics into the new colony, nor did the settlers make any concerted effort to take advantage of the labour reservoir of the Pacific so long as they had a sufficient supply of convicts. In a few individual cases Asiatics, especially Indians, were employed—for example in 1815 Simeon Lord employed three Bengalis, and in 1819 40 Indian servants were discharged by a bench of magistrates from the employ of William Brown, merchant, and were returned to India. During the thirties, however, the rapid expansion of the pastoral industry created a labour scarcity. In August 1836 John Mackay, an Indian planter of long experience, arrived in the colony, and at once suggested to Governor Bourke that steps should be taken to introduce hill coolies from Bengal, under a system of indenture like that in operation since 1833 in the Mauritius. A second memorandum from Mackay—who had meanwhile been in consultation with a number of pastoralists—was presented to the governor in October; he urged that half the cost of the proposed importation should be met by the government, and half by the pastoralists who received the coolies. The suggestions were widely discussed, and referred by the governor in June 1837 to a special committee of the legislative council, before which one witness stated that his partner in Madras had, two years previously, shipped to Albany in Western Australia a number of Madras coolies who had proved very satisfactory. But the general opinion of witnesses who knew India was that hill coolies from Bengal would be better suited to the pastoralists' requirements. Some suggested that Chinese should also be introduced as gardeners and household servants. There was considerable opposition to the proposal, especially on account of caste systems, paganism and miscegenation. Even its supporters characterized it as a temporary measure devised to meet emergency conditions that were not denied, since it was generally admitted that an immediate supply of 10,000 labourers was required to meet the shortage. In these circumstances the committee recommended that a government bounty of £6 be paid for every male hill-coolie from Bengal embarked before 31 December 1838, providing proper regulations for their transport were made, and 10s. sterling (exclusive of wages) deposited twice a year by employers to form a repatriation fund. By 1839 it would be known whether the experiment was likely to be a success. If a settlement were made to the northward for the cultivation of tropical products, the introduction of Indians on a larger scale would, the committee thought, become necessary. But Bourke was opposed to the scheme, did not consider the report sufficiently favourable to warrant the expenditure of public money, and declined to take official action. Private arrangements were nevertheless made with John Mackay for the introduction of coolies, and in August 1837 a batch of 41 was embarked in the *Peter Proctor*. An indenture-contract preserved in the Mitchell Library shows that they were engaged for five years at five rupees a month, with food and clothing as specified; at the end of their time a free return passage was to be provided if required. No bounty from government funds was allowed on these coolies. Large orders for men were placed in India during 1838, but the only record of arrivals is that of 40 men introduced for the Glenmore distillery. Perhaps, as the *Sydney Morning Herald* complained, 'the ceaseless clamour that was being raised in the colony' against the alleged ill-treatment of those already introduced had actually prejudiced further recruitment. In the following year the government of India (by Act XIV of 1839) suspended contract emigration from its territories, as the result of abuses to which the coolies were subjected in the Mauritius.

In 1837 pastoralists had been prepared to experiment with Chinese as well as with Indian labour, and in September orders were placed in Singapore for a shipment of Chinese coolies, treasury bills to the amount of £1500 being forwarded to cover preliminary expenses. But no shipment took place—owing, it seems, to the loss of the bills. In 1838 arrangements were made by Mackay to introduce Chinese, but his efforts too were unsuccessful. About the same time the *Sydney Morning Herald* gave publicity to a suggestion that labourers might be obtained at small expense from the neighbouring islands; there is no evidence, however, that the suggestion was then followed up. During 1839-40 there was a large inflow of European immigrants to the colony, and the labour scarcity was less urgent; but in 1840 transportation to the eastern mainland ceased, and it became obvious that convict labour must gradually be replaced somehow. On 22 July 1841 James Macarthur presented to the council a petition from a number of 'prominent citizens' for a thorough investigation of the coolie labour problem. There was nothing in the law to prevent the private introduction of Asiatic labour, but its advocates sought financial help from the government. A special committee, with Bishop Broughton in the chair, having reported against a government subsidy, the parties interested held a public meeting on 24 September 1842 at which, on a motion by W. C. Wentworth (q.v.), an 'Association to obtain permission to import coolies and other labourers from the East Indies' was formed. The Indian act of 1839 had been modified to allow a renewal of emigration under contract to the Mauritius; planters in the West Indies were agitating to have their claims considered, and the pastoralists of New South Wales now joined in the cry; and on 5 May 1843 Gipps

forwarded to the colonial office a petition signed by 686 prominent settlers (the inclusion of 104 magistrates was specially emphasized) asking for a concession such as had already been granted to the Mauritius. But the Coolie Association met with opposition both in the colony and in England. The working-men of Sydney made loud complaint against pastoralists who (as Henry Parkes wrote at the time) 'had been accustomed to having the convicts toil for nothing and they cannot bring their minds to paying for that of the free men.' Gipps had already, on 27 March 1843, forwarded to the colonial office a petition signed by 4129 persons opposed to the introduction of coolies, who argued that a grave injustice would be done to the free men who had come to Australia to better their condition, if they were forced into contact with the low-standard coolies of India. Gipps, while admitting the want of cheap labour in the colony, repeatedly declared that he would regret extremely the importation of Asiatics. James Stephen at the colonial office agreed with the arguments of the working-men, and in a minute prepared for Lord Stanley wrote: 'to gain the greatest possible amount of immediate profit on capital at the expense of any comparatively remote disadvantage, however great or however certain, is at once the policy and the calamity of the times in which we live.' Stanley agreed that the concession should not be granted, and that no public money should be spent on the introduction of Asiatics. It should be noted, however, that both the colonial office and the governor, though objecting to the proposals of the Coolie Association, were at the same time devising a project by which the establishment at Port Essington (q.v.) was to be developed by the encouragement of Malay settlers; it had been shown to their satisfaction that the climatic conditions of that settlement militated against the employment of Europeans for agricultural purposes. On 14 March 1844 Stanley approved this project and forwarded directions for the leasing of land to Malays, etc. The settlement was abandoned, however, in 1849.

Its petition having been refused, the Coolie Association could not openly recruit labour in India. Two shipments of coolies, to the number of 86, were introduced in 1844 on the pretext that they were to serve as domestics—who were exempt from the provisions of the 1839 act; at least one surreptitious shipment of 51 coolies was also made in 1846 under disgraceful conditions. But no extensive system could be built up in defiance of the law of India, so employers again considered the substitutes proposed in 1837-8—islanders and Chinese. On 9 April 1847 Captain Kirsopp, acting for Benjamin Boyd (q.v.), reached Twofold Bay with 65 young men from various islands in the New Hebrides group, who were to be tried out at pastoral work. The landing was opposed by local workmen; the islanders suffered considerably from climatic conditions; and there is no evidence that the experiment was repeated.

Attention now turned to China, where contract emigration from the southern seaports to various countries had been carried on since 1845. In July 1848 a consignment of 100 adults and 21 boys was shipped at Amoy for New South Wales through the agency of J. Tait, a coolie-merchant who found his influence as consul for Spain, Holland, and Portugal very useful in his business. The matter was brought to the notice of the governor of Hong Kong by the British consul at Amoy, who asked for extra-legal powers to act should the coolie-traffic at Amoy provoke a public disturbance; there were no serious riots, however, until 1852. The men under contract for New South Wales were engaged for 2½ dollars a month, and boys for a dollar and a half, with food rations 'as specified.' The British consul, though fearing the results of an extension of the traffic at Amoy, considered the experiment favourable for most of the coolies—'the bad portion of the population is provided for, the island is relieved of many thieves, and a good climate and decent support await them.' During 1848-9 270 Chinese were imported into the Sydney district, and 217 Chinese, Klings, and Malays into Port Phillip; but the climate of Port Phillip was unsuited to the experiment, the coolies were unable to do their work, and many of them were finally put into gaol as vagrants in a very distressed condition. Farther north the experiment was more successful, and later shipments were practically all consigned to the Moreton Bay district, though there were isolated cases of the introduction of skilled Chinese elsewhere; e.g. Thomas Glendinning of Melbourne introduced under contract Louis Ah Mouy, a builder, who later became one of the leading Chinese residents in Australia. Governor Fitzroy was advised by the colonial office to discourage the importation of Chinese, and no government bounty was paid on any of the shipments. During the early gold-rush, when white labour was practically unobtainable, pastoralists renewed their efforts to obtain Chinese, but the gold-fever spread to the Chinese themselves. There were, too, other reasons for dissatisfaction with Chinese labour. During the voyage out the mortality rate was high. When they found their wages were below the normal standard of the colony, they rebelled; they were continually absconding; when they were brought before the courts, the lack of interpreters proved an insurmountable difficulty; and their morale suffered from the anti-social circumstances in which they lived. Most were employed as shepherds, but some were set to work for a company on the Great Nugget Vein property. The Brisbane immigration officer was opposed to further importations. In 1854 a select committee on Asiatic labour estimated that 2400 Chinese had been introduced into New South Wales; their figures for Indian coolies, however, are provedly understated, and this number too may be unreliable.

The Chinese being enticed to the goldfields, pastoralists again considered the possibility of obtaining Indians. In 1852 the Madras Indian Emigration Society arranged, with the approval of the colonial office, the emigration of 60 Eurasians to New South Wales, and the experiment was repeated in 1854 when 101 arrived in the colony. In 1854, too, Henry Parkes introduced an additional 25 Eurasians as compositors for the *Empire*—an action which he always carefully (though not always successfully) distinguished from the attempts made by the pastoralists to get coolies. But the Eurasians were bred to city life and did not meet the requirements of the pastoralists, who preferred coolies. On 14 December 1852 Wentworth in the legislative council had proposed that the Indian government should be informed of the need for labourers in New South Wales, and of the desirable conditions that awaited them in that colony; without the co-operation of the Indian government nothing could be done, since Act XIV of 1839 had not been modified in favour of Australia. In the hope that India would yield to pressure Robert Towns (q.v.), acting as agent for a num-

ber of interested parties, made arrangements to send five ships to India for coolies. But the departure of four of the coolie ships roused the opponents of indentured labour to action. On 7 July 1854 Henry Parkes in the legislative council moved (but failed to carry) a number of resolutions against the introduction of 'a coloured or an inferior race for the purpose of temporarily supplying the existing want of labour;' on 15 August he obtained the appointment of a select committee to take evidence on the conditions under which coolies were introduced—the mortality on the Chinese ships had been specially heavy—and on the terms of the contracts, and to consider whether a colonial protectorate should be established to look after the interests of the coolies. But it was evident that no more Chinese could be obtained under contract while the gold-fever continued in California and Victoria; the Indian government refused to allow the emigration of its subjects, and the ships sent by Towns had to seek other cargo; and in these circumstances the committee reported that no official action need be taken in connection with coolie labour proposals.

The question of securing coloured labour was then in abeyance for almost a decade; as gold-digging became less remunerative, there was no great scarcity of labour. Between the early sixties and the advent of the Commonwealth, efforts to secure Kanaka, Chinese, and Indian indentured labour were made only for the tropical and subtropical districts of Queensland, the Northern Territory, and Western Australia. In 1863 67 kanakas were brought to Queensland by Robert Towns, who secured them through the agency of Ross Lewin, a sandalwood-getter and island trader, for cotton cultivation on his estate about 40 miles from Brisbane. In the following year about 54 were obtained by Louis Hope for sugar cultivation. The experiment was repeated by other agriculturists, and by the beginning of 1868 2017 kanakas had been brought into Queensland. But the abuses connected with their recruitment, transport, and subsequent treatment were already so great that the government was obliged to interfere. Under the provisions of the Polynesian act of that year no islanders might be brought to Queensland except by a licensed trader, and the licensee was required under bond to refrain from kidnapping and to return the labourer to his island at the end of three years; he was also bound to produce certificates, signed by a consul, missionary, or other well-known person in the islands, to the effect that the labourers had been voluntarily recruited. A register open to inspection by magistrates was to be kept by each employer. Inspectors were appointed to enforce the act; but they were for the most part magistrates occupied with other duties, their duties and powers were undefined, and inspection was regarded as optional, so that to a great extent the act remained a dead letter. Allegations of cruelty were still made, and in 1869 a committee was appointed to enquire into the working of the act. The committee recommended *inter alia* that a government agent should be carried on each vessel to supervise recruitment; the Queensland government had no authority to intervene in island affairs, and this was the only way in which they might secure some measure of control over the recruiters. It was not until February 1871 that the government, acting under pressure from Great Britain, issued regulations for the appointment of agents—but the agents apparently had a too limited authority, for the abuses continued. The British government was thereupon forced to intervene. During 1871-2 an officer of the British navy investigated charges of kidnapping; this was followed by an Imperial act for the prevention and punishment of criminal outrages upon natives of the islands, and five schooners were built for the navy in colonial ports to enforce its provisions. During the seventies, therefore, the kanaka traffic was controlled by the Queensland act of 1868, the regulations of 1871, and the Imperial act of 1872. In 1880 the Queensland parliament passed a new Polynesian labourers act, which amended and enlarged the provisions already in force; express power was given to the government to appoint agents.

No drastic action was taken until a series of outrages connected with the traffic occurred in New Guinea. As the labour supply in the several groups failed, or the enforcement of regulations became more effective, recruiters shifted their operations from the New Hebrides to the Solomons, thence to New Britain and New Ireland, and in 1884 to the New Guinea coast. It was common knowledge that the traffic was subject to abuse; indeed, Britain had already suffered the humiliation of a rebuke from the German government on this account, German lives having been endangered as a result of the intrigues of recruiters. In 1884 all traffic in arms was forbidden, and in the same year a royal commission was appointed by the Queensland government to investigate recruiting in New Guinea. Its report forced the Queensland authorities to forbid recruiting after 1890; meanwhile the lot of kanakas already in the colony was to be improved by the appointment of inspectors to supervise the conditions under which they worked. In 1891 9362 kanakas were still under contract in Queensland, out of a total 46,387 introduced since the beginning of the traffic. When in 1885 Samuel Griffith passed an act forbidding the importation of kanakas after 31 December 1890, it was hoped that by subdivision of estates, and the judicious encouragement of European immigrants, the sugar industry would survive the gradual withdrawal of kanaka labour. By 1890, however, Griffith was convinced that this hope could not be realized, and that if the sugar industry was to be maintained the prohibition against the further importation of kanakas would have to be rescinded. In 1892, therefore, despite protests from the other Australian colonies and from Great Britain, a resumption of the traffic was allowed under stringent regulations, which, *inter alia*, restricted the employment of kanakas to the cane-fields. Between 1892 and 1900 about 11,000 were taken to Queensland. When the Commonwealth came into being the federal parliament was given power to control immigration; public opinion throughout the continent tended to favour a White Australia policy, and in 1901 the first Pacific island labourers act was passed, empowering the federal authorities to deport any kanaka found in Australia after December 1906. Recruiting ceased in 1904, and preparations were made for the repatriation of those still in Australia; it was agreed that those who had lived continuously in the country for 20 years, those whose return involved risk either to themselves or their families because of a marriage contracted by them, the very old and infirm, and holders of freehold property should be exempt from the provisions of the act. After December 1906 3642 islanders were repatriated at a total cost of £31,473, of which Queensland contributed £17,570.

During the kanaka period planters did not entirely give up the idea of securing labour from Asia, either in addition to or as a substitute for the islanders. In 1874 enquiries were made by interested parties as to the possibility of securing Chinese coolies for the sugar plantations. Under the terms of the Emigration Convention of 1866 (between Great Britain and France on the one hand and China on the other), which was held to be effective by the Chinese government though it had not been ratified by Great Britain or France, Chinese emigration under contract was only permitted by the Chinese authorities if it were officially regulated by an agent of the government of the recruiting country. This obligation the government of Queensland was unwilling to assume. Moreover, in 1875 a great outcry arose in Queensland against the influx of free Chinese to the northern goldfields, and the importation of indentured Chinese would in these circumstances have been impolitic. About the same time attention was again directed to India as a labour reservoir. As early as 1862 an act had been passed in Queensland empowering the government to issue regulations for the introduction and protection of labourers from India. But the terms under which the government of India was prepared to allow contract emigration from its territory were very stringent, and in view of the possibility of an abundant kanaka supply no further action was taken at the time to secure Indians. In 1874 negotiations were revived, but without success. In 1882 Queensland, moved to action by the abuses which had occurred in the kanaka traffic owing to the difficulties of supervision, again approached the government of India and sent a representative to India to carry on negotiations. But there was considerable opposition in the colony both from the Liberal and the Labour groups; negotiations were discontinued, and an act was passed requiring the government to submit to parliament in advance any regulations issued in connection with Indian immigration. In 1886 the act of 1862 was removed from the statute-book.

When the kanaka traffic reopened in 1892, it was (as has already been said) stipulated that the imported labourers should be employed only in cane-fields; and planters, looking round for another labour reservoir to supply the requirements of other branches of the sugar industry, turned to Japan. In 1893 a large consignment of Japanese coolies was landed at Cairns, Townsville, and Mackay. Opponents of the traffic promptly urged in parliament that Japanese indentured immigration was more dangerous to the interests of the working-class and the colony than were the kanakas, since the Japanese traffic was unregulated (at any rate at the Queensland end), no limitation was placed on the kind of work for which the Japanese were indentured, and the terms of the contract were not publicly known. Moreover, the Japanese had a powerful government behind them, which might intervene to protect their welfare. Thomas McIlwraith, then premier, though denying that official encouragement was being given to the introduction of Japanese, admitted that he was in favour of the importation of alien labour for the sugar plantations, and pointed out that the Japanese would be employed only on work that had formerly been done by kanakas. Despite opposition, the importation of Japanese was continued on a comparatively small scale, the labourers being recruited either in Japan or on Thursday Island. During a debate on the subject on 31 August 1894 Hugh Nelson (who had become premier) pointed out that it was difficult to devise a restrictive scheme that would be acceptable to Japan, and ignored a proposal to penalize the importers. Negotiations were then opened with Japan through the British minister at Tokyo, on the basis that Queensland was prepared to become a party to the Anglo-Japanese commercial agreement of 1894, providing its right to regulate the admission of artisans and labourers was admitted by Japan. An agreement on these lines was reached in 1897, but the methods of regulation were not determined to the satisfaction of both parties until June 1899. No emigrant might leave Japan for Queensland without a passport, which would not be issued to labourers or artisans without the previous sanction of the Queensland government; further, private applications for imported labour must be submitted for official sanction. But by this time the whole question of Asiatic immigration to Australia was being hotly discussed all over the colonies, and the Queensland government had no mind to involve itself in turmoil over action that all the non-ministerial parties in the colony strongly opposed; it was therefore decided to refuse all applications for the time being. This decision called forth an immediate protest from the Japanese consul at Townsville, who insisted that his government had agreed to the regulation, not to the prohibition, of immigration into Queensland. Resident Japanese merchants, he said, were suffering from the government's decision, as well as the planters. On 18 November 1899 he suggested that the number of Japanese labourers in Queensland should be limited to the number resident in that year (i.e. four to five thousand); as contracts were completed the vacancies could be filled up by further importations to the limit agreed upon. He urged the government to make a decision as soon as possible, not only because the matter affected the *amour propre* of Japan, but also in the interests of 'the immigration companies whose sole business was to supply Japanese labourers to employers in this country.' In October 1900 the proposal was accepted in principle; the limit was fixed at 3247 (the official figure for resident Japanese labourers in 1898), and it was agreed that not more than 25 should be imported at any one time—a restriction later modified to allow shipments of 50. But importation on these terms came to an end as soon as the Commonwealth immigration restriction act of 1901 came into force.

Between 1870 and 1900 several proposals for the introduction of indentured Asiatic labour were made in South Australia and Western Australia. In 1874 the South Australian government sent an agent to Singapore to engage 200 Chinese for the Northern Territory for two years at three dollars a week or less. The coolies were to be employed either on public works or by private persons as directed by the government resident. A more far-reaching experiment under official sanction was made in 1886-9 when coolies (chiefly Chinese) were imported for the construction of the northern portion of the railway from Palmerston to Pine Creek; the whole of the unskilled work was done by them, as many as 3000 Chinese being employed on the line at one time. There is no record of the number of Chinese introduced on private account. Persons interested in the development of the Territory had since 1874 made several proposals for the introduction of Indians, and in 1879 the South Australian parliament passed an act to

authorize the introduction of Indian labourers into the Territory and to provide for the appointment of immigration agents in India and protectors of Indians in the ports of debarkation. These appointments were designed to meet the requirements of the government of India—which, however, did not consider the safeguards sufficient. More detailed regulations were drawn up in 1882, and a delegate was sent to India to join in the Queensland negotiations; nothing came of this, and a further effort to reach agreement was made in 1890 without success. In 1892 South Australia asked for an intercolonial conference to consider the problem of securing indentured coloured labour for tropical areas; but in Queensland, where the kanaka traffic had recently been resumed, the proposal was rejected.

In Western Australia attention was mainly given to the introduction of Chinese. The colony was not originally established as a convict settlement, and during its early years there were several shortages of labour; suggestions for the importation of Asiatics were made and they were probably introduced in small numbers. From 1850 to 1868 convicts supplied labour for the colony, but when transportation was abolished the cry for labour again arose. In 1874 a committee, appointed to consider the introduction of indentured Asiatics for the development of the pearling industry and of pastoral settlement, reported unfavourably on Indian labour, but advised the introduction of Chinese on a small scale. Following on this recommendation, Chinese were introduced unsystematically during the seventies at public expense. In 1880 the legislative council decided to allow an extension of the system; and, despite local opposition and protests from the eastern colonies, a few hundred Chinese were introduced annually during the eighties under the imported labourers registry act of 1884. This act provided for the registration of imported labourers, for the exclusion of those who, being old or infirm, might become a public charge (a number of Chinese were already being supported by public funds), and for the welfare and comfort of those imported. In 1893 importation was suspended because of local opposition, but was resumed in 1897 for areas north of 27° S. lat., in the proportion of one coolie to every 500 tons of shipping. In 1894 repatriation of coolies at the end of their term was made compulsory. In 1901 further importation was prohibited by federal law.

There is no indentured coloured labour in Australia to-day, except in the pearl-fisheries. This industry is mainly carried on from Broome in Western Australia and Thursday Island in Queensland, and to a lesser extent from Port Darwin in the Northern Territory. When the Commonwealth came into being, experiments were made with the substitution of white labour for the Japanese, Papuans, and Malays who by the end of last century had practically monopolized the pearling industry; these, however, were unsuccessful. Asiatics may indenture for the fisheries under special permits.

Unindentured Immigration of Asiatics.—Until the fifties of last century a few Chinese mechanics and merchants were the only unsought Asiatic immigrants Australia knew of: but as soon as news of the gold discoveries circulated in the southern seaports of China widespread interest was aroused, and many enquiries were made by men anxious to seek the diggings. Chinese speculators were always willing to extend to Australia the 'credit-ticket' system already in operation to Malaysia and California—a system under which the cost of transport was advanced at an exorbitant rate of interest (usually on the security of the persons of the debtor's relatives), and on the understanding that the creditor through his agents should exercise control over the debtor's activities until principal and interest were paid off. By 1854 about 2000 Chinese had congregated on the Victorian fields. Almost at once the European miners agitated against the 'influx.' They complained that Chinese mining methods prevented the ground from being reworked; they were jealous of the economic advantages which the Chinese gained, chiefly by their elaborate organization; they feared that the alien mass would increase beyond the control of the white community. A royal commission of 1855 recommended that Chinese immigration should be restricted by placing a limitation on the number of passengers that a vessel might carry, and by the imposition of an entrance tax, and in June an act gave effect to these recommendations. The number of Chinese passengers that a vessel might bring to the colony was limited to one for every ten tons of registered tonnage, and on every Chinese immigrant an entrance tax of £10 was imposed; the governor was also empowered to collect an annual residence fee from the Chinese to meet the cost of the 'protectors' who were appointed to look after their interests. The restrictive terms of the act were easily evaded by landing immigrants at Guichen Bay in South Australia, whence they walked overland to the Victorian fields. The number of Chinese in Victoria at the census of March 1857 was 25,424, but it was known that many who were moving about the colony had not been included in this figure; the colonial secretary, indeed, estimated that in June of that year there were 33,694 Chinese in the colony.

Meanwhile the agitation against the Chinese continued, and on 4 July a determined effort was made to drive them from the Buckland River field by the destruction of their property and attacks on themselves. An anti-Chinese league was formed next day by the Buckland miners, who invited the co-operation of all Victorian miners; but a general uprising was prevented by the firm action of the government, which despatched troops to the disturbed district. It was evident, however, that a recurrence of the trouble could only be prevented by further restrictions. Victoria therefore invited South Australia and New South Wales to pass restrictive acts on the lines of the Victorian act of 1855. The South Australian government did so, and early in 1858 a bill was introduced into the New South Wales parliament, but was rejected by the council. Victoria also passed in 1857 an act imposing a licence-fee of £1 (payable every two months) on every male adult Chinese miner; the proceeds went to pay the salaries of additional protectors, the cost of sanitary improvements at Chinese camps, etc. Chinese residents petitioned against the imposition of a residence tax, and begged the government to spare those already resident on the fields, whatever course might be taken to restrict further immigration. They were supported by the mercantile community, to many of whose members the transport of Chinese to Victoria had proved lucrative. In the end the acts of 1855 and 1857 were repealed by an act of 1859, which imposed a tax of £40 on Chinese arriving by land, and reduced the residence tax to £4 per annum. As a result of these measures the

number of Chinese in Victoria decreased from 42,000 in 1859 to 20,000 in 1863.

Many of the Chinese who had left Victoria congregated in New South Wales, which at the beginning of 1861 had (by census figures) a Chinese population of 13,000. As in Victoria, the influx was opposed by the European miners. In December 1860 there was a serious disturbance at the Lambing Flat diggings on the Burrangong field, and the Chinese were despoiled of their property and driven away: a second riot followed in January-February 1861, but ended with the arrival of the military and the departure of the Chinese to other fields. In September the government passed an act providing for restrictions on the lines of the Victorian act of 1855 and disqualifying Chinese for naturalization. This raised an important international question. The Convention of Peking, which had been signed in the previous year between Great Britain and France on the one hand and China on the other, besides conferring on the subjects of the contracting parties certain treaty-rights, included a special article on migration which had been inserted at the instance of Great Britain and France. Formerly emigration from China, though rarely impeded, had been technically illegal, though in 1859 the governor of Kwangtung had officially allowed it from that province. In order that British schemes for the operation of the system of contract emigration under official regulations might be developed, it was now declared in clause 5 (of the British version of the treaty) that 'Chinese choosing to take service in British colonies or other parts beyond the sea are at perfect liberty to enter into engagements with British subjects for that purpose and to ship themselves and their families on board any British vessel at any of the open ports of China.' It was thought that the ratification of this convention might affect the situation in New South Wales; but, though the colonial office objected to discriminative legislation which disqualified Chinese for naturalization, and considered any restrictions 'highly objectionable in principle,' the New South Wales act was nevertheless confirmed because of the 'exceptional nature of Chinese immigration.'

The agitation now died down, and, when the natural yield of the goldfields decreased, the acts were repealed by South Australia in 1861, Victoria in 1865, and New South Wales in 1867; nor did the 'Chinese question' again excite public interest until the rich goldfields of northern Queensland were opened up in 1875. Before the end of that year 7000 Chinese had taken out licences to work on the Palmer diggings. The European miners, already considerably outnumbered, secured the support of the southern workers, who opposed the immigration of Chinese because of recent proposals made by interested parties to import them under contract. Consequently in 1876 a goldfields act amendment bill was passed by the Queensland legislature, providing for the imposition on Asiatic and African aliens of a heavier fee for leave to mine or carry on business at the goldfields than was imposed on Europeans. Governor Cairns considered that this attempt to restrict immigration by discriminating against men already resident in the colony infringed the treaty-rights of the Chinese. He therefore reserved the bill; and the colonial office upheld his action on the ground that, although the fifth article of the convention of Peking referred only to Chinese emigrating under contracts of service, nevertheless 'the article contemplates that all Chinese subjects should have full freedom of entry into British dominions without special restrictions or impediments.' The assent of the Crown was therefore deferred. The despatch conveying this decision was angrily received in Queensland; the resident Chinese now totalled about 17,000, and it seemed as if the permanent interests of the colony were to be subordinated to the commercial ambitions of Great Britain. The agent-general in London was instructed to inform the colonial office that, though the people of Queensland valued the privileges they enjoyed as British subjects, nevertheless 'if we are called on to sacrifice our hopes of perfecting a community founded on the principle of social and political equality, we are not content to do so without a most earnest effort to avert such a calamity.' Meanwhile John Douglas, then premier, sent a circular letter to the other Australian governments asking for their co-operation, but they had at the moment no Chinese problem of their own, and public opinion was indifferent; Graham Berry, the premier of Victoria, agreed that 'the rights and responsibilities of self-government as possessed by law should be jealously guarded,' and Henry Parkes in New South Wales was prepared to back any 'well-devised and temperate measure.' Despite the general lack of support Queensland again (1877) passed the original bill with a few minor amendments, and enacted a Chinese immigration restriction bill on the lines of the Victorian act of 1855—with the added provision that the entrance tax would be returned if the immigrant left the colony within three years and had not during that period become a charge upon public funds. These acts were confirmed by the Crown, and during the next five years only 500 arrived in the colony.

Four colonies had thus dealt with the 'Chinese question' at different times, and had solved it temporarily by the adoption of similar restrictive measures. But there was as yet no fixed Australian opinion against the principle of Asiatic immigration. This developed first in the organized trade unions, which in the past had opposed all proposals for the importation of Asiatic indentured labour, just as they had opposed a renewal of transportation—and for the same reasons; they also opposed the immigration of free Chinese because their standard of living was lower than the Australian standard. But the opposition so far had no pan-Australian significance. In 1878, however, the Australasian Steam Navigation Company decided to employ Chinese seamen in some of their vessels. The company had its headquarters in Sydney, and as the vessels returned to port the crews were called out on strike by their union officials. The strike was supported by the unions in Queensland, New South Wales, Victoria, South Australia, and even New Zealand, and monetary assistance was generously provided. In Queensland, moreover, the government gave notice in January 1879 that the mail subsidy paid by it to the company would be discontinued. Under such conditions the strikers were able to hold out until the company practically ceded their demands and promised to withdraw the Chinese gradually. So strong had been the feeling aroused in the eastern colonies by the issue, and so obvious was the value of co-operation, that arrangements were made for the holding of an intercolonial trade-union congress in 1879. This congress *inter alia* condemned any import-

ation of Chinese workers, and called upon the government of New South Wales to restrict the immigration of Chinese by the imposition of an entrance tax. It was followed in 1880 by a conference of colonial premiers, to which Henry Parkes submitted a motion 'that in the opinion of this conference the grave consequences which must follow the influx of large numbers of Chinese call in a special manner for the concerted action of all the colonies, both in representation to the Imperial government and in local legislation.' At the time there was no special influx of Chinese into any of the colonies, but it was feared that the action taken by the United States to exclude Chinese immigrants would divert the tide to Australia. In Sydney an anti-Chinese league had been formed in the previous April, and there was sufficient agitation to induce the premiers to agree to introduce restrictive legislation. When their conference reassembled in January 1881 it protested against the decision of the Western Australian government to increase the importation of Chinese under contract. Subsequently acts restricting the number of Chinese passengers a vessel might carry to one passenger to 100 tons shipping, and imposing an entrance tax of £10 on each Chinese immigrant, were passed in Victoria and New South Wales, despite strong opposition from the legislative councils. In Victoria Chinese aliens were also debarred from voting at municipal or parliamentary elections. In South Australia the bill was modified to allow vessels to carry one passenger to 10 tons shipping, and to exclude the Northern Territory from its provisions. Queensland increased the stringency of its restrictive measures in 1884, when the passenger limitation was raised to one passenger to 15 tons shipping and the entrance tax to £30. Western Australia did not adopt a restrictive policy until 1886, and then only for Chinese not imported under contract. Tasmania fell into line in 1887. The colonial governments were apparently satisfied with the measures adopted, since the subject was not discussed officially at the colonial conference of 1887.

It must not be supposed that Australian opinion was already unanimous in favour of restriction. To Anglo-Australians like George Reid there was not 'the slightest doubt that the mere fact of treaties of friendship and commerce . . . . makes any measure of this kind a violation of the spirit if not of the letter of those arrangements.' There were others who still believed that the rights of man included freedom of migration. Interested capitalists maintained that without Asiatics the development of the semi-tropical areas of Australia would be impossible. But the 'White Australia' party was gaining ground.

Then occurred the crisis of 1888. Since the signing of an emigration convention in 1866 the Chinese government had taken a more active interest in its emigrants, and in 1887 a Chinese commission was directed to enquire into the conditions under which they were living in various European colonies. In May the commission visited Australia. When its report was presented, the Chinese ambassador in London was directed to protest to the foreign office against the 'exceptional and exceptionable laws' which some of the colonial legislatures had enacted against Chinese subjects. The Chinese note was forwarded by the colonial office to the Australian colonies early in 1888 with a request for explanation and comment. It was received with alarm and indignation. In January the government resident in the Northern Territory had called the attention of the South Australian government to the 'exceptional influx' of Chinese immigrants expected there within the next few weeks. A large number of Chinese had already been imported to work on the railway; it was now rumoured that thousands more were coming to exploit the ruby fields. There seemed good cause to fear a peaceful invasion and effective occupation. Parliament being in recess, the South Australian government issued a proclamation imposing a £10 entrance tax on all Chinese immigrants into the Northern Territory; all vessels from China were also to be placed in quarantine for 21 days—an order which resulted in the diversion southwards of several vessels originally destined for the Northern Territory. Meanwhile, the anti-Chinese party in the Northern Territory had sent an agent to the eastern colonies to arouse sympathy for their cause. About the same time the protest from the Chinese ambassador in London was received. There was a widespread belief in the colonies that Chinese emigration to Australia was about to take, with the approval of the Chinese authorities, a new and systematic form. When news of the approach of the *Afghan*, with a large Chinese passenger-list, was received in Melbourne, there was almost a panic, and the fear of an approaching 'invasion' was undoubtedly genuine. On 1 May a large public meeting held in the town hall agreed that the entrance tax ought to be raised to £100. The government, however, was able to deal with the incident under cover of the law. The *Afghan*, which measured only 1439 tons, was carrying 268 passengers; some of these presented naturalization certificates, but they were declared fraudulent, and the captain was given the option of taking the unfortunate immigrants to sea again or of paying the heavy fine he had incurred by carrying so many passengers in excess of the number allowed by law. He chose the former course, and made for Sydney, where the *Tsinan* with 204 Chinese passengers was already in the harbour; and two other immigrant vessels followed soon afterwards. The then premier, Henry Parkes, yielded to the demands of an agitated public and forbade the landing of all immigrants except those who had *bona fide* naturalization papers; for this action he obtained a parliamentary indemnity on the following day. Some of the Chinese held exemption papers showing previous domicile, and on behalf of these a writ of habeas corpus was obtained and they were allowed ashore. All others were excluded. Panic legislation providing for the imposition of an entrance tax of £100 on Chinese immigrants, and raising the passenger limitation to one passenger to 300 tons shipping, was rushed through the house of representatives, only to be held up by the council. Feeling against Britain ran high during this period, on the ground that the foreign office should have concluded with China an immigration treaty similar to that negotiated by the United States. But this was unfair; the foreign office could not act until it was fully informed of the situation in Australia, and some colonial replies to the Chinese note were not received in England until June. Meanwhile the Chinese ambassador protested against the 'arbitrary and irregular proceedings of the colonial authorities,' and demanded compensation for any losses sustained by Chinese immigrants. In the circumstances the colonial office welcomed a suggestion of the South Australian government that an intercolo-

nial conference should be held to consider the question in all its aspects. In June 1888, therefore, the Australian premiers met in conference; they had before them a telegram from the colonial office reminding them of the political and commercial relations of the Empire with China, and suggesting that they should meet the difficulty that had arisen by devising a measure 'equally restricting immigration into the colonies of all foreign labourers, with power of relaxing the regulations in certain cases.' If the colonies desired the negotiation of a treaty, they must not prejudice their case beforehand. The conference, however, rejected the proposal for general legislation, and decided that bills should be introduced to raise the passenger limitation to one passenger for every 500 tons shipping, and that the entrance tax should be dropped. Tasmania alone dissented. Henry Parkes, who had already introduced in New South Wales a bill sanctioning a poll-tax on immigrants, promised that the colony would fall into line when two other colonies had adopted the proposed measure—a promise which was not carried out. The premiers were determined to secure immediate restrictive legislation, but wanted a treaty also. The British ambassador at Peking was accordingly instructed to approach the Tsung-li Yamen with a view to obtaining a treaty similar to that negotiated by the United States; at the same time instructions were sent to the governors of Hong Kong and the Straits Settlements to suspend Chinese emigration to Australia. But the negotiations came to nothing, for a treaty was no longer necessary. As far as the colonies were concerned, the acts passed in 1888 proved effective. Moreover, in any future emergency they could act under the authority of a privy council decision—in the appeal of Musgrove *v.* Chun Teong Toy against a decision of the supreme court of Victoria. Chun Teong Toy, a passenger in the *Afghan* which had been turned away from Melbourne, had sued the collector of customs for refusing his proffered entrance tax and prohibiting his landing. The defendant denied that the money had been offered; but his contention was that, even had it been offered and refused, it was within the power of the Victorian government to exclude aliens from any Victorian port. Even if the exclusion were in excess of the Victorian government's powers, he maintained that this was not a question to be raised by an alien. The supreme court of Victoria decided that only the express powers stated in the constitution act of 1855, with such additions as were strictly necessary to give effect to those powers, had been vested in the colonial government; damages were therefore awarded to Chun Teong Toy. Before the privy council the appellant (the collector of customs) maintained that by the constitution act of 1855 and act 91 of 1859 a complete system of local responsible government had been established in Victoria, carrying with it such use of the crown's prerogatives as was required for local purposes, and especially for the preservation of the public peace. The privy council upheld the appeal.

Chinese immigration into Australia was now effectively restricted. Almost at once the colonists became aware of a thin stream of immigrants flowing into their midst from other parts of Asia. By 1891 there were, exclusive of Chinese, 2503 Asiatics resident in the several colonies, of whom 1800 were Indians, and a few Japanese. After 1893 the desirability of extending the Chinese restriction acts to all Asiatics was frequently discussed in public meetings, and occasionally in parliaments. The importation of Japanese by sugar-planters in northern Queensland increased the antagonism of the Labour party, and the intercolonial conference of premiers which met in 1896, to consider whether they should become parties to the Anglo-Japanese treaty of commerce and navigation (1894), agreed not only to reject the treaty but also to extend the provisions of the Chinese restriction acts to all Asiatics. Queensland alone dissented, and in 1897 became a party to the treaty under a proviso which reserved to the colony the right to restrict the immigration of artisans and labourers. New South Wales, South Australia, and Tasmania at once passed bills on the lines agreed upon, but they were vetoed by the crown. The proposed restriction of Indian immigration affected the unity of the Empire. The question of intra-Imperial migration had already been raised in connection with Indian immigration into Natal, where M. K. Gandhi was rousing Indian opinion against restriction. Moreover the *rapprochement* between Great Britain and Japan, which later developed into the Anglo-Japanese alliance, was already being fostered, and no colonial action that might impair these good relations could be allowed. The immediate and emphatic protests which had been made against the bills by Japan could not be ignored, especially as the Japanese government declared its willingness to negotiate a treaty providing for the restriction of Japanese immigration into the colonies.

The question was discussed at the colonial conference held in London in 1897, whereat Joseph Chamberlain, then colonial secretary, expressed the sympathy of the British government 'with the determination of the white inhabitants of these colonies, who are in comparatively close proximity to millions and hundreds of millions of Asiatics, that there shall not be an influx of people alien in civilization, alien in religion, alien in customs—whose influx, moreover, would most seriously interfere with the legitimate rights of the existing labour population.' But he asked the premiers to consider whether they could not achieve their purpose by a method less objectionable than the exclusion of immigrants on the grounds of colour or race; 'it is not because a man is of different colour to ourselves that he is necessarily an undesirable immigrant; it is because he is dirty, or he is ignorant, or he is a pauper, or he has some other objection which can be defined in an act of parliament, and by which the exclusion can be managed with regard to all those whom you really desire to exclude.' He submitted to the consideration of the Australian colonies an act recently passed in Natal, which embodied the principle of restriction by means of an education test. Any person who, when asked to do so, failed to write out and sign in a European language an application for admission in a form set out in a schedule to the bill was declared a prohibited immigrant. The Natal act had been allowed by the crown, and New South Wales, Western Australia, and Tasmania readily adopted the language test.

By 1901, though there was no general agreement as to the method of restriction, the principle was approved of by a large majority of Australians. The first federal parliament therefore set itself to give effect to the popular demand for the exclusion of Asiatics, and after much controversy the language test was agreed upon. Under the immigration restriction act (No. 17 of 1901) which embodied the 'White

Australia' policy, an immigrant might be required to write out at official dictation a passage of 50 words in any European language. It was understood from the first that European immigrants would not be required to pass the test. The Japanese government protested against an education test in any European language, considering that this distinction placed Japanese on an inferior footing; to soothe Japanese susceptibilities an amending act (passed in 1905) provided for the substitution of 'any prescribed language' for 'any European language.' But no regulations have been drawn up prescribing any language, so that the provisions of the original act are still *de facto* in force. A further clause in the amending act of 1905 legalized an informal arrangement, made in the previous year with Japan and India, for the admission of students, merchants, and other visitors on a passport system; in 1912 the same concessions were offered to China. Under the original act the officer in charge at any port is allowed, on receipt of a deposit of £100, to admit for a temporary period an immigrant who fails to pass the dictation test. Exemption is also granted to the crew of any vessel during its stay in an Australian port; but, if any of the crew who would be prohibited as immigrants do not rejoin the vessel, the master, owners and charterers become liable to a penalty of £100 for each prohibited immigrant conveyed to the colony. Asiatics indentured for the pearl-fisheries are exempted from the provisions of the act.

In the administration of a law which, owing to its many exemptions, was necessarily complex, and was made more complex because it was an attempt to achieve indirectly an object which could not be attained directly without hurting the feelings of friendly nations, it was natural that awkward and occasionally unpleasant incidents should occur. The customs officials in whose hands the administration lay were not always competent to handle delicate situations, so that a few immigrants were at first illegally detained or subjected to unnecessary hardships. Many Europeans who might have become immigrants were dissuaded by the belief that the dictation test might be applied to them, as from the purely legal point of view it could have been; but it must be remembered that this test was forced on a reluctant Australian government by the colonial office for diplomatic reasons, and that prime minister after prime minister publicly disclaimed in parliament and elsewhere any intention of applying it to Europeans—nor has it ever been so applied. Again, the exclusion policy was in parliament a matter of party politics, though the Australian public was every day more emphatic in its favour; such incidents as did occur, therefore, were given full publicity and sometimes exaggerated in the partisan press. The most notorious of these incidents was the *Petriana* case, which deserves mention here just because a distorted account of it was widely circulated throughout the British Empire. The *Petriana*, an oil-carrier from Borneo with a crew of Chinese and Malays, was wrecked off Point Nepean in Port Phillip on 28 November 1903. On the 30th efforts to float her were abandoned; the crew was brought to Williamstown in a tugboat, embarked during the afternoon in a Japanese mail-steamer, and left for their homes (in Borneo or China) on 2 December. This procedure was the outcome of several conversations between the *Petriana's* agents and the under-secretary for external affairs, who was in touch with the prime minister, and who informed the agents that 'provided the men were placed in some situation where they might be kept under supervision until an opportunity arose for their deportation, no objection would be taken to any merely technical infringement of the law.' The government offered accommodation at either of the two Victorian quarantine stations, which were at the time empty; the agent's representative refused, but suggested that it might be possible to arrest the crew as prohibited immigrants and so detain them in gaol; this suggestion was promptly rejected, and the under-secretary in his turn suggested that they should be at once embarked in the Japanese vessel in which passages had been engaged for them. This was immediately done. Unfortunately federal elections were to be held on 16 December, and during the intervening fortnight many totally false statements appeared in the partisan press—one even attributing to the government the proposal to gaol the crew. Unfortunately these sensational absurdities gained a world-wide circulation.

On the whole the policy of Asiatic exclusion, except for exempt classes, has been effectively enforced. Since the inauguration of the Commonwealth the Asiatic population of Australia has decreased; in 1901 47,014 Asiatics were resident, but in 1921 there were only 28,087, including 17,009 Chinese, 2860 Hindus, 2856 Syrians, 2738 Japanese, and 1083 Malays.

Other Restrictions on Immigration.—Though the most important provisions of the act and its amendments especially affect Asiatics, federal officials are empowered to exclude from Australia certain other classes of immigrants whose presence in the community would have an injurious effect upon its welfare. These include anyone suffering from a physical or mental infirmity, or who from any other reason is likely to become an economic burden upon the community; anyone who has within three years been convicted of an offence (not being a mere political offence) and has been imprisoned for one year or longer therefor and has not received a pardon; or any prostitute or person living on the proceeds of prostitution. The original act further prohibited the entrance of immigrants under contract or agreement to perform manual labour within the Commonwealth except (*a*) crews of coasting vessels employed at the ruling rate of wages, (*b*) persons exempted by the minister as possessing special skill needed in Australia. This additional prohibition was placed in the act by Labour influence, reports having reached Melbourne that there was a large influx of contract immigrants to Western Australia for work in the mines and to Queensland for work on the cane-fields. Its administration caused even more trouble and discontent than the exclusion of Asiatics. It was sometimes taken by critics as applying to domestic servants, sometimes to workers of all kinds so long as they came out under contract—both interpretations being, of course, incorrect and invariably repudiated by the government. It was challenged by employers of labour as an interference with freedom of contract, and often obeyed with the utmost recalcitrance. The incident which occasioned most comment was that connected with six hatters who left England under contract to a Sydney manufacturer before the act became law, and had therefore obtained no permit to land. During the voyage the act came into force, and on arrival their permit was demanded. Their employer objected to the

demand, and the men were detained aboard until he complied with the law. Exaggerated stories, representing that they had been expelled from the Commonwealth, went the rounds of Europe. Owing to these and other misunderstandings the Deakin ministry in 1905 introduced a separate measure to deal with contract immigrants, and so worded it that the mistakes due to vagueness of language could not be repeated. Under its provisions the admission of immigrants under contract to perform manual labour is permitted only if the contract is in writing, is made by or on behalf of some person named who must be resident in Australia, and is approved by the minister. Such approval—which must be obtained before the immigrant lands in Australia—will not be given if the contract is made to affect an industrial dispute, or if the remuneration and other terms offered are not as advantageous to the immigrant as those obtaining for workers of the same class at the place where the contract is to be carried out. If the proposed immigrant is not a British subject born in the United Kingdom (or a descendant of such a person), the employer has also to show to the satisfaction of the minister that it is difficult to obtain a person of equal skill and ability in the Commonwealth. If a contract labourer is introduced into the Commonwealth contrary to the provisions of the act, the contract is void, and the immigrant and employer are both liable to penalties; the employer may also be required to maintain the immigrant until he obtains employment, or to pay his return expenses to his country of origin.

Additional restrictions were introduced by an amending act which came into operation on 2 December 1920. It prohibits the entry of (*a*) any person who advocates the overthrow by force or violence of the established government of the Commonwealth or of any State, or of any other civilized country, or of all forms of law, etc.; (*b*) for a period of five years, any person of German, Austro-German, Bulgarian, or Hungarian parentage and nationality, or Turk of Ottoman race; (*c*) any person over 16 years of age who, on demand by an officer, fails to prove that he is the holder of a valid passport; (*d*) any person who has been deported under any act.

Within the last two or three years it has become evident that Australia must expect an increasing immigration from Europe consequent upon the restrictive policy adopted by the government of the United States. Though the provision for a language test in the immigration act was couched in general terms, it was definitely stated by more than one prime minister that European immigrants would not be subjected to it. Providing they satisfied the medical authorities and were not contract immigrants the entry of most Europeans into Australia was unrestricted until quite recently. Small groups of Maltese had entered the Commonwealth before the war without administrative interference; but in 1916 rumours were circulated in Australia that an effort would be made by interested parties to introduce 'cheap labour' to take the place of the men withdrawn from industry for active service abroad. Soon after the rumours became current, a French mail-steamer was reported off Fremantle with about 200 Maltese immigrants aboard. W. M. Hughes, then prime minister, being anxious not to prejudice the conscription issue then before the people, informed the captain of the vessel that the immigrants would not be allowed to land; and so for almost six months the unfortunate Maltese, taken first to New Caledonia by arrangement with the French government and later brought to Sydney and detained on a hulk in the harbour (no transport being available to return them to their country of origin), suffered much distress until they were finally admitted under certain guarantees of employment. The incident roused much public hostility, and the government decided that no more Maltese would be admitted during the war; but after protracted negotiations an agreement was reached with the government of Malta whereby 260 Maltese—the average number of Maltese admitted to Australia during the last triennial period before the war—were to be admitted annually. This closed the incident temporarily. In January 1923 the arrival in Sydney of about 300 Italians, most of them destitute, brought the question of Italian immigration into public notice. They were returned to Italy, and an agreement was made with the Italian government by which the latter undertook to issue passports for Australia only to persons possessing capital or nominated by friends in the Commonwealth. Meanwhile the Maltese government had endeavoured to reopen negotiations on the subject of the quota restriction for Maltese, which was being used by certain anti-British elements in Malta as propaganda against British rule. The question was discussed at the Imperial conference of 1923, and an understanding was arrived at on the lines of the Italian agreement—with the additional provision that not more than 20 Maltese immigrants would be permitted to land from the same vessel or during the same month at any one port; illiterate Maltese would be admitted only by special permission obtained from the minister in charge, on the application of friends in Australia.

The tentative restriction of European immigration by agreement with the governments concerned was extended at the end of 1924 to cover intending immigrants from Greece, Jugo-Slavia, and Albania. Not more than 100 immigrants of each nationality will be admitted to the Commonwealth in any one month, and preference will be given to immigrants with a knowledge of English who possess capital or friends in Australia. Queensland in 1925 appointed a royal commission to investigate alien immigration as it affects that State.

See M. Willard's *History of the White Australia Policy* (1923) and P. Campbell's *Chinese Coolie Emigration to Countries within the British Empire* (1923).

Imperial Conferences. This title, properly speaking, belongs to the conference of 1911 and its successors; but it is conveniently applied (following the precedent set by Sir A. B. Keith) to its predecessors also.

The occasion of the first colonial conference (that of 1887) arose naturally out of the events of the time. In 1881 an intercolonial Australian convention had considered restrictive legislation to check the immigration of Asiatics; in 1882-3 alarm at the apparently aggressive policy of France and Germany in the Pacific islands had led to the attempt of Sir T. McIlwraith (q.v.) to annex New Guinea; this had been disavowed by the British government in spite of Australian unanimity in his support, and the disavowal prompted the holding of another convention in Sydney in 1883, out of which issued the Federal Council of Australasia. In 1885 the effects of a brief but agitated anticipation of war with Russia were felt almost as

vividly in Australia as in the mother country; the colonies realized that 'foreign complications' might affect them also, and turned their attention to the necessity for strengthening their own defences. Further, the affairs of Egypt had culminated in a dramatic military campaign in which Canadian and Australian troops had participated; and the patriotic action of the colonies in offering contingents of troops made some impression on the British public. Nor were the other British colonies entirely at rest; in Canada a local uprising had been suppressed by the militia after some fighting, and the aftermath of the South African war of 1881 was a bitter competition between Rhodes at the Cape and Kruger (who was seeking foreign support) in the Transvaal. At this juncture the Imperial Federation League took advantage of the Indian and Colonial Exhibition in London (July 1886) to hold a conference, largely attended by colonial visitors, at which commercial union and a joint system of defence were advocated. On 11 August the league urged on the then prime minister (Lord Salisbury) the summoning of an official conference, with a view to the creation of an Imperial council. On 25 November a despatch from the colonial secretary to 'Governors of Colonies under responsible government' suggested 'fuller consideration of matters of general interest,' such as military defence and the promotion of commercial and social relations by development of postal and telegraphic communications. 'What is known as Political Federation' was expressly deprecated. The constitutional position of the proposed conference was defined clearly. It was to be purely consultative; it was not material that the colonies should have equal or proportionate representation; but it should be sufficiently representative to include, in addition to the agent-general or other specially deputed representative of each government, any leading public man who might be at liberty to come to England, and might be especially qualified to take a useful part in the deliberations. Copies of the despatch were sent to governors of the crown colonies, but not to the viceroy of India.

At the opening meeting Great Britain was represented by the colonial secretary, the prime minister and seven other ministers; Canada by the lieutenant-governor of Ontario and Sandford Fleming; Newfoundland by its premier and Sir Ambrose Shea; New South Wales by Sir Patrick Jennings (an ex-premier), Robert Wisdom (ex-attorney-general), and Sir Saul Samuel (agent-general); Victoria by Alfred Deakin (chief secretary), James Lorimer (minister of defence), Sir Graham Berry (agent-general), and James Service (an ex-premier); Queensland by Sir Samuel Griffith (premier) and Sir James Garrick (agent-general); South Australia by John W. Downer (premier) and Sir Arthur Blyth (agent-general); Western Australia by John Forrest (commissioner of crown lands) and Septimus Burt; Tasmania by John S. Dodds (an ex-attorney-general) and Adye Douglas (agent-general); New Zealand by Sir F. Dillon Bell (agent-general) and the speaker of the legislative council; The Cape Colony by its attorney-general, its agent-general and Jan Hofmeyr; Natal by John Robinson. There were also present 33 representatives of 23 crown colonies, and 54 other British and colonial representatives. The attendance totalled 121 representatives of 35 governments; but subsequent business meetings were practically confined to the representatives (or some of them) of the self-governing colonies and of the British departments immediately concerned with the matter under discussion, whatever it might be. The session (20 meetings) lasted from 4 April to 9 May, and a complete official report was published in July. The matters discussed included naval defence, preferential trade, commercial treaties, sugar bounties, postal and telegraph communication, and the situation in the Pacific. Naval defence (as was intended by the British government) occupied the greater part of the session. As far as Australia was concerned, the discussion resulted in an agreement (discussed under NAVAL DEFENCE) under which the Australasian colonies hired a small squadron for local defence.

Arrangements were concluded for the annexation and administration of south-eastern New Guinea, and for maintaining the neutrality of the New Hebrides; and the principle of strengthening inter-communication by means of a cable across the Pacific was approved, though no definite procedure was arranged. The work of this conference was doubly handicapped. The representatives of the various colonies had no time to become acquainted with each other or to arrange a programme of business; and they were in any case so heterogeneous a mixture of ministers, ex-ministers, agents-general, and private citizens, that they could not speak with any semblance of authority on behalf of their colonies. They were, in fact, not unlike an assembly of feudal vassals, invited to confer with their overlord. The colonies took good care that this situation should never recur in London.

The Ottawa conference of 1894 developed from the informal resolutions in support of a Pacific cable that were passed in 1887. Although it was called by the Canadian government, not by the colonial office, and was intended specifically to discuss trade relations and telegraphic communication between Canada and Australia, all the self-governing colonies were represented except Western Australia and Natal, which were unable to send delegates, and Newfoundland, which was apparently not invited. This conference was much less informal than the first; at Ottawa only two delegates were neither ministers nor members of a legislature—and these two were Sandford Fleming, who had special knowledge of the cable question, and Lee Smith of New Zealand, which colony looked upon the conference as a commercial one. Lord Jersey represented the Imperial government. Three ministers and Sandford Fleming represented Canada, one minister New South Wales. South Australia sent its agent-general. The Cape delegation again included Jan Hofmeyr, but its three delegates, like those of Victoria (3), Queensland (2), Tasmania (1), and New Zealand (1), held no ministerial office.

With regard to trade relations and preferential trade this conference recommended 'that provision should be made by Imperial legislation enabling the dependencies of the Empire to enter into agreements of commercial reciprocity, including power of making differential tariffs with Great Britain or with one another,' and recorded 'its belief in the advisability of a customs arrangement between Great Britain and her colonies by which trade within the Empire may be placed on a more favourable footing than that which is carried on with foreign countries.' As for the Pacific cable, it was resolved that 'immediate steps should be taken to provide telegraphic communication by cable, free from foreign control, between the Dominion of

Canada and Australia,' and that the Imperial government should be requested to undertake as soon as possible the thorough survey of the route, the expense to be borne in equal proportions by Great Britain, Canada, and the Australasian colonies.

An 'All Red' mail service was also discussed, as were the law of copyright—shelved because Lord Jersey mentioned that a committee on copyright was sitting in England—and the harmonizing of the bankruptcy laws of the various States. Like the first, this conference (owing to its composition) lacked authority. After 12 months' consideration of its resolutions, the British government announced that Imperial reciprocity would provoke foreign retaliations, and bring serious difficulties to the colonies as well as disaster to Britain. Intercolonial trade preference was condemned; in fact, the colonies were told, politely and emphatically, that Mamma knew best.

The conference of 1897 resembled that of 1887 in so far as it was incidental to an Imperial festival and a Royal Jubilee; but, both in form and in conclusions reached, it marked a decided stage in the development of the Imperial conference as an institution.

For the first time, albeit by accident, the colonial membership was confined to premiers of responsible governments; for the purpose of the Jubilee ceremonial premiers alone had been invited and thus were alone available for the conference. On this occasion, therefore, for the first time the conference assumed the shape, since stereotyped, of an assembly of autonomous governments, collectively the rulers of the whole Empire. Joseph Chamberlain, then colonial secretary, presided; the premiers present were Sir Wilfrid Laurier (Canada), G. H. Reid (New South Wales), Sir George Turner (Victoria), Sir Hugh M. Nelson (Queensland), C. C. Kingston (South Australia), Sir Edward N. C. Braddon (Tasmania), Sir John Forrest (Western Australia), R. J. Seddon (New Zealand), Sir J. Gordon Sprigg (The Cape Colony), Harry Escombe (Natal), and Sir William V. Whiteway (Newfoundland).

Chamberlain in his inaugural address proposed the formation of an Imperial council. He received no support from the colonial premiers; but from this time forward the alternative ideas of (*a*) developing the conference itself into the nucleus of an Imperial organization, (*b*) converting it into an advisory council, if not superseding it altogether, were frequently discussed by publicists and the press. The matters dealt with during the conference included colonial defence, preferential trade, Imperial penny postage, the Pacific cable, and colonial relations with foreign countries. It was agreed to prolong the Australasian naval agreement of 1887, and the Cape Colony came forward with the offer of a naval subsidy. With regard to trade, the premiers recommended the denunciation of treaties that might hamper commercial relations between Great Britain and her colonies, and undertook to consider whether preference could be given by the colonies to products of the United Kingdom. The future administration of British New Guinea, the Solomon Islands, and the New Hebrides was discussed privately with the premiers concerned. It was further agreed that periodical conferences would be of great value, and that colonies united geographically should where practicable form a federal union. Before the next conference met, Australia had demonstrated her acceptance of this last resolution, and the colonial units of the conference were thus reduced from eleven to six—a far more workable committee of the Empire.

Like two of its predecessors, the conference of 1902 was incidental to an Imperial festival —on this occasion the coronation of King Edward. The subjects indicated by the British government were the political and commercial relations of the Empire and its naval and military defence, but the colonial governments were invited to submit additional subjects for discussion. The representation of the self-governing colonies was not restricted to their premiers; the Australian minister of defence and four Canadian ministers were present, but took part in the discussions only when their special subjects were touched on. Britain sent Joseph Chamberlain, still secretary for the colonies, and the ministers concerned with naval and military defence. New Zealand, The Cape Colony, Natal and Newfoundland were represented by their premiers. There were ten sessions, lasting through June and July.

The chief subjects under discussion were naval defence, preferential trade, and the continuity of the conference system; in regard to the last it was arranged that conferences should be held every fourth year. Preferential trade was approved as a colonial measure—i.e. the colonies agreed to give preferential treatment to British goods and products of countries within the Empire. As for naval defence, the Australasian agreement was altered in a way that suited neither side. The auxiliary squadron disappeared; the colonial contributions became a mere subsidy—which was very displeasing to Australian feeling, and a year later wrecked the Barton ministry in the Commonwealth; and the admiralty (which had hoped that the Imperial spirit shown in the South African war would have elicited lavish contributions from the colonies) was disappointed both with the smallness of the subsidies and with the concurrent condition that Australasian sailors should be trained alongside British sailors at higher rates of pay. Minor and vaguer resolutions approved of mail-services across Canada, mutual protection of patents throughout the Empire, cheap postage, and the adoption of the metric system. In his opening speech Chamberlain advocated the formation of 'a real council of Empire, to which all questions of Imperial interest might be referred,' but the suggestion fell flat. It was, however, taken up afterwards by enthusiasts in England, who in 1905 persuaded Alfred Lyttelton (then colonial secretary) to suggest to the self-governing colonies the formation of an Imperial advisory council; but Canada and Newfoundland objected at once, and no more was heard of the suggestion officially.

The trend of British politics now brought preferential trade into the centre of Imperial politics. In the conference of 1907, therefore, it became the chief subject of discussion. This conference had been postponed for a year by the British government, but proved by far the most important held up to that date. Two subsidiary conferences, one convened by the board of trade in advance of the main conference to discuss Imperial navigation laws, the other by the board of education afterwards to discuss that subject, added to its prestige. Australia through its prime minister Alfred Deakin, took the lead in suggesting subjects; her list included, besides preferential trade, the desirability of establishing an Imperial secretariat, new proposals for the naval defence of the Pacific, and

the reorganization of the colonial office so as to give its officials fuller personal knowledge of the colonies with which they had to deal.

The British prime minister, Sir Henry Campbell Bannerman, opened the conference, but at later meetings the colonial secretary presided. Ten other members of the British cabinet attended when subjects within their purview were being discussed. From Canada Sir Wilfrid Laurier brought his ministers of defence and marine, the former being Sir F. Borden. Deakin was accompanied by Sir W. Lyne. Dr. Jameson from the Cape Colony brought his minister for works; New Zealand, Natal and Newfoundland were represented by their prime ministers only. The assistant ministers, of course, took part only in debates on their own subjects. In this conference Deakin asked for full publicity, but Sir W. Laurier suggested that (as in 1902) only the bare resolutions should be published at once, and a full report issued at the end of the conference. Lord Elgin demanded privacy. Eventually a compromise was agreed on—that a summary should be prepared and issued daily by official secretaries (each member being given a chance of revising his remarks), and a full report issued at the end of the conference; but the plan was not well carried out.

The session opened on 15 April and closed on 14 May. Of the 15 days spent in actual conference five were occupied with preference and five with constitutional and defence discussions. As regards preferential trade, the conference (with the exception of the British government) confirmed the resolutions of 1902; the British government finally and absolutely rejected Imperial reciprocity in any shape. On the constitutional point it was resolved that a conference—to be called the 'Imperial' Conference—be held every four years, all prime ministers and the British colonial secretary being *ex officio* members; governments might appoint additional ministers, but (except by permission) not more than two representatives from one government should join in each discussion, and each government should have but one vote. A permanent secretarial staff should be appointed. Provision was also made for subsidiary conferences. Respecting defence it was resolved that the colonies be authorized to ask the committee of Imperial defence, through the secretary of state, for advice on any local questions; a desire was also expressed for an Imperial general staff, to study military science and disseminate to the various governments military information and intelligence.

Many other subjects—including intra-Empire migration, penny postage, the 'all red' mail route, double income tax, copyright, and the New Hebrides convention—were discussed and vague resolutions passed thereanent; it was decided to hold a subsidiary conference on naturalization; and Deakin urged the British government to prepare a statement showing colonial obligations in respect of British treaties. But one of the most important of the Australian suggestions—that concerned with an Imperial secretariat—was misapprehended and mishandled until its adoption produced more irritation than it was worth. The original suggestion was to set up in London a secretariat consisting of expert officials from all the self-governing colonies, who would be in close touch both with their own and with the Imperial government, and should be consulted as to facts whenever a question of Imperial (as opposed to purely British) importance came up for settlement. These officials were not to be politicians or to have the power of committing their government to any decision; they were there for information, to enable both sides to avoid mistakes about fact. But between the jealousies of the colonial office—which objected to the intrusion of any outside body into affairs it considered its own—and the praiseworthy but impracticable aspirations of Imperial enthusiasts who wanted to set up a ministerial council in London, capable of committing colonial governments to political decisions (the old Imperial council under a new name), Deakin's secretariat came to nothing, and the colonial office was allowed to create a secretariat of its own, with no special personal knowledge of colonial affairs, that became merely a mechanism for maintaining connection between one conference and the next.

In 1909 a very important subsidiary conference dealt with questions of Imperial defence. An agitation for the increase of the British navy, in view of the growing naval power of other nations, had led to several unco-ordinate offers from colonies to provide battleships for Imperial use (see NAVAL DEFENCE); the situation was an embarrassing one for the British government, partly because it had no particular desire to admit colonial governments to a share in its naval policy, partly because it was evident that the offers were not a spontaneous expression of each community's unanimous good will. A conference seemed the best way out of the imbroglio; the result of it was to disclose great differences of opinion among the dominions (as the self-governing colonies were now called). Canada proposed to establish a small auxiliary squadron of light cruisers and destroyers, New Zealand maintained her prime minister's offer of a battleship (to be added to the British navy and placed on the China station), and Australia adopted wholeheartedly a suggestion made rather grudgingly by the admiralty that she should provide and maintain one 'unit' of a Pacific fleet, the other two units being provided by the British government as the China and East Indies squadrons. South Africa, which was still unfederated, postponed its decision until the Union should be accomplished. The military side of the conference decided that dominion forces, while remaining wholly under the control of their own government, should be as far as possible standardized in formations, training and equipment on British army patterns. It was through its representatives at this conference that the Australian government made its first protest against the failure of Great Britain to consult the Commonwealth with regard to the Declaration of London—an important international agreement. Another subsidiary conference in 1910 discussed Imperial copyright.

The conference of 1911 was a marked advance on all its predecessors. The British government had at last begun to realize that the self-governing colonies stood apart from the bulk of colonies administered by the colonial office, and must be treated as semi-independent entities within the Empire; and the admission of the change was marked by calling the conference for the first time an 'Imperial' conference and by placing it formally under the presidency of the British prime minister as the conference of 1907 had desired. Held after the agreed-on four-year interval, it fortunately coincided with the coronation of George V, and its prestige was enhanced by the accompanying

ceremonials and the presence in London of distinguished visitors from all the world over. Britain was represented by the prime minister (Herbert Asquith) and the secretary for the colonies (Lewis Harcourt), eight other cabinet ministers attending when the discussions entered their sphere. Canada sent its prime minister (Sir Wilfrid Laurier) with his ministers of defence and marine. From Australia came the prime minister (Andrew Fisher) with the ministers for defence and external affairs. Sir J. Ward brought his attorney-general from New Zealand; General Botha his ministers of education and works from South Africa; Sir E. P. Morris his colonial secretary from Newfoundland. The proceedings lasted from 23 May to 20 June, during which time eleven formal meetings were held, besides many secret meetings that must be discussed separately. The conference was further notable because three of the dominions—Australia, New Zealand, and South Africa (which by this time had become a Union)—practically took charge of the business paper. The Australian government put forward (among others) resolutions concerned with naturalization, migration within the Empire, trans-Atlantic cable communications, the Declaration of London, the status of dominion navies, and the general co-operation of British and dominion defence forces. New Zealand was also much interested in cable and mail communications; but her chief resolutions dealt with the establishment of an 'Imperial Council of State,' the substitution of high commissioners for governors-general as the sole channel of communication between the British and the dominion governments, and the complete reconstruction of the colonial office. South Africa wanted British relations with the dominions taken wholly out of the hands of the colonial office and placed immediately under the British prime minister; she was also interested in naturalization, and had a complicated scheme (which came to nothing) for balancing her contribution to naval defence against her preferential treatment of British goods. So, indeed, did most of the New Zealand proposals, which had obviously not been thought out; the Council of State was condemned all round, and the reorganization of the colonial office was shown to be unnecessary. The Australian objections to the Declaration of London produced a remarkable situation. The Australian prime minister began by declaring that the dominions ought to be consulted before the Imperial authorities bound them to obey international agreements; this was amicably settled by a British offer to consult the dominions in future 'when framing the instructions to be given to British delegates' at the Hague and to other international conferences. But the British ministry took advantage of this amicable spirit to attempt to obtain from the conference a resolution explicitly approving the Declaration itself. To this the Australian delegates strenuously objected. Extreme pressure was brought to bear on them, the British ministers desiring particularly to secure colonial approval of their diplomacy, to be used as an argument in the struggle which they foresaw over the Declaration in the British parliament. In the end the Australians yielded so far as not to vote against the resolution; they deliberately abstained from voting at all, and their attitude was fully justified when in the early months of the war it was attempted to put the Declaration into practice. Some agreement was arrived at in connection with questions of naturalization, but in respect of most of the other questions raised the results of discussion were either vague or non-apparent.

But the distinguishing event of the 1911 conference was technically altogether outside it. The discussion of naval and military affairs was formally relegated to the committee of Imperial defence, of which the colonial ministers were made members; and it thus became possible to explain to them fully and clearly both the secrets of British foreign policy and the British view of the international situation, on which all sound defence policy must be based. This deliberate admission of colonial ministers into the *arcana imperii* was welcomed by them as acknowledging irrevocably the right of the dominions to take a share in the direction of Imperial policy, and foreshadowed the Imperial war cabinet that was developed in the stress of fighting six years later. The immediate effect of the disclosures on practical defence measures was not great, though of course it led to increased zeal in standardizing all Imperial defence forces. The two dominion navies, also (if the term may be applied to such small squadrons), were brought into intimate relations with the British navy; they were allotted 'stations' for the defence of which they became responsible, they were given permission to fly the white ensign, and the personnel was made interchangeable with that of the British navy.

Although Imperial foreign policy was for the first time reviewed in detail at the conference of 1911, no adequate provision was made for keeping Dominion premiers in touch with foreign affairs during the intervals between conferences. The British government merely undertook to consult them on any treaties under consideration 'as far as possible and when time and opportunity and the subject-matter permit.' This was obviously unsatisfactory, and proposals were made for the appointment of resident ministers in London who could act as liaison officers. In 1912 the colonial office invited the Dominions to appoint such ministers; but the proposal was received coldly except in Canada (where Sir R. Borden was in office), and nothing further was done towards Imperial co-operation until the war had run two years of its course. The conference due in 1915 had been, of course, postponed; yet there was a general and insistent demand from the Dominions for some share in the responsibility of directing a struggle which concerned them so nearly.

The change, when initiated, was of great moment. One of the difficulties in the way of closer co-operation had been the fact that until the end of 1916 the conduct of the war was in the hands of the British cabinet, which was also responsible for the purely domestic policy of Great Britain: in such a cabinet the Dominions could claim no representation. But, when Lloyd George at the end of 1916 organized a war cabinet, the way was open for Dominion premiers to join it. An Imperial war conference was thereupon summoned, and two Imperial bodies were organized.

In March 1917 the first Imperial war cabinet was formed by adding the Dominion prime ministers to the British war cabinet—on which W. M. Hughes (q.v.) thus became the Australian representative; this body deliberated upon the larger issues connected with the war and its conduct, and exercised definite executive functions. In it Dominion members were on an absolute equality with the British, having full powers of question, examination, and initiation hitherto reserved to the chief ministers of the

British government. Each Dominion had its full share in determining military and foreign policy, especially in connection with the peace. It was resolved that the Imperial war cabinet should meet annually during the prosecution of the war; in fact, it met again in June-July of 1918, and then immediately after the armistice, remaining in continuous session (as the British Empire Delegation) until peace was signed.

The second Imperial body which met in 1917 was the Imperial war conference, a much larger and less responsible body without executive power. Presided over by the colonial secretary, it discussed war problems of minor importance, and Imperial problems apart from the war. The most significant debate of 1917 was that on the future constitution of the Empire, culminating in a 'constitutional resolution' that the readjustment of the constitutional relations of the component parts of the Empire, being too important and intricate a subject to be dealt with during the war, should form the subject of a special Imperial conference to be summoned as soon as possible after the cessation of hostilities. Any such readjustment, while thoroughly preserving all existing powers of self-government and complete control of domestic affairs, must be based upon a full recognition of the Dominions as autonomous nations of an Imperial Commonwealth, and of India as an important portion of the same; must recognize the right of the Dominions and India to an adequate voice in foreign policy and in foreign relations; and must provide effective arrangements for continuous consultation in all important matters of common Imperial concern and for any consequent concerted action. After debate in the conference of 1918 the war cabinet resolved that Dominion prime ministers should have the right (*a*) of direct communication with the prime minister of the United Kingdom, and vice versa, in reference to questions of cabinet importance, and (*b*) of nominating a cabinet minister to represent them at meetings of the war cabinet between plenary sessions. But the peace negotiations brought the prime ministers back to Europe before any action could be taken on this second resolution.

The Empire was represented on the supreme war council of the Allies by the Imperial (not the British) war cabinet, and thus any Dominion prime minister had the technical right to attend meetings of the council quite apart from his position as the representative of a small nation. The self-governing units of the Empire were now politically organized as a group of autonomous states, united on a basis of complete constitutional equality under a common Crown. This changed status was very evident in the conference of September 1921—'the conference of Prime Ministers of the United Kingdom, the Dominions and India,' the colonial secretary being present on behalf of the crown colonies and protectorates. This unwieldy designation was adopted in preference to 'Imperial cabinet' (which to the Dominions signified a central executive removed from popular control) or 'Imperial conference,' a term identified with the pre-war conferences in which Dominion equality was not fully recognized. The conference of 1921 was not merely informed about foreign affairs; it was admitted to be the body responsible for formulating Imperial policy. Particular attention was paid to the situation in the Pacific, and action was taken to secure an exchange of views at an early date with the United States and Japan with regard to the limitation of naval armaments—though nothing came of this until the United States called a conference at Washington. Consideration was also given to questions of Empire settlement, the position of British Indians domiciled in the Dominions, improved transportation facilities, etc. The special conference on constitutional relations was not called; the subject was discussed, but it was considered better, under existing conditions, to postpone any attempt to define the existing relationship by a political formula.

The latest Imperial conference, which met in October 1923, was similar in character to that of 1921. Its importance was enhanced by the holding of an 'Imperial Economic Conference' at the same time; this considered an extension of Imperial preference to secure for Dominion products special treatment on the English market, the related question of oversea settlement, proposals for British financial assistance of developmental works within the Empire, the improvement of mutual trade and Imperial communications, co-operation for technical research and information, etc. The political conference concerned itself primarily with foreign affairs. An important resolution concerned the negotiation, signature, and ratification of treaties. Its effect was that bilateral treaties imposing obligations on one part of the Empire only should be negotiated and signed by a representative of the government of that part; where a bilateral treaty imposed obligations on more than one part of the Empire the treaty should be negotiated and signed by one or more plenipotentiaries on behalf of all the governments concerned; in the case of treaties negotiated at international conferences, the existing practice of signature by plenipotentiaries on behalf of all the governments of the Empire represented at the conference should be continued. The conference agreed to the British proposal that a special service squadron (including two capital ships) should visit the British possessions in the Pacific, proceeding via Suez and returning via Panama. The conference also noted the deep interest taken by Australia, New Zealand, and India in the development of a naval base at Singapore, which would ensure the naval mobility necessary for the security of Imperial territories and trade in the East. Questions relating to the position of Indians resident in various parts of the Empire, to protected and mandated territories, and to the law of British nationality were also considered.

See A. B. Keith's *Responsible Government in the Dominions* (1912), *Imperial Unity and the Dominions* (1916), and *War Government of the British Dominions* (1921); and Richard Jebb's *The Imperial Conference* (1911).

Indian. This adjective is used in conjunction with a few European plant-names to denote certain Asiatic and Australian plants supposedly resembling their namesakes. For the Indian almond see TERMINALIA; Indian coral-tree, ERYTHRINA; Indian mulberry, MORINDA.

Indigofera, a large genus of the family Leguminosae, consisting of herbs or shrubs, chiefly dispersed in warm regions; several of the species indigenous to Australia extend to India. The flowers are red or purple, in spikes; pod elongated, cylindrical or angular, with cellular partitions between the seeds. *I. tinctoria,* a native of northern Queensland, produces the indigo of commerce. *I. enneaphylla* is regarded in India as a diuretic and febrifuge.

Industrial Disturbances. See STRIKES.

Industrial Law in Australia consists mainly of three elements: (*a*) the *Inherited Element*, that part of the existing law which was brought to Australia by the first settlers; (*b*) *Remedial or Ameliorative Statute Law*, a heterogeneous body of statute law, either developed locally or derived from the remedial legislation of the United Kingdom which followed in the wake of the industrial revolution in England, the Chartist movement, and the reform bill of 1832; (*c*) the *Law of Industrial Arbitration*, a new and experimental branch of law in which New Zealand and Australia have been pioneers —though one source of it is found in the socialism of 'Young Oxford' as exemplified in the writings of Arthur Hugh Clough.

The *inherited* element consists of so much of the common law as relates to contracts of employment and the parties to them, with some statutory modification. When the doctrine of freedom of contract was at its height (about 1860-1885 in the legislative history of Australia), this common law element was of somewhat greater importance than it is to-day. But it is still vastly important; for, though statutes and industrial awards regulate certain conditions of employment, parties still enter into and dissolve their own contracts, and the accepted legal theory is that the relationship of employer and employee is governed by contract made between the parties, the terms of which are mutually agreed upon—subject, however, to express legislation or awards directly in point. Moreover, for parties not affected by legislative interference the fullest freedom to contract remains, and parties within the scope of industrial arbitration may make agreements not contravening appropriate awards or other legislation. In fields untouched by industrial legislation the common law governs; e.g. it is not necessary to prohibit slavery by statute, because the common law will not allow imprisonment by a master of a servant, nor will equity protect a contract savouring of slavery. Again, contracts in restraint of trade are illegal at common law upon grounds of public policy, and this extends to contracts restrictive of a man's right to work at his calling; for the state has an interest in the producing power of its citizens, and a man is not allowed to contract himself out of the right to maintain himself at his proper calling in his own country. So well accepted is this ground of illegality in common law that the Australian law courts (as well as English and American courts, wherever the common law prevails), have, by a series of precedents and without legislative interference, defined with great precision the limits within which restrictive contracts will be enforced, and the appropriate remedies, if any. It would be a simple matter to multiply instances of the operation of common law in this field.

The inherited statutory modifications of the common law are noteworthy. From the time of the statutes of labourers (passed after the 'black death,' cf. 25 Edw. III Stat. 1) there has always been a certain amount of labour legislation in England. See Jenks's *History of Politics* (xiii, 137) and the introduction to Smith's *Law of Masters and Servants* (xxxviii sqq.). In 1828 the English law then in force, so far as it was reasonably adapted to the circumstances of the colony and capable of being enforced here, was expressly applied to New South Wales by 9 Geo. IV c. 83. Among the statutes so applied was the Masters and Servants Act, which was amended and revised locally from time to time. The effective remains of this and all early colonial legislation on the subject is found, for New South Wales, in the Masters and Servants Act 59 of 1902, a consolidating act. Many of the provisions of this act are counterparts of the English statute 4 Geo. IV c. 38 (A.D. 1823), since consolidated in England in the Employer and Workman Act of 1875. Its main features are the provision of summary remedies in the magistrates' courts, —for masters against servants who break their agreements, conduct themselves fraudulently in the obtaining of contracts of employment or the breach thereof, or wilfully spoil or destroy—and for servants against masters and masters' agents who fail or delay in paying wages or improperly withhold servants' property, etc. The language and remedies of the act are somewhat old-fashioned and drastic, but its benefits are considerable, and its remedies in constant use. Similar law obtains in other States, but not always under the same name; in Queensland it is the same, but in Victoria, owing to more recent revision and consolidation with other statutes, its form is more modern, and it forms a part of the Employer and Employees Act No. 2646 of 1915—an act that embraces other matters, such as employers' liability and contractors' debts, which in some States are the subject of separate statutes.

The *remedial or ameliorative statute law* is found in the legislation of the various States; except in respect of seamen, there is none of it in the Commonwealth statutes. Nearly all the beneficial legislation of the United Kingdom which was passed from 1830 onwards, to remedy the state of affairs which developed in factories, coal-mines and the like in England in the first quarter of the last century, has been adopted by some or all of the local State legislatures: e.g. the Truck Act, the Coal Mines Regulation Act, and the Factories and Shops Act. Of this class, too, are the Mines Inspection Act, Miners' Accident Relief Act (now superseded), Children's Protection Act, Apprentices Act, Attachments of Wages Limitation Act, Coal Lumpers' Baskets Act, Scaffolding and Lifts Act, Early Closing, Saturday Half-holiday, Contractors' Debts, and Shearers' Accommodation acts. All the foregoing are titles of New South Wales statutes. In Queensland the Shearers' Accommodation Act becomes the Shearers' and Sugar Workers' Accommodation Act, and the Contractors' Debts Act (not known in England) becomes the Workmen and Contractors' Lien Act; in Victoria it is consolidated in the Employer and Employees Act (mentioned above), and there are substantial differences of matter as well as of title. It is thus impossible to describe this multiform legislation, even in broad detail, for any one State of the Commonwealth, much less for all. The titles of the acts indicate their scope. All are not found in every State. Some are designed for purely Australian habits and conditions and originated here. Upon the whole it may be said that the enactment of the greater part of this legislation was due to the rise of the Labour party in Australian politics. Some of the English laws which are reproduced in this list did not find their way on to the Australian statute-books till long after they were first enacted: the Truck Act (New South Wales) No. 55 of 1900, which prohibits the payment of wages in goods and makes them payable in money only, was enacted first in Australia in that year, though based on the English statute of the same name of 1831 (1 and 2

Will. IV, 37); and this statute, not altogether suited to sparsely settled countries, has not been adopted in all States.

With this group of statutes may be classed those dealing with workmen's compensation. The Employers' Liability Act, passed in England in 1880, was enacted in almost identical language in all the States of Australia. It is now repealed, or in effect superseded, in Australia as in England by the Workmen's Compensation Act, which, as enacted in the various States, follows closely its English model and proceeds upon the novel principles of that act. Questions of negligence or contributory negligence on the part of employer or employee are passed over as irrelevant (except under the head of serious and wilful misconduct), and rights to compensation are provided for all cases of personal injury caused to a workman by accident arising out of and in the course of his employment. The latest New South Wales statute (act 71 of 1916 as amended by No. 45 of 1920) is the most liberal in its compensations. It applies to practically all employees except those whose remuneration exceeds £525 per annum. For Victoria see act No. 2750 of 1915 as amended by No. 3217 of 1922, which embraces workers on wages and persons employed otherwise than in manual labour, if they are not getting more than £350 per annum.

Each State has its own system of *industrial arbitration*, all differing from that of New Zealand. All are directed against sweating, and are in general attempts to improve the condition of workers and to provide peaceful methods of settling or preventing industrial disputes. In addition there is the Commonwealth system. It is proposed here to offer some explanation of the Commonwealth system, and of those of the two most populous States, New South Wales and Victoria; the systems of other States are merely indicated. Development has been great and continuous. Under no government has the progress of the arbitration system been really checked; yet strikes have not been avoided. Industrial arbitration continues to find a general acceptance by the public, and this is no doubt due to the fact that it deals with much besides strikes.

With regard to the avoidance of strikes not many minds will agree as to what the lessons of experience are, but it is tolerably clear (*a*) that it is inexpedient to legislate upon the footing that striking is in its nature an offence to be dealt with by ordinary criminal law, (*b*) that punishment for industrial offences should be developed as far as possible from within the system, e.g., in deprivation of the benefits of the system, and (*c*) that fuller education of the public is needed regarding civic rights and duties, in order to promote resistance to anti-social action.

The Commonwealth of Australia has power by its parliament to make laws for the peace, order and good government of the Commonwealth with respect (among other things) to 'Conciliation and arbitration for the prevention and settlement of industrial disputes extending beyond the limits of any one State' (Constitution Act, sec. 51 p. xxxv). In the exercise of this power the Commonwealth Conciliation and Arbitration Acts 1904-1921 were enacted. During the 17 years mentioned in the title nine amending acts have been added to the original and principal statute. The chief expressed objects of the act are to prevent lockouts and strikes; to create a Commonwealth court of conciliation and arbitration, endowed with jurisdiction for the prevention and settlement of industrial disputes; to provide for the exercise of the jurisdiction of the court by conciliation and, in default of agreement, by equitable award; to enable States to refer industrial disputes to the court, and permit the working of the court and the State industrial authorities in aid of each other; to encourage the organization of industrial bodies and the submission by them of their industrial disputes to the court; and to provide for the making and enforcement of industrial agreements between employer and employee. In practice, the court has in the main been occupied in the making of industrial awards, or in obtaining industrial agreements with the aid of its power to summon parties to a compulsory conference.

The high court has often been appealed to to decide whether a course of action or an award proposed by the Commonwealth court of conciliation and arbitration is in accordance with the principal act and the constitution, and also as to the validity of sections of the act. In particular, the high court has held that a provision purporting to empower the Commonwealth arbitration court to declare its awards to be common rules in the industries to which they relate is invalid; and this condition, though improved by an amending act, has somewhat restricted the development of that court, whose awards are in this respect inferior to those of State courts. Wherever an employment is governed by a Commonwealth award and a State award, both awards must be obeyed if possible. Awards which prescribe differing minimum rates of wage for identical work can both be observed by paying the higher rate (*Whybrow's Case (No. 1) 10 C.L.R. p. 266*).

The Commonwealth court has dealt with many industries of an inter-State character, e.g. those of seamen, ships' officers, engineers and stewards, wharf-labourers (where, though the individual labourers are local, they work for employers engaged in every State and whose ships move from State to State), and shearers, who move from State to State though their employers are in the main localized. The inter-State character of these industries is obvious; but after the Builders' Labourers' case it became plain that any industry can be treated as having a dispute extending beyond the limits of one State by the extension of the union organization into the federal sphere and the device of making similar or identical demands from employers in more than one State. In such a case the court can determine that a dispute within its jurisdiction has in fact arisen, and the high court will not interfere by writ of prohibition (*The Builders' Labourers' Case 18 C.L.R. 224*); nor will the privy council, on appeal from the high court, go into the question—since the Constitution forbids appeals to the privy council upon questions, howsoever arising, as to the limits *inter se* of the constitutional powers of the Commonwealth and those of any State or States. The high court may, of course, give a certificate allowing such an appeal, but did not in the case quoted. And the later case of the Amalgamated Engineers *v.* Adelaide S.S. Coy. shows that certain instrumentalities of State governments (e.g. railways, water boards, and trusts and corporations with similar functions) are subject to the federal industrial power. Thus Commonwealth awards can be applied in any industry, but cannot be made rules common to the whole industry. Still, if the employers are limited and definite, they can all be joined as respondents, and, if all

the employees were in the union affected, the result would be equivalent to regulation by common rule. Since these conditions rarely concur, the Commonwealth awards are imperfect in their application, while the system is in other respects less adaptable than those of the more important States. But the number and importance of the industries dealt with in the Commonwealth court is very great. Attempts made by the State governments from time to time to restrict these by some form of compromise or arrangement with the federal government have not as yet borne fruit. The high court in its decisions on appeal has, latterly, been keenly appreciative of the sense of the legislature in endowing this court with the completest power the constitution will allow. Recent attempts to curb the authority of the Commonwealth court of conciliation and arbitration upon the ground of *ultra vires* have been unsuccessful.

This beneficent interpretation, and the wide language of the statutes on which the court is founded, give it far-reaching power and cause much awkward overlapping of federal and State awards. In addition the Commonwealth court has gone very far in its reading of the word 'industry;' this is essential to the extensive jurisdiction which it has attained. Not only are many State services held to be industries and capable of industrial disputes 'extending beyond the limits of any one State' *ut supra*, but all grades of municipal employees, musicians, journalists, bank officials and those in the employ of insurance and trustee companies are held to be employees in industry. Further, no limit has been set by the legislature to the amount of wages or salaries which the court may fix in its awards; in many cases salaries of £700 per annum and more have been made the subject of an industrial award.

New South Wales.—Industrial arbitration was first introduced into New South Wales by the Industrial Arbitration Act of 1901 (Wise's act). This act created a court, consisting of a judge and assessors, which made the necessary industrial awards. An award was made between parties to a dispute; when this was done, a fresh substantive application could be made to the court for an order making such an award a 'common rule' in the industry.

This court was so much used as to become congested. The duration of the act, however, since it was admittedly an experiment, was limited to seven years, and in 1908 the Industrial Disputes Act (Wade's act) took its place. Under this act the court worked with a subject set of industrial boards, popularly known as 'wages boards'—the term being borrowed from the wages boards system of Victoria, then already in force (see below). The boards were created from time to time as required, and made industrial awards upon the application of bodies of employees, or employers of at least 20 men. All awards were subject to appeal to the court. The boards were miniature courts, consisting of a neutral chairman—usually a lawyer—and laymen assessors, one or two a side, representing employers and employees in the industry; they were subject to the control of the court in their creation, the marking out of their jurisdictions, dissolution and otherwise. Awards when made were common rules for the industry or portion of the industry to which they were directed, usually for a period of three years. This statute removed some defects that had appeared in the Wise act, and avoided the congestion of the court by the creation of boards as required, to each of which a single substantial business was entrusted. The act was several times amended. An amendment which had great notoriety, and a substantial effect on the future of arbitration, was made by the Industrial Disputes (Amendment) Act (No. 26 of 1909), which soon became famous in State politics as the 'leg-iron' act. This act was in itself an honest attempt to cure one of the weaknesses of industrial arbitration by making more effective the law against lockouts and strikes; but excess of zeal on the part of some policemen, who had in their charge persons under arrest for the offence of instigating a strike, led them to put leg-irons on the prisoners, and the incident gave rise to a political cry designed to assist in winning the next election for the Labour party.

In 1912 the Wade act was repealed, and replaced by the Industrial Arbitration Act of 1912 (Beeby's act), which preserved industrial boards, but arranged them in groups each under a single chairman; the building trades formed a single group, and the iron trades, leather trades, and manufacturing and transport industries became separate groups also. In all there were about 24 groups of boards, and more than 200 awards in force at a given time. The Beeby act further provided merely a monetary fine for the offence of instigating persons to strike. But awards can be rescinded, boards dissolved, and unions de-registered if not worthy of the advantages of industrial arbitration. Beeby's act also made elaborate provision for conciliation committees, which, however, have not yet been much used. Nevertheless a great deal of conciliation went on and continues, (*a*) within the board system, resulting in awards by consent of parties, and (*b*) outside it, by means of industrial agreements, which when registered are recognized by both earlier and later statutes as operative with the force of awards between the parties making them. It may be doubted whether the regulations under which the boards were instituted sufficiently encouraged this; indeed, their procedure, which resembled that of law-courts, was thought by many to be productive of the opposite result.

All this time the size and expense of the system had been steadily growing. In 1916 an amending act (No. 81 of 1916) made provision for more judges, in the hope that the hearing of cases and making of awards by single judges, doing the work of boards, would prove a quicker and less expensive system. Soon the work of industrial boards as then constituted was completed, and all new work was taken over by the judges, who may sit with assessors (but this has not been usual) or may, instead of dealing with applications for awards, refer any application to a board. Hence boards were kept in existence, but under the recent policy are inactive. Applications are in theory made to the boards, but really to the court. So far three judges have succeeded in doing all the necessary work.

A notable development of the system was made in 1916 by the repeal of the schedules to the principal act which had described and limited the persons for whom the act was intended. The sphere of industrial arbitration was at once widened to embrace employees for hire or reward in any craft, occupation or calling, and their employers. This is subject to very few exceptions. The Crown is included as an employer; but by further amendment in 1922 employees

under the Public Service Act of 1902 have been, like the police, excluded; and managers generally are outside its scope. Further extensive amendments were made in 1918—No. 16 of 1918—(*a*) by way of improvement of the existing legislation, perfecting the powers of judges, (*b*) adding a part (VIIa) dealing with the management, rules, funds and membership of trades unions—and three entirely new parts (IX, X, XI), each of which represents a substantial addition to the system. Of these, part IX provides for a board of trade, to which the most extensive powers of enquiry and recommendation in all kinds of socio-economic matters are given, as well as the power (and the duty) to declare the 'living' wage to be paid to adult male and adult female employees in the State, or in any defined area. Such declarations are rapidly translated into awards and become the basis of future awards or industrial agreements. This board has also power to control and direct the conditions in all respects of apprenticeship in any industry. Indeed, it could become a very great power in the State, but recent policy has somewhat limited its activity. Part X deals with the organization of the labour market by state labour exchanges, and the regulation of private employment agencies. Part XI provides for the initiation of a scheme of insurance against unemployment.

A typical industrial award contains from ten to twenty clauses, and is framed and interpreted in much the same way as an act of parliament, but the industrial court (which is of final authority in the interpretation of all awards) has power of its own motion at any time to vary an award. The usual clauses of an award prescribe (1) the area where the award shall apply; (2) the usual hours of work, by the day or week, as the case may require; (3) the minimum wage, by the hour, day or week (or for piecework)—this clause may be simple if it deals with employees all of one class or grade, or complicated to provide for seniors, juniors, apprentices, youths, female labour or a great variety and classification of workers in the same industry—(4) overtime rates of pay; (5) holidays, and the pay for them if worked; (6) apprentices' conditions, etc; (7) rules as to the time and mode of paying wages, if any; (8) termination of employment. Clauses may also be found with provisions peculiar to the industry in question—e.g. in the building trades, to provide for the sharpening of the workman's tools, the safety of the lock-up, and travelling time and money, where thought fit; in the shop-workers' awards (where pay is by the week) clauses deal with absence without leave, lodging with the employer, etc.; and special clauses and exemptions for particular phases or sections of the industry are added if need be. Finally, the duration of the award may be for any period up to three years. The validity of all special clauses depends, other things being in order, upon whether they deal with industrial matters (see definition below).

The award comes into force upon gazettal and is thereafter policed by the self-interest of the parties to it and by the department of labour and industry, which has a body of inspectors for the purpose. Breaches of award are punishable, and back wages are recoverable in the court of the industrial magistrate, subject to appeal to the industrial court.

The *'Court of Industrial Arbitration'* is the full style and title of the court established by the acts now in force. Known under the act of 1901 as the court of arbitration, in 1908 recreated as the industrial court, it has from 1912 been known by its present title. It consists of a senior judge with special rights and privileges, and three additional judges. In reality the court has been continuous since 1901, Mr. Justice Cohen, the first arbitration judge, having been succeeded by Mr. Justice Heydon before the first act lapsed, and that judge having continued to occupy the bench to the end of 1918. The office of industrial registrar created by the earlier acts was under the supervision of the minister for justice. It has now developed into a department of labour and industry, under a minister and a permanent under-secretary. It is charged (*a*) with the administration of the Industrial Arbitration Act of 1912 and amending acts; (*b*) with that of a great deal of industrial legislation outside the arbitration system, notably the early closing acts, factories and shops acts, gas act, workmen's compensation act and many others; (*c*) with the maintenance of a centre of public intelligence with regard to industrial law and certain economic features of industries, the publication of the *Industrial Gazette* and *Labour Exchange Supplement*, the control of various State agencies for labour exchange, the provision of labour for government works, and the training of women and youths for rural employment, relief, etc. In this department is housed the board of trade created by the amending act (No. 16 of 1918) already described. The *Industrial Gazette*, first issued in July 1912, was prepared and edited by the industrial registrar; it published all awards in force in New South Wales at the time of the commencement of the act of 1912, and all new awards published up to 1 July 1912, with a compendium, and has been continued as a monthly publication ever since.

In New South Wales 'industrial matters' mean matters or things affecting or relating to work done or to be done, or the privileges, rights or duties of employers or employees in any industry, but not involving questions which are or may be the subject of proceedings for an indictable offence. Particularly the phrase includes wages, allowances or remuneration of persons employed in any industry, or the piecework contract or other price payable in respect of such employment; the allowance or forbidding of piece-work or any other system of payment by results, etc.; the hours, age, sex, qualifications or status of employees, and the modes, terms and conditions of employment; the employment of children and young persons, the giving of preference to unionists, and any established usage or custom in any industry.

It is perhaps in relation to wages and hours that the facts of industrial awards are most forced upon public attention, though the utility and effect of award provisions upon other matters is probably of even greater importance. How great the increase of wages has been, the two following instances will show. In Newcastle Wharf-labourers' Union *v.* Newcastle and Hunter River S.S. Coy. Ltd. (*New South Wales Arbitration Reports*, vol. i. p. 1)—the earliest reported case of the court as first constituted in New South Wales—it is recited in the judgment of the president that 'the men in February 1900 formed themselves into the ———— Union, and in May 1900 struck for an increase of wages and shorter hours, which resulted in the Company granting a wage of 42s. per week of 60 hours, with overtime at the rate of 1s. per hour after 60 hours and of 1s. per hour for Sundays

and holidays. Though the men may not have worked 60 hours, they were entitled to the 42s. if they were not wilfully absent when required. Not content with these conditions the men struck again in October 1900, and it was then agreed that their pay should be on the basis of the Union rules, viz., 1s. per hour for work done in the ordinary hours, and 1s. 6d. per hour overtime, with a further provision of 1s. 6d. per hour for the following holidays, January 1 and 26, Easter Monday, Queen's Birthday, 8-Hour Day and Prince of Wales' Birthday, and 2s. per hour for Good Friday and Xmas Day.' In this case the company was found to have improperly attempted to break away from the agreed conditions, and an award was made fixing the system and rates as agreed above. But by the end of 1918 wharf-labourers employed by the hour had been awarded minimum rates for ordinary hours of 1s. 9d. and 2s. per hour and in 1922 2s. 9d. per hour—with, in each case, correspondingly higher rates for overtime and for certain cargoes. In the sawmilling industry, for which the first award was made in 1905 by Judge Heydon (one of his first awards), the labourer in a timber-yard, if he was also without experience in the industry, was awarded a minimum wage at the hourly rate of 9d. (6s. per day of 8 hours). By the end of 1917 the wages of these labourers had risen to 10s. 1d. per day, and at the end of 1922 to 82s. by the week. The unskilled worker has thus in 16 to 18 years obtained steady advances in pay up to 100 per cent and more above his pre-arbitration rates; but wages of carpenters and joiners, bricklayers, stonemasons, plumbers and plasterers, engineers, blacksmiths, and other skilled artisans if put together and averaged, would not show between 1904 and the end of 1918 an all-round increase of 50 per cent. They increased at a greater rate between 1918 and 1922.

Shortly after the introduction of the system it became necessary to discover and work upon a standard minimum living wage for the humblest adult male worker, to which other wages would be more or less directly related. The first judgment which provided a definite basis upon which boards in New South Wales worked was that of Mr. Justice Higgins (of the federal court) in the Harvester case, about the end of 1907; he favoured a minimum wage of 7s. per day. In 1908 many New South Wales boards took this result as a starting-point. In 1911 Judge Scholes of the New South Wales court increased this 'basic' wage to 7s. 6d. (*in re* Milk Carters' Award 10, *Industrial Arbitration Report* 639). In 1913 Judge Heydon undertook an exhaustive inquiry into the cost of living, and early in 1914 pronounced in favour of a basic wage of 8s. per day, to be increased by a 'prosperity' allowance of 6d., 9d. or 1s. according to the work. This inquiry was a monumental work, valuable to students of industrial law in New South Wales (14 *Industrial Arbitration Report* 22). During the war the prosperity allowance was recalled, but the basic wage was in New South Wales raised by successive stages to 8s. 9d., 9s. 3d., and 10s.—or £3 per week for adult male workers, and £1 10s. for females; towards the end of 1923 it was fixed at £4 2s. for males and £2 2s. for females. These last orders were made by the board of trade, to which such inquiries are now assigned. The intermediate steps from 1914 to 1918 are detailed in Russell's *Australian Industrial Problems*.

Hours were already in most well-organized callings standardized at 48 before the advent of industrial arbitration (see EIGHT-HOUR SYSTEM). But in many industries longer hours were usual; in particular, ferrymen and delivery carters, very many shop-assistants, and many others worked up to 70 hours, even to 90 where the work was not very strenuous. Now by the action of industrial tribunals, and also by the Eight Hours Act of 1916 (passed for that purpose) a normal week is recognized in all industries as consisting of not more than 48 hours' work. In a few special industries shorter hours are prescribed, and legislation is in hand (1925) to make 44 hours' work a normal week. In reducing the hours of work the Commonwealth court has gone farther than the State court. In very few cases, if any, is overtime forbidden, but the award rates for it are nearly always expensive, and excessive overtime is otherwise prevented by regulation where desirable.

Awards are not good in law if they contravene the express provisions of statutes, but they may deal with the subject matter of an act of parliament in such a way as not to contravene its provisions. Apart from what is here noted, the interpretation of 'industrial matter' is very wide—wide enough, for example, to embrace the awarding of annual holidays, the abolition of night shifts, and the application of the card system in any industry.

Victoria.—The arbitration system in Victoria, while slightly older, is simpler and less developed than that of New South Wales. The most notable difference is that it contains no anti-strike legislation; and strikes in Victoria have been markedly fewer than in New South Wales. If, however, a wages board determination is in force in a trade, it can be suspended for any time up to 12 months.

In Victoria the system is a portion of the factories and shops legislation, and dates from 28 July 1896, when act No. 1445 (Factories and Shops Act 1896) made provision for the creation of special boards to fix the minimum prices or rates which might be paid to persons preparing articles of clothing or furniture or bread making or baking (sec. 15). From these special boards, designed to interfere between employer and employee in certain sweated industries, the Victorian wages board system has been developed. Before 1896 factory and shop legislation in Victoria was of the same character as that of the United Kingdom and of New South Wales.

The development of the system in Victoria has been mainly under the guiding hand of one man, Sir Alexander Peacock, who introduced the first wages boards and administered the law for the greater part of the 20 years following. The process included (1) a succession of amending acts tending to enlarge the system—e.g. act No. 1804 (Factories and Shops Continuance Act 1902) in which the legislature dealt directly with vexed questions that had arisen during the early working of boards, and act No. 1857 (Factories and Shops Act 1903) which created the court of industrial appeals; (2) the development, by judges confronted with new problems, of principles both from the facts of the cases and from the nature of the duties committed to their court—e.g. the judgments of Judge Hood *in re the Bread Board* (13 *Argus Law Reports* 589) upon the principles and evidence on which the minimum wage should be fixed, distinguishing temporary and fluctuating grounds from those which may be regarded as established or permanent, and to the effect that wages which compare favourably with those

awarded in other States should not be increased, and *in re the Starch Board* (ibid. 558) upon dealing with each trade on its own facts and upon the existence and effect of competition among employers.

The present law of Victoria on the subject is found in the Consolidated Factories and Shops Act of 1915, No. 2650. Part VII deals with the appointing of boards, part VIII with the court of industrial appeals, part IX with apprentices and improvers; parts X and XI expressly legislate for some topics which in New South Wales, under the heading 'Industrial matters,' are relegated to industrial boards or to the court or industrial registrar as the case may be—e.g. old, slow and infirm workers, and holidays in certain callings. Under this law special boards are continued, or can be created for any process, trade, business or occupation. Half the members of each board represent employers, half employees, and the whole body nominates its chairman. In default of nomination the appointment is made by the governor in council on the recommendation of the minister. Each board consists of not less than four, nor more than ten, members and the chairman. The appointments are for three years. These boards determine the minimum rates of pay by piece-work or time (or both), and the hours of work; may prescribe the forms of indenture of apprenticeship, and may vary the hours to be worked and the overtime fixed in other parts of the act. They deal with trades or groups of trades; and 'trade' includes process, trade, business or occupation (sec. 134). A resolution of both houses of parliament is necessary before special boards can be created for industries not already within the system. The boards are less numerous and have on the whole less power than in New South Wales.

The court of industrial appeals is established by section 174. It consists of a president and two others. The president is to be a judge of the supreme court, and is to sit in every court of industrial appeal constituted from time to time. The other members represent each side of the industry from whose special board the appeal has been brought. Besides hearing appeals, the court of industrial appeals can deal with matters referred to it by the minister.

Other States.—South Australia has a system of wages boards of the same kind as Victoria, and since 1912 has had an industrial court authorized to supervise that system, as in New South Wales; it closely resembles the court of industrial arbitration of New South Wales, and the Commonwealth court of conciliation and arbitration. In particular it has the power, possessed by the Commonwealth court, but not by that of New South Wales, of calling a compulsory conference in any industry to avert a strike. The system includes punishment for strikes and lockouts, and as a whole has worked well.

In Queensland wages are regulated by a court, not by wages boards. Anti-strike legislation is provided, forbidding strikes except upon notice, after an interval of 14 days, and after a secret ballot; in the case of public utilities there must also have been a conference held before an industrial judge (Industrial Peace Act of 1912-13). Queensland appears to have been the first country in the world to provide by law for a secret ballot before striking, to be taken by State officials.

Western Australia also has an industrial court without wages boards. Anti-strike legislation is included. See the Industrial Arbitration Act of 1912.

Tasmania has a wages board system, with anti-strike clauses in the act.

See on the general question Judge Higgins's *A New Province of Law and Order*, H. M. Murphy's *Wages and Prices in Australia*, and F. A. A. Russell's *Australian Industrial Problems*. The most important official documents are the *Commonwealth Arbitration Reports*, published annually; the *New South Wales Industrial Arbitration Reports* (annual), and the *New South Wales Industrial Gazette*, published monthly. For Victoria see the *Argus Law Reports* and *Victorian Law Reports* (annual volumes), and for South Australia the *South Australian Industrial Reports*, in 5 vols. up to the end of 1922. F.A.A.R.

Innes, Frederick Maitland (1816-1882), born in Scotland in 1816, migrated to Tasmania in 1833, and after a time became editor of the *Observer*. Elected to the first legislative assembly in 1856, he was treasurer of the Weston-Smith-Weston-Chapman ministries (1857-1862), resigning only to become colonial secretary in the last, with a seat in the council. He subsequently became first chairman of committees and then president of the council (1868-72). Between 1872 and 1876 he was again in office, sometimes as premier and sometimes as treasurer (under Alfred Kennerley), during a very difficult period of the colony's existence; his name is especially connected with considerable additions to the powers of municipalities and similar bodies. In 1880 he was again made president of the council, and died on 11 May 1882.

Innes, Sir Joseph George Long (1834-1896), born at Sydney on 16 October 1834 and educated at the King's School, Parramatta, was in 1851 taken into the survey office and in December of that year transferred to the department of justice and made clerk of petty sessions at Sofala on the Turon, then a populous mining settlement. From 1854 to 1856 he was associate to Chief Justice Stephen; in the latter year he went to England to study law and on 17 November 1859 was called to the bar at Lincoln's Inn. Returning to Sydney, he was in 1863 admitted to the New South Wales bar, and in 1865 accepted a district court judgeship in Queensland; this he held until 1869. In 1872 he entered the legislative assembly of New South Wales as member for Mudgee, on 14 May joined the first Parkes ministry as solicitor-general, in August 1873 resigned his seat, in September was nominated to the council, and on 20 November became attorney-general. In 1874 he accompanied Sir Hercules Robinson to Fiji to negotiate the cession of the islands to Great Britain, and was offered, but refused, the chief-justiceship of the new colony. Leaving office in February 1875, he was appointed chairman of committee of the council; this post he retained until 10 August 1880, when he became minister of justice in Parkes's third ministry. In October 1881 he was appointed to the supreme court of New South Wales, and was still in harness when he died on 28 October 1896. (Kt. Bach., 1875.)

Insects, vernacular name of the class Insecta, of the phylum Arthropoda, invertebrate animals with a segmented body and jointed appendages. About 470,000 species have as yet been described, 37,000 of these being indigenous to Australia; but this number falls far short of the total number known to exist. The class is to be recognized by the division of the body into three parts, head, thorax, and abdomen, and by the

presence of three pairs of legs and usually two pairs of wings, attached to the thorax.

In classifying the Insecta, the most important characters are the structure of the wings and mouth-parts, and the details of the life-history. For the purpose of this article we may conveniently adopt a modification of Handlirsch's recent arrangement, bringing it more into accord with the older systems of Packard and Brauer.

Class Insecta. Sub-class Apterygota (insects which do not possess wings, and which have never at any time in the course of their evolution possessed any).

Order 1. Thysanura (silver-fish, bristle-tails). Abdomen with ten segments; no ventral tube or spring present.

Order 2. Collembola (spring-tails). Abdomen with only six segments at the most, the first carrying a ventral tube beneath it, and the fourth or fifth a spring.

Sub-class Pterygota (insects which either possess wings, or, if not, have once possessed them in the course of evolution).

Division Hemimetabola (insects not possessing a resting-stage, or true pupa).

Order 3. Orthoptera (cockroaches, earwigs, grasshoppers, crickets, mantids, stick- and leaf-insects). Mouth-parts formed for biting (mandibulate). Fore-wings tough and leathery (tegmina); hind-wings delicate and of much greater expanse, with a broad anal fan.

Order 4. Isoptera (white ants, web-spinners). Mouth-parts mandibulate. Wings delicate, placed wide apart, nearly always similar in form and with weak venation.

Order 5. Psocoptera or Copeognatha (psocids). Mouth-parts mandibulate, but with a hard pick or chisel developed from the maxilla. Wings delicate, with very simple venation; the hind-wing smaller than the fore. This and the following order are by some authorities classed together as Corrodentia.

Order 6. Mallophaga (biting-lice). Dorso-ventrally flattened, secondarily wingless parasites upon mammals and birds. Mouth-parts mandibulate.

Order 7. Anoplura (sucking-lice). Dorso-ventrally flattened, secondarily wingless parasites upon mammals. Mouth-parts used for sucking, by development of the hypopharynx into a sucking-tube.

Order 8. Thysanoptera (thrips). Wings delicate, equal, without any clear venation, and with a strong fringe of hairs. Mouth-parts abnormal, secondarily developed from a mandibulate type for sucking and piercing.

Order 9. Hemiptera (bugs, cicadas, hoppers, scale-insects, plant-lice). Wings unequal, the fore-wing narrower and longer than the hind, and of tougher consistency. Mouth-parts formed entirely for sucking.

Order 10. Perlaria (stone-flies). Wings reticulate, unequal, the hind pair with an anal fan. Antennae very long. Mouth-parts mandibulate, or the mandibles much reduced. Larvae aquatic, the tracheal system completely closed, without spiracles.

Order 11. Plectoptera (May-flies). Wings reticulate, the hind pair very small or absent. Antennae very short. Mouth-parts atrophied. Larvae aquatic, with paired lateral gills on abdomen. Winged insect emerges as a sub-imago, from which the imago emerges later on.

Order 12. Odonata (dragonflies, damsel-flies). Wings reticulate, either equal (Zygoptera) or somewhat unequal (Anisoptera). Antennae very short. Mouth-parts mandibulate, the maxillae also hardened in part for biting. Larvae aquatic, with caudal or rectal gills; the labium forming a prehensile mask.

Division Holometabola (insects with a resting stage or true pupa. This stage may be either a *pupa libera*—i.e. one in which the wings are not soldered down—a *pupa obtecta*,—i.e. one with wings and appendages soldered down—a *pupa incompleta* (intermediate between *libera* and *obtecta*), or a *pupa coarctata*, i.e. a *puparium* formed from the hardened larval skin, inside which a true pupa is formed).

Order 13. Coleoptera (beetles). Fore-wings forming a hard convex covering (elytron), useless in flight. Mouth-parts mandibulate. Resting-stage a *pupa libera*; more rarely a *pupa incompleta*.

Order 14. Hymenoptera (ants, bees, wasps, saw-flies, etc.). Wings membranous, unequal, the hind being the smaller; closely linked together by a series of hooks during flight. Mouth-parts mandibulate, but with an elongate tongue developed in the higher forms for sucking nectar. Resting-stage a *pupa libera*, preceded by a sub-pupa, and enclosed in an oval cocoon.

Order 15. Megaloptera (alder-flies, snake-flies). Wings membranous, somewhat unequal, with open reticulation. Mouth-parts mandibulate. Larvae mandibulate, either aquatic (Sialioidea) or terrestrial (Rhapidioidea). Resting-stage a *pupa libera*, lying free in the earth, and active before metamorphosis.

Order 16. Planipennia (lacewings, ant-lions). Wings sub-equal, with or without reticulation, the veins hairy, with their terminations on the wing-margin nearly always split into fine branchlets. Mouth-parts mandibulate. Larvae with suctorial mouth-parts. Resting-stage a *pupa libera*, enclosed in a cocoon spun from the anus.

Order 17. Mecoptera (scorpion-flies). Wings equal, with hairy veins, and fine hairs upon the membrane also in most cases; moderately reticulate, with dichotomic branchings of the veins. Mouth-parts mandibulate, but with the mandibles either spear-like or absent. Larvae a caterpillar, with compound eyes, and generally also pro-legs upon abdominal segments 1-8. Resting-stage a *pupa libera*, lying free in the earth, or in an earth-cell.

Order 18. Trichoptera (caddis-flies). Wings sub-equal or unequal, with dense hairs upon the veins and membrane. Mouth-parts much reduced, only the labrum and the two pairs of palpi being present. Larva aquatic, caterpillar-like, but with no pro-legs except the anal pair; usually living in a case constructed of foreign material. Resting-stage a *pupa libera*, often enclosed in a gelatinous cocoon, and swimming actively before metamorphosis.

Order 19. Lepidoptera (butterflies and moths). Wings densely clothed with scales; either similarly veined (Homoneura), or with the hind-wing reduced in size and venation (Heteroneura). Mouth-parts with the mandibles almost always absent, the maxilla usually developed into a long sucking-tube (haustellum). Larva a caterpillar, nor-

mally with five pairs of abdominal pro-legs. Resting-stage generally a *pupa obtecta.*

Order 20. Diptera (two-winged flies). Hind-wings reduced to minute balancers (halteres). Mouth-parts originally mandibulate, but the mandibles either spear-like or absent; a sucking-apparatus developed from the labium in the form of a proboscis. Larva variable in form, but always without thoracic legs. Resting-stage either a *pupa incompleta* (Orthorrhapha) or a *pupa coarctata* (Cyclorrhapha).

Order 21. Aphaniptera or Siphonaptera (fleas). Laterally flattened, secondarily wingless, active, jumping parasites upon mammals. Mouth-parts developed for piercing and sucking. Larva without thoracic legs. Resting-stage a *pupa libera.*

Institute of Science and Industry. See SCIENCE AND INDUSTRY, COMMONWEALTH INSTITUTE OF.

Ipomaea, a large genus of the family Convolvulaceae, consisting of trailing or twining herbs or shrubs, chiefly tropical or subtropical; a few species are found in temperate countries. The trailer *I. pes-caprae* is coastal in most countries, and in Australia extends from New South Wales to northern Australia. It has bilobed leaves, with stalks exceptionally variable in length, and large showy pinkish flowers. In India a decoction of the leaves is used in cases of rheumatism, and the Fijians roast them for caulking canoes. It is an ornamental plant and a useful sand-binder. *I. palmata,* a blue-flowered trailer, which ranges from New South Wales to Queensland, is the 'Egyptian bindweed.' *I. batatas,* the Sweet Potato of South America, is well adapted for cultivation in southern Australia.

Iridaceae, a family of herbs with tuberous roots or rhizomes, found all over the world and especially plentiful in South Africa. Five genera with 24 species are indigenous to Australia. The endemic genus *Patersonia* consists mainly of tufted herbs with blue (rarely yellow or white) flowers. The flowers are packed in a head and enclosed between two leathery bracts—they open one at a time and last for a short period in sunshine, or a whole day in cool weather; fruit a capsule, with several two-valved cells, which explode with considerable violence when ripe and expel the seeds to a distance. *Libertia,* four species of which are indigenous, extends to New Zealand and South America; *L. paniculata,* a brush gully herb which ranges from Victoria to Queensland, has very showy white flowers.

Irish Exiles. This name has been given to three bodies of Irish political prisoners who were transported to Australia.

The Exiles of 1798. O'Connor Morris in his *History of Ireland* (1898), speaking of the insurrection of 1798, says:—'After a few severe examples had been made, the conspirators who had fallen into the hands of the Irish government were amnestied under not unfair conditions; their lives were spared, but they had to leave the country. They were none of them men of marked powers; but some won honour in foreign lands; two or three gallantly followed Napoleon's eagles; more than one made a name for himself in America.' Many of these men, along with others under legal sentence, were sent out to Australia in 1800 and 1801, and some as late as 1806. Amongst them were Joseph Holt (q.v.), a general of the Irish insurgent army; Henry Fulton (q.v.), a Church of England clergyman; James Meehan (q.v.), afterwards deputy-surveyor-general; Father Harold and Father O'Neil, Roman Catholic priests; William Alcott, an officer of the British army on full pay; Michael Dwyer; and William Davis, one of the makers of rebel pikes.

King, who at first believed them to be 'desperate and diabolic characters,' found after a short experience that the great majority were quiet and orderly; but a good deal of trouble resulted from the fact that, while some of those transported had been legally sentenced, no record of the sentences of others was in existence —they had simply been court-martialled, sent to a military depot during the rebellion, and (as the lord lieutenant of Ireland admitted) 'embarked by the officer commanding there without any trace of such proceeding having been anywhere recorded.' Unfortunately in March 1804 a number of the more ignorant Irish convicts mutinied at Castle Hill, and King's suspicions of the whole mass returned with greater vigour; but when the ringleaders had been sent to Norfolk Island the rest quietened down again, and the 'exiles' were gradually absorbed into the population either as emancipists or (where no legal sentence had been recorded) as free settlers.

Young Ireland Exiles.—After the Irish insurrection of 1848 several of the men associated with it were sentenced to penal servitude, and, with one exception, were sent to Tasmania. The exception was John Mitchel, who was deported to Bermuda, but afterwards rejoined his companions in misfortune. Among those transported were William Smith O'Brien, Thomas Francis Meagher, Terence Bellew MacManus, Patrick O'Donoghue, John Martin and Kevin Izod O'Doherty; the four first mentioned were prisoners for life; O'Doherty's term was 14 years; the same sentence had been incurred by John Mitchel and John Martin, but their legal offence was less serious.

Six years after their transportation an amnesty was extended to the three (O'Brien, Martin, and O'Donoghue) who still remained in Tasmania; the other three had escaped, MacManus in 1851, Meagher in 1852 and Mitchel in 1853. Meagher and Mitchel were said to have broken their parole, but Mitchel's partisans repelled the accusation and boldly contended that he had behaved in no way inconsistent with the code of honour; he had given warning of his intention to fly, and had afforded the local magistrate an opportunity of arresting him. What actually took place was that Mitchel, accompanied by the friend who had planned his escape (P. S. Smyth, afterwards a member of the house of commons), rode up to the police court at Bothwell, handed his ticket of leave to the presiding functionary, announced that he was going to escape, and made off before the magistrate had recovered from his surprise. Sir William Denison, then governor of Tasmania, took a very different view of the matter, declaring that Mitchel had sacrificed all claim to courteous treatment and, if recaptured, would be sent to hard labour. Sir William had held similar views with regard to Meagher and MacManus. The most interesting account of these 'exiles' is the *Jail Journal* written by Mitchel, and published after his escape to America.

The Fenians.—In 1867 Western Australia was the only penal depot left in Australia, and some

60 Fenian prisoners were sent there, including a number of ex-soldiers, the most notable of whom was John Boyle O'Reilly. The Fenian societies in America, naturally full of sympathy for men whom they regarded as martyrs, took measures for the rescue of the deported prisoners. Some of the more reckless spirits talked about making a descent in force on Western Australia, but they did no more than talk. The first prisoner who contrived to break bounds and elude pursuit was John Boyle O'Reilly, who had been apprised of the fact that at a certain time an American whaling vessel would be cruising off the coast, and would receive him on board, provided he was outside Australian waters. He made two attempts to reach her, but she did not appear; then, his friends having persuaded the captain of another whaler to be on the look-out, he reached the vessel safely, and escaped to America, where he achieved distinction as a journalist and man of letters. Six other Fenians escaped later in the same way.

Iron. The existence of deposits of iron ore in Australia was known from almost the earliest days of British settlement. William Kent took specimens of ore to England in 1800, and in 1812 Simeon Lord proposed to open a mine in northern Tasmania. In 1852 ironworks were established near Mittagong, to smelt ores described below; in 1875 works at Lithgow, just west of the Blue Mountains, attempted to smelt local and western district ores; but little actual progress was made until in 1908 an act of the federal parliament provided for the payment of bounties on pig-iron made from Australian ore and bar iron and steel made from Australian pig-iron. The resulting industries in the six States are most conveniently dealt with separately.

In *New South Wales* the first attempt to manufacture pig-iron was made at the Fitzroy ironworks near Mittagong. No complete account of the quantity of pig-iron manufactured is available; in returns published in the annual reports of the department of mines (1876-1886) mention is made of amounts that total 13,313 tons, but these returns are obviously incomplete. The Fitzroy iron deposit is situated 60 miles from Sydney, close to the road running between Sydney and Goulburn. The bright red and yellow oxides upon the surface must have always made it noticeable to travellers, and the neighbouring chalybeate spring would add to the interest. The deposit is composed of an excellent brown ore; coal-seams underlie it, and outcrop in the neighbouring valleys; good limestone can be obtained within 40 miles. It is, therefore, not surprising that the first ironworks should have been erected in this vicinity.

The land on which the ore occurs was applied for in 1848 by John Neale, Samuel Holmes, and William Burton, who formed a syndicate, erected a small blast furnace, and imported skilled workmen from England. The works were opened in 1852 by Sir Charles FitzRoy, then governor. Smelting operations were carried on at intervals during two or three years, but eventually discontinued as unprofitable. In 1859 the works were leased by B. W. Lattin and the brothers Hughes; they built a blast furnace which is still standing, and erected blowing engines. 'Anthracite' coal, obtained from the Nattai valley, and charcoal were used as fuel; but again smelting operations did not proceed satisfactorily, and very little iron was produced. In 1864, however, the works were taken over by Ebenezer Vickery, John Keep, and Simon Zollner; they put a Mr. Hampshire in charge, and under his management considerable progress was made. He introduced the hot blast, erected puddling furnaces and rolling mills, and succeeded in making a quantity of iron. Many castings were sent away from the works, among them cylinders for the Gundagai bridge, and girders for Vickery's Chambers in Pitt-street, Sydney. But the cost of production was £5 17s. 6d. per ton of pig-iron; the works were shut down in April 1866, and mine and works sold in 1870 to John Fraser.

In 1875 the works were taken over by the 'Fitzroy Bessemer Steel and Hæmatite Iron and Coal Company,' and the management was given to David Smith, who brought with him from England smelters and other skilled workmen. He also laid down a tramway between the works and the Nattai valley coal-mines. As before, however, very little iron seems to have been made, and the management in 1876 passed into the hands of David Lawson; he, recognizing the inferior quality of Nattai anthracite, obtained his coal and coke from Bulli and Lithgow, and between February 1876 and March 1877 produced 3242 tons of pig-iron at an average cost of £5 per ton.

At Lithgow the foundation of the blast furnace was laid on 1 January 1874. Smelting operations commenced in October 1875, and were carried on intermittently for several years, about 22,000 tons of pig-iron being produced. The ore was obtained partly from clay bands occurring in the district, and partly from brown and magnetic ores obtained from Newbridge and Blayney. The greater portion of the pig-iron was converted upon the ground into castings, bars, angle iron, and iron rails. The large bed-plate, and the fly-wheel now in use at the works, were both manufactured from iron produced from New South Wales ores. But the operations were not financially successful, so that smelting was discontinued after a few years, and the blast furnace was pulled down. The works were then for a short period carried on co-operatively by a body of workmen, the rolling mills being chiefly employed in re-rolling old iron rails. In 1885 the works were taken on lease by William Sandford, who was vigorously supported by James Rutherford (q.v.) of Bathurst; considerable progress was made, and large quantities of scrap iron were worked up into bars, sheets, etc. A sheet mill, a galvanizing plant, and machines for the manufacture of railway spikes were erected, a Siemens steel furnace was added to the works, and in it steel was manufactured for the first time in the colony.

On 1 January 1908 C. H. Hoskins purchased the Lithgow ironworks as they stood. The plant at that time was antiquated and inefficient, with the exception of a new blast furnace that had recently been installed. At the time of taking over it consisted of a blast furnace with three stoves (making 700 tons per week); one 15-ton and two 4-ton basic New Form Siemens furnaces; one 24-inch mill, reversing by means of clutches (this had never been worked and was quite useless); one 18-inch two-high pull-over mill; one 14-inch muck-bar mill; one 14-inch two-high pull-over bar mill; one small 9-inch three-high guide mill. The main operation was the rolling of wrought-iron piles and puddled bar from eight puddling furnaces. The Hoskins Company, however, decided to concentrate on the production of steel. Ironstone was obtained from Carcoar, and in the first year 3946 tons

of steel ingots were made, as well as over 30,000 tons of pig-iron from 51,206 tons of local ore. The amount varied from year to year, mainly on account of occasional industrial troubles, but in 1908-13 the average annual yield was 3811 tons of steel (despite the fact that in 1912 no steel at all was made), and over 36,000 tons of pig-iron from about 60,000 tons of ore. On 1 January 1909 a system of bounties (12s. per ton of pig-iron or steel made from Australian ores) came into force, and up to the end of 1913 the Lithgow works received £105,849 from this source. In 1914 the rate of bounty was reduced to 8s. per ton, but production nearly doubled; in 1914-7 the average annual production was 22,472 tons of steel, and 62,262 tons of pig-iron from 113,027 tons of ore. Published figures for 1918-22 show a yearly output of 76,003 tons of pig-iron from 138,039 tons of ore.

In connection with the Eskbank ironworks the company operates a colliery at Dapto on the coast and another at Lithgow, as well as two cast-iron pipe manufactories in the precincts of Sydney. It owns many iron properties in New South Wales and Tasmania; hitherto the ore has been obtained from mines at Tallawang near Gulgong (a magnetite containing 60 per cent of iron), Cadia SW. of Orange (a red hematite containing 57 per cent of iron), and Carcoar SW. of Blayney (a similar hematite). High-grade ferro-manganese is also produced from ore obtained at Grenfell near Young. The Lithgow plant now includes 2 blast-furnaces with 8 stoves; 3 basic open-hearth furnaces, with a weekly capacity of 3000 tons in all; a 28-inch blooming and finishing mill with a capacity of 4000 tons of rails or billets per week; and three bar mills (one 18-inch two-high pull-over, one modern 10-inch guide mill, and one 9-inch guide mill).

In 1900 the Broken Hill Proprietary Company (for which see BROKEN HILL) acquired deposits of iron ore, showing 66.68 per cent of metallic iron, at Iron Knob and Iron Monarch on the western side of Spencer Gulf in South Australia. Originally it had been intended to use the ore as flux in the company's Port Pirie smelters; but in 1911 it was decided to exploit the deposits for the manufacture of iron and steel, and in 1915 works were opened at Newcastle—that site being chosen because the Newcastle-Maitland coal was considered the most suitable for use in the furnaces. By the end of August in that year 36,214 tons of pig-iron had been produced; in the following eight months 86,000 tons of steel were made; and up to the end of 1921 the production of steel ingots averaged about 190,000 tons annually. Industrial disturbances then caused the closing down of the works, but in 1923, when they were reopened, 147,115 tons of steel were made in six months. During the war the works furnished rails for South African railways, rails and munition bars for the Imperial war office, rails for the transcontinental railway between Port Augusta and Kalgoorlie, and plates, joists, and bulb angles for vessels built by the Commonwealth in Australia. The plant includes four blast furnaces, nine basic open-hearth furnaces of about 600 tons capacity in all, a 35-inch blooming mill, a 28-inch rail mill, three merchant mills (18-inch, 12-inch and 8-inch), and a continuous rod mill. Several subsidiary industries—e.g. the manufacture of nails, wire, wire-netting, wire ropes, black and galvanized iron sheets—have sprung up round the Newcastle works.

In 1901 J. B. Jaquet, geological surveyor, tabulated the New South Wales deposits as follows:—

District.	Description of ore	Estimated minimum quantity in tons.
Breadalbane (near Goulburn)	brown ore and hematite	700,000
Cadia (near Orange)	specular hematite, magnetite, and carb. ore	39,000,000
Carcoar	hematite and brown ore	3,000,000
Chalybeate spring deposits of Southern district	brown ore	1,510,000
Cowra	magnetic ore	100,000
Goulburn	brown ore	1,022,000
Gulgong	magnetic ore	120,000
Mandurama and Woodstock	brown ore	609,000
Marulan	brown ore and hematite	40,000
Mudgee	brown ore with manganese	150,000
Newbridge, Blayney and Orange	brown ore and magnetic ore	150,000
Queanbeyan	magnetic ore	1,000,000
Rylstone and Cudgegong	brown ore	443,000
Wallerawang and Piper's Flat	brown ore	200,000
Williams and Karuah River	titaniferous magnetic ore	1,973,000
Wingello	aluminous ore	3,000,000
		53,017,000

In *Victoria* a good deal of ore has been located, but very little use made of it. Professor Krause estimates the Lal Lal deposit (near Ballarat) at 750,000 tons of available ore containing 68 per cent to 70 per cent oxide of iron, 16 per cent of silica, and a trace of phosphorus. Deposits of hematite, with which is associated magnetite and specular iron, occur at Nowa Nowa in Gippsland. About 1875 a small experimental blast furnace was erected at Lal Lal, and a small quantity of pig-iron produced. But the lack of accessible coal makes it impossible for the present to smelt the ore cheaply.

In *Tasmania* (where the existence of ore has been known since 1812) the British and Tasmanian Charcoal Iron Company, formed to exploit deposits in the Beaconsfield district, commenced operations in 1876. A sum of £80,000 was expended in erecting works, and several hundred tons of pig-iron were produced, but it contained 5 per cent of chromium and was therefore not adaptable to ordinary uses. Still, in about 10 months from 2000 to 3000 tons of pig-iron were produced, and in 1877 the output was about 250 tons per week, containing from 2 to 10 per cent of Cr_2O_3. This was used by Mel-

bourne ironfounders for making battery shoes, dies, and other articles requiring hardness and toughness; but there was only a limited local market, and operations were suspended. In 1908 3600 tons of ore were raised at Penguin, west of the Mersey River, but no smelting has been done locally.

The Tasmanian geological survey estimates the State's deposits as follows:—

	Potential tons.
Blythe River	17,000,000
Dial Range and Penguin	700,000
Beaconsfield and Anderson's Ck.	1,300,000
Long Plain	20,000,000
Zeehan	2,900,000
Nelson River	Unknown
Total	41,900,000

The Blythe River deposits seem the most important. An analysis quoted by the government geologist shows that the iron contents vary from 46 to 68.7 per cent, the silica contents from 1.6 to 34.2, and the phosphorus contents from 0.04 to 0.09. The Commonwealth government in 1919 engaged three mining engineers to report on this property, but they reported that the lode-matter as a whole was too siliceous for commercial purposes.

In *Queensland* there are deposits of specular iron, hematite and magnetite in the Cloncurry district; one at Mount Leviathan is about 200 feet high, and a quarter of a mile in diameter at its base. Its geographical position, however, makes it at present absolutely valueless. At Mount Biggenden (west of Maryborough) there are high-grade iron deposits from which bar iron of good quality has been produced by Maryborough ironfounders. The estimated quantity of ore available here is 500,000 tons. The deposits at Iron Island in the Rockhampton district are mined to secure fluxes for use at Mount Morgan.

During the war a royal commission was appointed by the State government to enquire into the possibility of establishing state iron and steel works; it reported that the State should at once erect a furnace having a capacity of, say, 150 tons of iron per day, together with extensive by-product recovery coke-ovens and mine equipment. The initial cost should not exceed £150,000. A thoroughly qualified expert should be appointed general manager of the works, and be empowered to choose the most suitable site; he should further investigate (*a*) the advisableness of establishing state steel manufacturing works, (*b*) the cost of such works, (*c*) the local markets, existing and potential, for their product, and (*d*) the possibility of a market for export beyond the State. A general manager has since been appointed, and a site for the works chosen.

The ironstone deposits of *South Australia* are numerous, but only the Iron Knob and Iron Monarch deposits (owned by the Broken Hill Proprietary Company) have been extensively worked. Originally they supplied flux to the lead-smelters at Port Pirie; they are now utilized to supply iron ore for the works at Newcastle in New South Wales. They are situated on the western shore of Spencer Gulf, and are estimated at 130,000,000 tons. Later exploration in the vicinity has proved two more valuable deposits, the Iron Prince and the Iron Baron.

In 1873 a small charcoal furnace was erected near Mount Jagger, about 11 miles north of Victor Harbour. Ore was obtained from an extensive deposit of magnetic iron ore which caps the summit of the mount. But the workmen employed were not sufficiently skilful, the furnace frequently became blocked, and operations were not successful.

In *Western Australia* the most important deposits are at Koolan and Cockatoo islands in Yampi Sound on the north-western coast, between King Sound and Collier Bay. The main deposit stands out abruptly above high-water level to a height, in places, of 600 feet. It has a length of 300 chains and an average width at base of 110 feet, and is estimated to contain 68,850,000 tons of iron ore, averaging about 65 per cent of iron, 6 per cent of silica, .06 of phosphorus, and a trace of titanium oxide. Another deposit at the northern end of the island is estimated to contain 7,800,000 tons, averaging 66 per cent of iron, 5 of silica, .04 of phosphorus, and .35 of titanium oxide.

On Cockatoo Island there is a deposit of hematite outcropping for a length of 110 chains up to 300 feet in height, about 130 feet in width; the estimated tonnage available above high-water level is 13,850,000 tons, averaging about 68 per cent iron and 2 of silica. Another deposit on the northern end of this island is estimated to contain 7,000,000 tons of ore.

Iron ore deposits are widely distributed in this State between Kimberley and the Leeuwin, notably near Nannine, Lake Moore, and Southern Cross; but their geographical position makes most of them useless for the present.

Irrigation and Water Conservation.

The area of the Commonwealth is 2,974,581 square miles; of this area 1,697,911 square miles (57 per cent) have an average rainfall of less than 15 inches per annum, and must therefore be classed as arid or semi-arid. Much, however, of the soil in these districts is suited for intense cultivation if water were procurable, its texture being for the most part a sandy loam, occurring either in plains of fairly uniform elevation or in rolling country interspersed with sand-ridges. Local watercourses are few, but at wide intervals the semi-arid districts are intersected by rivers which have their source in mountain ranges nearer the coast; and along the river-banks are areas of rich alluvium very suitable for lucerne-growing. Owing to the great variations in the distribution and intensity of the rainfall the flow of most inland rivers is very irregular; at one time they are in high flood, at another almost dry or completely so. Only the Murray and such of its tributaries as take their rise in the Southern Alps (in the south-eastern corner of Australia) are regularly snow-fed, and even there no mountains are of sufficient altitude to carry perpetual snow. In these circumstances no extensive systems of irrigation can be developed without the construction of large storage dams, which will conserve the flood-waters for use in the dry seasons. To determine the volume of water discharged annually a systematic gauging of the rivers has been carried on for many years, the daily heights being recorded at a number of stations, and observations taken with current-meters; thus the capacity of storage to be provided, and the regulated flow which can be depended on for irrigation, are accurately estimated in advance.

The development of irrigation schemes in Australia was retarded for many years by the opposition of private riparian interests, which were

governed by the common law of Great Britain; private irrigators had not even such security of priority right in using river-water for irrigation purposes as obtained in the western States of America. Consequently (except by Chinese gardeners, who consistently irrigated their small holdings) little interest was taken in the development of irrigation schemes until 1884, when (following on a destructive drought) commissions were appointed by the governments of Victoria and New South Wales to enquire into water conservation and irrigation.

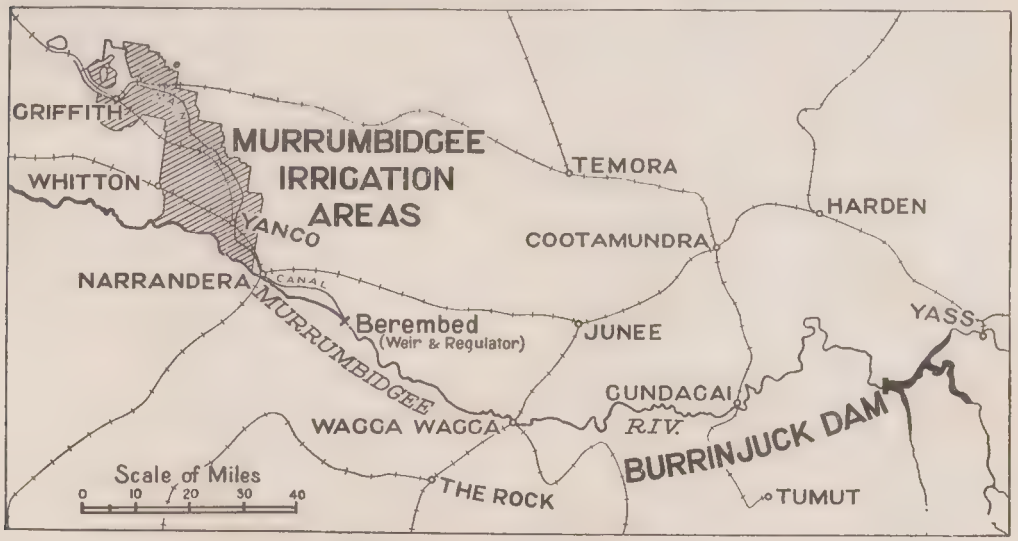
Victoria.—The Victorian commission deputed its chairman, Alfred Deakin (q.v.), who had already investigated irrigation methods in India, to visit the western United States and enquire into the schemes there in operation. His report, submitted in 1885, formed the basis of the Victorian irrigation act of 1886; this vested all riparian rights in the crown, made provision for the declaration of districts most suitable for irrigation and for the construction of headworks of a national character, and made it competent for the government to advance the capital required for local works to trusts formed by settlers in a suitable district. Each trust was empowered to levy such rates upon irrigated land as would cover interest charges at 4½ per cent and a sinking fund of 1½ per cent per annum. In 1887 a beginning was made at Mildura (on the left bank of the Murray, about 16 miles above the Darling junction) in the heart of the mallee country. Two blocks of land of about 25,000 acres each were made available to the brothers Chaffey (q.v.); and they erected the Siki plant which, with its four 6-inch pumps, lifted water from the Murray into a lagoon and thence to the required levels to irrigate 12,000 acres. Irrigation schemes in the Goulburn-Loddon area were developed by trusts. By the end of the century arrangements had been made to intercept the Goulburn by a weir 40 feet in height, and to divert the summer supply into two channels; similar works had been erected on the Campaspe and Loddon rivers and on the south bank of the Murray in this district. Altogether, arrangements for diverting 294,000 cubic feet per minute from the Murray and its tributaries had been completed, either directly by, or with the sanction of, the Victorian government. Owing to the irregularity of the flow, however, the schemes were only partially successful, since preparations had been made to distribute water before it had been conserved. Work on the Waranga reservoir was therefore begun. Before its completion the Victorian government, owing to financial difficulties in which the trusts had become involved, decided to ad-

Irrigation areas, Victoria.

minister directly all irrigation schemes except that at Mildura. By the water act of 1905 (since incorporated in the water act of 1915) a State Rivers and Water Supply Commission was established, and has since pursued a vigorous policy with financial aid from the State government. The most important works under its control are connected with the Goulburn River gravitation scheme, which supplies an area of 870,000 acres in the valleys of the Goulburn, Campaspe, and Loddon either for irrigation or for domestic and stock purposes. The present headwork, a diversion weir on the Goulburn near Nagambie, is constructed of concrete masonry with 21 flood-gates, which raise the upstream water-level 10 feet above the crest. The gates can be lowered in flood-time if necessary to allow of a free discharge of the waters. The weir has a total length (including channel regulators) of 925 feet, and a height of 50 feet. The water is diverted by two main channels, the eastern supplying areas north of the Broken River and the western—which has a capacity of 1700 cubic feet per second—serving to feed distributaries in the Rodney district and to fill Waranga reservoir, the principal storage-basin of the system. This reservoir, which is formed by an earthen embankment 4½ miles long across a natural depression, and covers an area of 22½ square miles to an average depth of 23 feet, has a storage-capacity of 333,400 acre-feet. It feeds two main channels, the Waranga-Rodney with a capacity of 250 cubic feet per second, and the Waranga-Campaspe-Loddon of 1000 cubic feet per second—reduced to 200 at its present termination, which is being extended to the west bank of the Loddon. The total length of distributary channels is 1650 miles. A second reservoir with a storage-capacity of 300,000 feet is being constructed at the junction of the Goulburn and Delatite rivers known as the Eildon or Sugarloaf site. There are smaller diversion and storage works on the Loddon, Werribee, Macallister, and Wimmera rivers, and gravitation and pumping schemes are in operation on the south bank of the Murray. Of the latter the most recent is that at Redcliffs, near Mildura, where an area of about 15,000 acres is being developed for the settlement of returned soldiers.

During 1923-24 the total area irrigated in Victoria was 324,558 acres, of which 94,479 acres were under lucerne 96,887 acres were irrigated for cereals and annual fodder crops, and 64,647 for vineyards, orchards and gardens, the balance for pastures, miscellaneous and fallow. In addition to the land irrigated there are large areas in the north-west (principally in the Wimmera and Mallee districts) which are supplied for domestic purposes and for stock use with water brought over long distances to fill settlers' excavated tanks. The total area of country lands within the State which were artificially supplied with water for this purpose during 1923-24 was 13,955,000 acres.

The royal commission appointed in 1884 by the government of *New South Wales* sat until 1887, and issued three reports. Little, however was done apart from constituting the municipal councils of Wentworth (1890), Hay (1892), and Balranald (1893) into irrigation trusts for the erection of pumping plants and the construction of distributary channels within their districts. In 1896 the colony took over all riparian rights, provision being made for the issue of licences to private irrigators. In the following year a distinguished Indian officer visited the colony on the invitation of the government to report on proposals for irrigation works, and selected the Murray and Murrumbidgee as the rivers on which irrigation projects were likely to prove most successful. A water and drainage act of 1902 provided *inter alia* for the expenditure of £1,000,000 within the next five years on the construction of hydraulic works, and an act of 1906 empowered the government to begin work on the Murrumbidgee scheme. This includes a concrete dam across the Murrumbidgee River at Burrinjuck with a maximum depth of storage of 200 feet and a capacity of 771,641 acre-feet; and a movable diversion weir across the Murrumbidgee at Berembed, 40 miles upstream from Narrandera, including a lock, sluiceway and 55 chanoine wickets, which can be lowered to pass freshets. The main canal with a capacity of 2000 cubic feet per second, takes off from the river immediately above the weir, and extends for a distance of over 90 miles to beyond the township of Griffith. There are numerous sub-



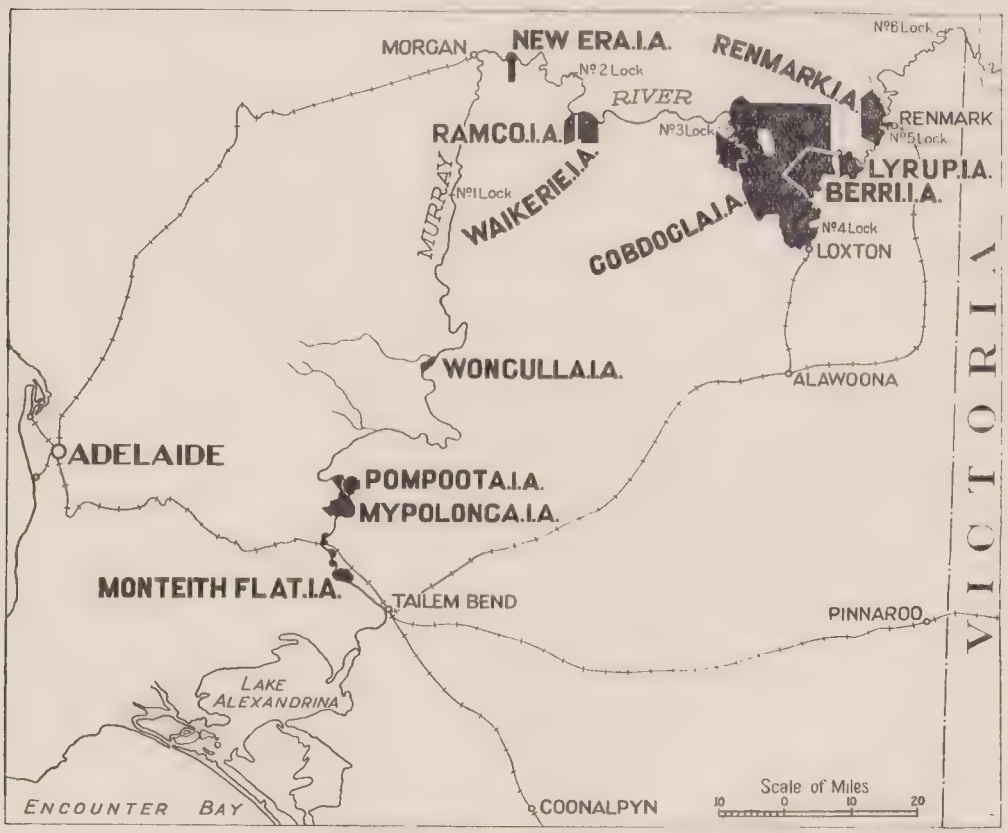
Murrumbidgee Irrigation Scheme.

sidiary canals for serving the irrigated areas, together with bridges and other structures, roadways to each farm, and a general surface drainage system. Butter, bacon and canning factories have been provided for treating the products of the areas, which are chiefly used for the growth of fruit and for dairying.

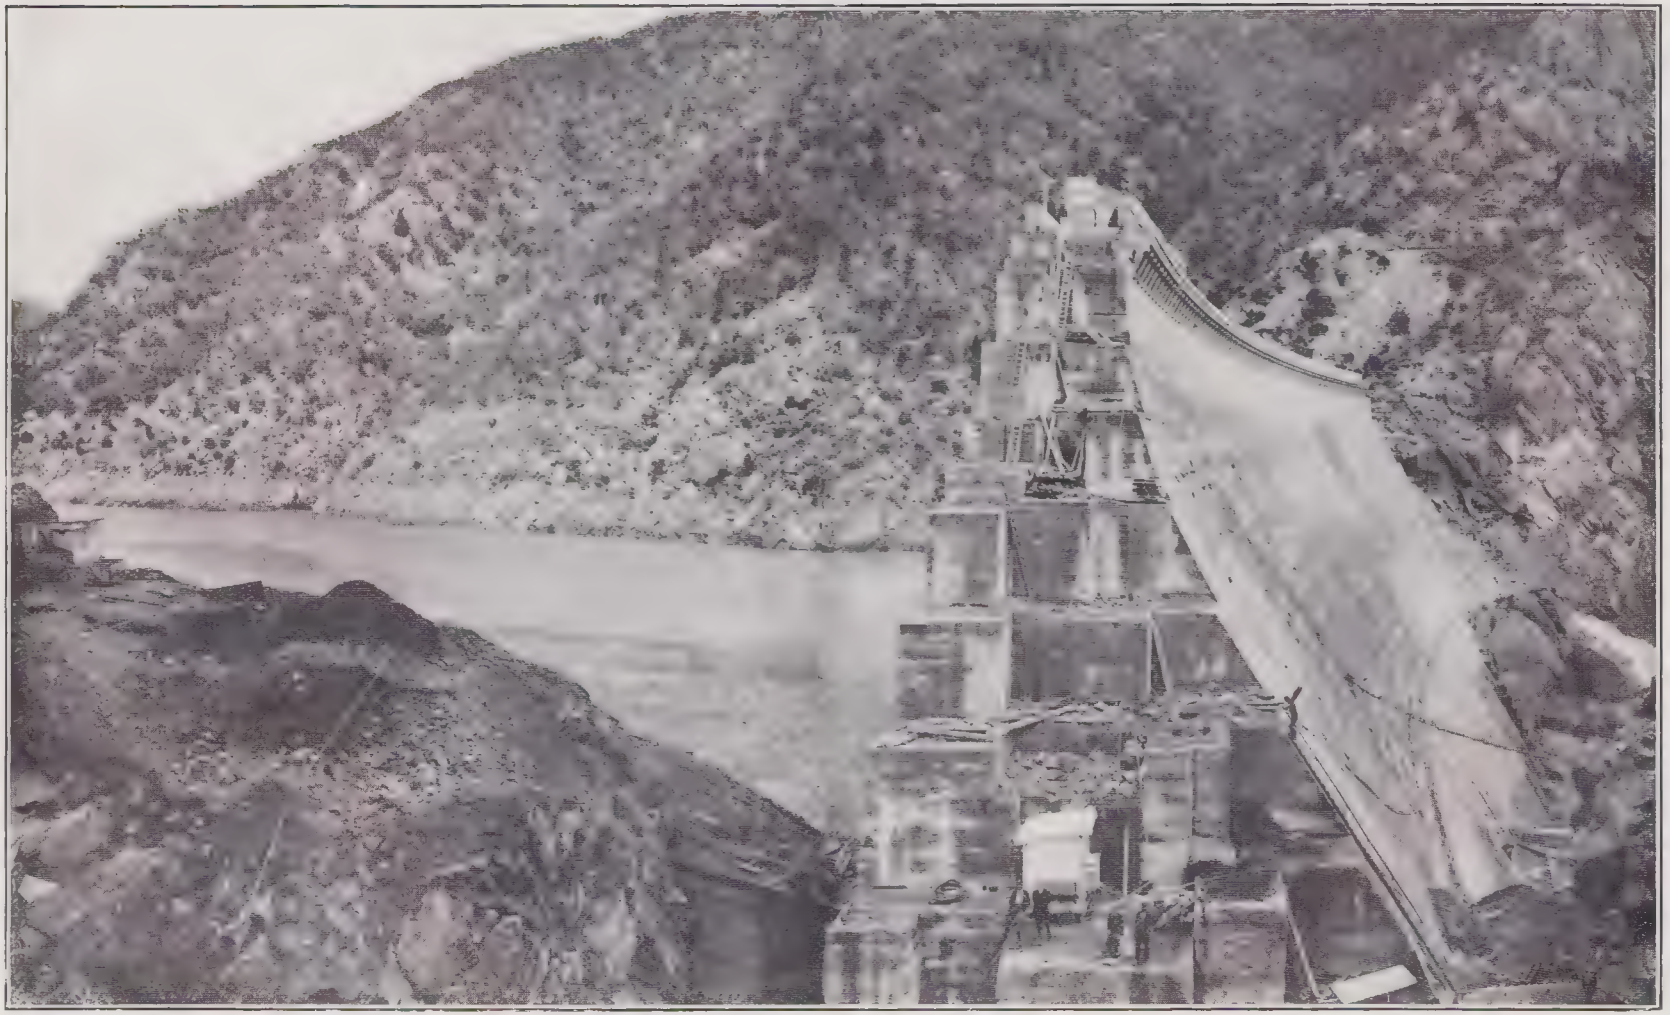
At the beginning of 1913 water conservation and irrigation works within the State were placed under a commission which controls, in addition to the Murrumbidgee scheme, small irrigation areas at Curlwaa, near Wentworth, and Hay, served by pumping from the Murray and Murrumbidgee rivers respectively. The Curlwaa machinery consists of a suction-gas plant, the combined capacity of the pumps being 12,500 gallons per minute. During the 1922-3 season 245,000,000 cubic feet of water were supplied. The length of the main channels is about 10 miles. The pumping machinery at Hay is of similar type, the capacity of the pumps being 4000 gallons per minute. During the 1922-3 season 172,906,732 cubic feet of water were pumped with nine pumpings. Work was commenced in 1924 for the development of a much larger area at Coomealla, adjacent to Curlwaa, water for which will be pumped from the Murray River; and investigation is being made of schemes for damming the Lachlan at Wyangala, the Macquarie at Burrendong, and the Hunter, Namoi, and Peel rivers at sites not yet determined, with a view of using the water for irrigation. The commission also controls the issue of licences to private irrigators, of whom a good many use pumped water on small areas for lucerne and other fodder crops, or for pastures and orchards. A 'private irrigation act' passed in 1924 is designed to foster private irrigation considerably, and more head storage works are needed to supply settlers in dry seasons. On 30 June 1924 1846 licences under the water act were current. Some private schemes utilize artesian water for irrigation purposes. At a small experimental farm at Pera bore (about eight miles west of Bourke) dates, olives, and oranges have been grown with great success in addition to fodder crops. Experimental work with artesian water has also been undertaken at Moree. The provisions of the water act which refer to the construction of storage-works for stock purposes by the State, and their subsequent control by trusts representing both the government and the ratepayers, are also administered by the commission.

Under the act trusts have been constituted for the supply of stock-water to some 2,955,000 acres by the construction of channels, weirs and other works, and to about 4½ million acres by artesian-bore drains. Works in connection with the trusts are carried out by the State, and the cost is repayable over a term of years. The administration is vested in trustees, usually three in each case, of whom one is a government officer; the other two are elected by ratepayers. Shallow boring for settlers is carried out by over 30 plants, operated by the commission, in districts covering 110,000 square miles.

In 1887, soon after the establishment of the Mildura settlement, the Chaffeys under an agreement with the government of *South Australia*



Irrigation areas, South Australia.



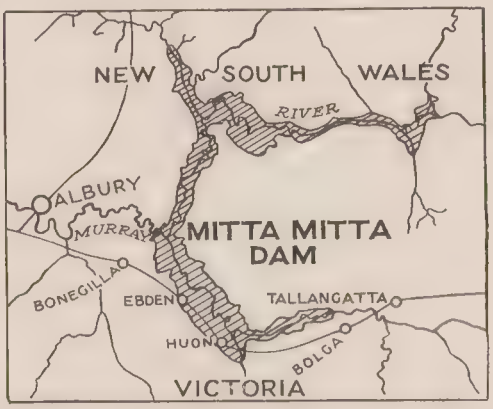
BURRINJUCK DAM UNDER CONSTRUCTION

began to irrigate the Renmark district on the north bank of the Murray 43 miles below the Victorian border. In 1893 the Renmark scheme was put under the control of a trust. There was little further development in irrigation in South Australia until 1910, when an irrigation and reclamation works department was created. Since that date several irrigation works have been constructed along the Murray above Morgan, the plant installed having a pumping capacity of 12,000,000 gallons per hour. Pumping and gravitation schemes have also been put into operation on the Murray below Morgan, the gravitation method being used to irrigate reclaimed swamp-land. These schemes supply an area of 5800 acres. Pumping plants have a total capacity of 5,000,000 gallons per hour.

Queensland possesses no snow-fed rivers, and is dependent on rainfall for irrigation. There is some irrigation from inland streams, but the only extensive schemes so far in operation are in the coastal district, where there is usually a heavy rainfall in the summer months, the rest of the year being dry. The most important works are those on the lower Burdekin River, where the waters both of the river and of the shallow wells along its banks are used. Subsurface water is available in abundance at depths of from 10 to 60 feet, and shallow wells lined with concrete cylinders are sunk to tap it, care being taken to avoid lowering the water-plane; pumping is done by electric power generated at a central station. Irrigation works have also been constructed at Townsville, Rockhampton, Bingera near Bundaberg (where the water is pumped from the Burnett River just above the head of tide-water), and Fairymead (where the water is pumped from a number of shallow spear-wells sunk on alluvial flats north of the Burnett River). In 1922 an area of 14,314 acres was irrigated in the northern State. Under the irrigation act of 1922 a commissioner of irrigation was appointed with wide powers. His chief work has been to develop the most ambitious scheme so far considered by the Queensland government, that for utilizing the waters of the Dawson River. An arched concrete dam, which is projected at Nathan's Gorge, will impound 2,500,000 acre-feet; the submerged area will be 83,177 acres. An area of 5000 acres at Castle Creek, 30 miles downstream, is being prepared for subdivision into farms of 10 to 25 acres each, but it is expected that eventually 200,000 acres will be irrigated for cultivation and as many more for stock and domestic purposes.

In *Western Australia* a number of private irrigation schemes are in operation on the south-western rivers, especially for fruit, fodder, and potato growing. The only works constructed by the government are those at Harvey, which were opened in 1916 to serve an area of 4000 acres. This scheme—which depends for its water supply upon a concrete dam about 40 feet high across the Harvey River, with a storage-capacity of 1600 acre-feet—is being extended.

An extensive scheme providing for conservation on the upper Murray and locking the river below Echuca is under construction; funds are provided by the government of the Commonwealth in association with the States of New South Wales, Victoria, and South Australia. When the Victorian government during the eighties adopted a progressive irrigation policy, South Australia feared that the proposals would affect navigation in the Murray, and in 1887 appointed a commission to investigate the subject. This was later merged into an inter-State commission, and negotiations were begun between New South Wales, Victoria, and South Australia (and later, the Commonwealth) for the conservation and distribution of the waters of the Murray and its tributaries. An agreement reached in 1914 was embodied in a River Murray Waters act, which was passed by the several legislatures and came into force on 31 January 1917. This act provides for the construction of the works by the State authorities under the control of the River Murray Commission, which includes representatives from each State and from the Commonwealth. The commission is responsible also for the gauging of streams and the distribution of waters. Provision has since been made for the construction of (1) the Hume or Mitta Mitta reservoir, and 17 weirs and locks



on the Murray River between Echuca and Wentworth; (2) nine weirs and locks on the Murrumbidgee River; (3) a storage scheme at Lake Victoria, and nine weirs and locks on the Murray below Wentworth. The Hume reservoir, situated above Albury at the junction of the Murray and Mitta Mitta rivers, was originally designed to have a storage-capacity of 1,100,000 acre-feet, but this will probably be increased.

H.H.D.

Irrigation Settlements. Irrigation works are now utilized chiefly for the development of 'closer settlement' policies. In *Victoria* there are 24 irrigation settlements which, with the exception of Mildura, are controlled by the rivers and water supply commission. Mildura is administered by the First Mildura Irrigation Trust, which was constituted in 1895. Holdings under the early settlement schemes varied from 400 to 600 acres, and were too large for intensive cultivation; it was estimated, for example, that only half the water available from the Goulburn works was utilized. About 1909, therefore, a policy of closer settlement on blocks of 12 to 80 acres was adopted, large estates being resumed and subdivided by the government for this purpose. Even after the adoption of this policy progress was slow, owing to the dual control of the closer settlement board and the water supply commission, and to meet this difficulty the management of all land in irrigation areas was in 1912 placed under the commission. Tenure within the settlements is freehold; land is sold to settlers at the valuation at which the estate was purchased while still unirrigated, plus the cost of development and transfer. Payment may be made in instalments extending over a period of 31 years, with interest at 4½ per cent.

The government may make advances to settlers for necessary development work. The settlers are not burdened with the cost of the main construction works, which are financed by the State. The Goulburn-Loddon settlements produce both fodder and fruit crops. In 1921-2 the Shepparton Co-operative Canning Factory produced 214,000 dozen cans of fruit, the supply of fruit increasing at such a rate that other co-operative companies were formed at Ardmona and Tongala to cope with it. Mildura covers an area of 45,000 acres, of which 13,000 were under intense cultivation in 1922-3; the number of water-acres supplied during the year was 42,807. The country, which before the construction of the irrigation works was barren—carrying only one sheep to 30 acres—has proved itself suitable for the growing of vines (especially sultanas), citrus and other fruits. In 1920 the dried fruit harvested from 13,000 acres was valued at £1,238,373 gross.

In *New South Wales* the most important irrigation settlements are those established in connection with the Murrumbidgee scheme in the districts of Yanco and Mirrool. The township of Yanco is Leeton, 12 miles north of Narrandera; Griffith, about 30 miles north-west of Leeton, is the headquarters of Mirrool. The conditions for the disposal of irrigation blocks in these areas are laid down in the crown lands consolidation act of 1913 and the crown land and irrigation (amendment) act of 1914. The tenure is perpetual leasehold; the blocks vary in size from two acres to over 200, the smaller holdings being used for intense cultivation and the larger for dairying. A large area of land in both settlements was reserved for returned soldiers. Each irrigable block carries a certain number of statutory water-rights—a water-right being defined as the right to the amount of water that would cover an area of one acre 12 inches deep. Advances for necessary improvements and for the purchase of stock may be made to settlers by the government on easy terms; the payment by any settler of sums due for rent, water-rates, or improvements effected by the crown may be suspended for any period or periods not exceeding four years, payment to be made in instalments over a period not exceeding 46 years. To provide a local market for settlement products the controlling commission established butter, bacon, vegetable, fruit-canning, and cheese factories in the district; a government experimental farm was opened at Yanco, and nurseries for the propagation of trees and vines to supply settlers' wants were established; sufficient vines are now produced to supply vignerons throughout the State. A power-station has also been erected for the distribution of electric light and power to townships and farms. Despite these advantages the settlements are not yet on a satisfactory financial basis. It is the policy of the government to encourage settlers to take over these industrial plants on a co-operative basis, and in most cases this is already accomplished. Commission control has also been modified by the constitution of an advisory board, on which sit elected representatives of the settlers. On 30 June 1923 2064 farms were held, representing a total area of 119,609 acres; approximately 8036 acres were under deciduous fruit-trees, 5033 under citrus fruits, and 5641 under vines. The number of town blocks held was 839, and the estimated population of the settlements was 12,000. The settlements at Curlwaa and Hay are on a smaller scale. On 30 June 1923 the Curlwaa area covered 10,600 acres, divided into irrigable and non-irrigable holdings; of the irrigable area 1117 acres were planted as orchards or vineyards, of which 868 acres were in full bearing, and there was a small area under lucerne. The estimated weight of dried fruits produced at Curlwaa in 1922-3 was 12,187 cwt., the principal yields being sultanas (3588 cwt.), peaches (2800 cwt.), and currants (2625 cwt.). The Hay irrigation area on 30 June 1923 covered 4500 acres, of which 1035 acres, divided into blocks of from 3 to 34 acres, was used for irrigation. There is not much fruit-growing in the district, dairying being the principal industry. Land in the Curlwaa and Hay areas may be leased for periods not exceeding 30 years. Each lessee is entitled to receive a quantity of water equivalent to a depth of 30 inches per annum over his area, of which not more than four inches may be used in any one month. Since 1913 both areas have been under the control of the water conservation and irrigation commission.

In *South Australia* the principal settlement, that at Renmark, is controlled by a trust constituted in 1893; it covers an area of 30,000 acres, of which 7850 acres are irrigated. The population of the town and settlement is 4800. Fruit-growing is the principal industry. There are two distilleries for the manufacture of grape-spirit, and several packing sheds for dried fruit, the pack of which in 1923 amounted to 2750 tons. The other settlements on the Murray, both above and below Morgan, are administered by the irrigation and reclamation department. Those above Morgan covered, in February 1924, an irrigable area of 17,827 acres allotted to 1068 settlers, 1280 acres being reserved by the department for fodder crops. The soil—for the most part a red, sandy loam—is chiefly suitable for fruit and vine culture. The settlements on the lower Murray comprised 5800 acres of high, irrigable, and reclaimed swamp-land, suitable for fruit and fodder crops. There are 241 settlers in this area. The disposal of land, which is governed by the irrigation and reclaimed lands act of 1914, is on a perpetual leasehold basis, the rentals being fixed by the irrigation commission. The maximum area of irrigable or reclaimed land one person may hold is 50 acres; residence for nine months in the year is compulsory, and certain improvements must be carried out by the settler. Land above the irrigating channels is also offered to lessees of irrigable blocks on a perpetual leasehold basis for dry-farming, grazing, etc. The government is authorized to make advances to settlers for necessary improvements on easy terms.

In *Queensland* and *Western Australia* irrigation settlements are on a small scale. W.S.C.

Irvine, Sir William Hill, nephew of John Mitchel who founded the *United Irishman,* was born at Newry in Ireland on 6 July 1858 and educated at Trinity College, Dublin (B.A., 1879; LL.D., 1904), and in 1879 migrated to Victoria to teach at Geelong College, at the same time studying at the university of Melbourne (M.A., 1882; LL.M., 1886). In 1884 he was called to the Victorian bar, and in 1894 entered politics as representative of Lowan in the assembly; this seat he held till 1906, when he left State for federal politics. When McLean defeated George Turner in 1899, Irvine joined his ministry as attorney-general (to 19 November 1900), and in 1902 on the defeat of Alexander Peacock formed a ministry of many internal changes in which he combined with the

premiership first the post of attorney-general (10 June 1902 to 20 July 1903), then that of solicitor-general (6 February to 18 August 1903), and then that of treasurer (21 July 1903 to 18 February 1904). His most forceful colleague was Thomas Bent (q.v.), with whose aid he succeeded in quelling a dangerous railway strike in 1902-3; in doing so he discovered that civil servants could exercise great pressure on their representatives in parliament, and as a temporary remedy he carried an act disfranchising the public service as far as the ordinary constituencies were concerned, and giving it members of its own. Early in 1904, weary of partisan politics and at variance with many supporters on the land question, he gave place to Bent and became a private member. In 1906 he entered the federal lower house as member for Flinders, which seat he held until he left politics altogether. In this house he kept aloof from the principal parties, being regarded as an independent critic and the spokesman rather than the leader of a cross-bench section. In 1913, however, when Joseph Cook succeeded the Labour leader Andrew Fisher with a bare majority behnid him, Irvine accepted the attorney-generalship, mainly in order to shape and carry certain constitutional amendments; but the war, and the defeat of Cook at the polls in 1914, prevented any move in this direction, and Irvine resumed his independence. On 5 April 1918 he left politics to become lieutenant-governor and chief justice of Victoria. (K.C.M.G., 1914.)

Irwin, FREDERICK CHIDLEY, joined the army in 1808 (ensign, 1808; lieutenant, 1809; major, 1836; lieutenant-colonel, 1845), but nothing is known of his career until in 1829 he was sent to Western Australia in command of a detachment of the 63rd regiment, which had been allotted for the protection of the newly established Swan River settlement. In 1831 he became senior member of the legislative council, and from September 1832 to September 1833 administered the government during the absence of Captain Stirling. He then returned to England and in 1835 published what was probably the earliest account of the colony—*The State and Position of Western Australia*; he also took an important part in the foundation of the Western Australian Association. In 1836 he was sent back to Western Australia with the rank of major to command the local garrison, and from February 1847 to August 1848 was governor of the colony. The Irwin River was named after him by George Grey. (K.H., 1842.) J.S.B.

Isaacs, ISAAC ALFRED, born in Melbourne on 6 August 1855 and educated at the Beechworth grammar school and at the university of Melbourne (LL.M., 1880), was called to the Victorian bar in 1880. Rapidly successful in his profession (he became Q.C. in 1899), he in the early nineties began to interest himself in politics, and in 1892 was returned to the legislative assembly as representative of the Bogong electorate. He was solicitor-general in the Patterson ministry of 1893-94, and attorney-general in the first (1894-99) and second (1900-1901) Turner ministries; then, leaving State for federal politics, he was elected by Indi (Victoria) to the house of representatives, and soon became prominent among the radical protectionist section of Sir E. Barton's followers. In 1904 the Deakin ministry was ousted in favour of J. C. Watson's Labour ministry, and it was doubtful whether Deakin's followers would coalesce with Watson's or with Reid's, but Isaacs collaborated with Lyne in preventing the eventual coalition with Reid's from becoming complete; Deakin could carry over only 15 followers, and Lyne and Isaacs with eight others shared the opposition benches with Labour. When in June 1905 Deakin withdrew his support from the Reid ministry and in July formed a new one, Isaacs was the obvious candidate for the attorney-generalship, which he held until in October 1906 he was elevated to the high court bench. His career as a judge has been marked by special attention to constitutional questions, on which he adopts an attitude strongly favourable to the extension of the Commonwealth's powers.

Island Snapper. See EMPEROR BREAMS.

Isoëtaceae. See LYCOPODIALES.

Isopogon, a genus of the family Proteaceae, consisting of shrubs with rigid, entire or much-divided leaves, endemic in extra-tropical Australia; most of the species are confined to Western Australia. The flowers are yellow, pink, or lilac, crowded in dense cylindrical formation round a woolly axis; corolla regular, with slender tube—the upper portion falls off entire, the persistent base eventually splitting up into segments from the pressure of the ripening fruit; style slender, more or less dilated and clothed with hairs; fruit a hairy nut, embedded in the cone scales and falling with them.

Isopogon anemonifolia.

Isoptera, an order of insects which includes the so-called 'white ants' (see TERMITES) and the web-spinners (embids). Both these families have two pairs of wings—equal or sub-equal—inserted far apart upon the thorax, and with closely similar venation; in both groups, also, the structure of the mouth-parts is normally mandibulate, and the antennae are of a primitive, many-jointed type. But in other respects the groups exhibit very different specializations, the white ants in their social systems and castes, the web-spinners in the habit which gives them their name. It is not yet settled that they are

really close relatives, and they should be regarded as at least two quite distinct sub-orders, Termitoidea and Embidoidea—the first showing, through the gigantic *Mastotermes*, evidence of original descent from blattoid ancestors of a very primitive type.

Termites are discussed under their own name. Web-spinners are rare in Australia, as elsewhere. Only four species have been described, all being placed in the genus *Oligotoma*. Other species exist in collections. They are active, sensitive insects, not unlike an elongated termite in appearance, but much more alert. They run so quickly that it is almost impossible to hold them on one's hand. They are very sensitive to the state of the atmosphere, and cannot even exist unless the exactly right amount of moisture is present. The web, which is usually found on the ground, under loose rocks, stones, or logs, is spun from glands placed in the enlarged metatarsi of the fore-legs.

Froggatt has discussed the embids in *Proceedings* of the Linnean Society of New South Wales, 1896-7, 1904-5. R.J.T.

Jabiru. See IBISES.

Jacana. See WADERS.

Jack, ROBERT LOGAN (1845-1921), born at Irvine in Ayrshire on 15 September 1845 and educated at the university of Edinburgh, was in 1866 appointed assistant geologist on the Scottish geological survey, and in 1877 transferred to Queensland as government geologist, with headquarters at Townsville. In 1879 he commenced a series of expeditions which, originally intended to open up new goldfields, traversed and described geologically a great part of the Cape York Peninsula. The first (1879) penetrated from Cooktown to the Archer River, opening a new route to goldfields on the Coen which had been previously exploited and abandoned. The second (1879-80) traversed the peninsula from the Archer to Cape York, encountering hostile blacks several times on the way. For the following 20 years Jack made both scientific and practical use of his position, helping to develop the mining industry and extend the system of artesian wells; he published pamphlets and books on both subjects, and in conjunction with R. Etheridge brought out in 1892 a *Geology and Palaeontology of Queensland and New Guinea.* Resigning his post in 1899, he led an expedition to Korea and northern China, but was thwarted in 1901 by the outbreak of the Boxer war; this produced another book. *The Back-blocks of China,* published in London in 1904. That year he returned to Australia and settled down as a consulting geologist, being frequently employed by the government of Western Australia to investigate mining and artesian problems. The university of Glasgow for his services to science made him an honorary LL.D. His last achievement was *Northmost Australia,* a very full and studied account of exploration since 1600 in the region north of the tropic of Capricorn. While this book was being published in London, its author died at Sydney on 5 November 1921.

Jackman, WILLIAM, born at Dittisham near Dartmouth in England on 19 December 1821, seems to have spent his early boyhood aboard coasters plying in the Channel, but on 17 August 1835 embarked in the *John Barry* for Sydney. According to his own account (the accuracy of which is discussed below) the vessel reached Port Jackson on 29 November, 102 days out from London—a very short passage for those times—then went off to Port Phillip with passengers, and there made ready for a voyage to Bombay. Jackman promptly deserted, shipped aboard the government brig *Siren,* and on 17 January 1836 went in her to Launceston in company with some troops. After various adventures in Tasmania he on 28 April 1837 shipped at Launceston in the whaler *Carib,* which was wrecked about three months later in Nuyts' Archipelago, towards the eastern end of the Australian Bight. Most of the crew succeeded in reaching the shore on floating wreckage, and in securing food and materials for boat-building from the stranded ship; the castaways divided themselves into parties, some to work at constructing a boat, others to search the beach for shellfish and for debris from the wreck. Jackman, when alone on a part of the shore remote from his comrades, was one day surrounded by blacks, who marched him off to the interior, and there he remained for about 20 months, becoming to all intents a member of the tribe. On 28 March 1839, when the tribe was once more on the coast, the whaler *Camilla* of Hobart luckily put in to wood and water; one of her boats came close enough for Jackman to attract notice, and he succeeded in escaping, ultimately making his way to England via King George's Sound, Canton, and South America. His long account of his life among the blacks was embodied in *The Australian Captive; or, An Authentic Narrative of Fifteen Years in the Life of William Jackman,* edited by I. Chamberlayne and published in London in 1853. Chamberlayne, who was a clergyman at Lyndonville in New York State, U.S.A., refused to endorse the statements in the book, which were made on Jackman's sole authority; on the other hand he believed that Jackman's story was entitled to credit. It is difficult to verify any considerable part of the story; but the first part is certainly incorrect. The *John Barry* did not leave England until 9 September 1835 at earliest, for despatches of that date were sent by her. She did not reach Port Jackson in November; indeed, the despatches sent by her were not acknowledged by Bourke until 10 May 1836. Further, in January 1836 she would not have been allowed to carry passengers from Sydney to Port Phillip, and would not have chosen Port Phillip as a starting-point for Bombay. Again, the *Siren* was not a government brig, but a small trader of 141 tons burthen plying between Sydney and Hobart, and in January 1836 was lying in Port Jackson, which she left on the 21st for Hobart. Many of the details Jackman gives about his adventures in Tasmania are also demonstrably incorrect—e.g. he describes Launceston as in southern Tasmania. Of the *Carib* there is no other record in those years, and she certainly did not sail from any Tasmanian port in 1837. As for Jackman's life among the blacks, his account of it is completely at variance with everything known of Australian aborigines; the weapons, marriage customs, methods of training youths, etc., described by him prove his utter ignorance, and make it impossible to believe a word he says about anything else. His actual knowledge of Australia seems confined to the names of a few Tasmanian settlements and of one official—whom he misdescribes.

Jackson, Sir George. See DUCKETT, SIR GEORGE.

Jacksonia, a genus of the family Leguminosae, endemic in Australia, consisting of shrubs with cylindrical, angular, or winged stems and branches. The leaves in most species are replaced by minute scales; pods oval, flat, or swollen. *J. scoparia* (Dogwood, owing to its offensive odour when burning) is a graceful shrub, or small tree, with many pendulous, greyish-green branches along which the yellow flowers with their silvery calyces are produced in great profusion. In parts of Western Australia it provides a useful fodder, relished by cattle and horses. The timber is dark brown, and takes a good polish, but is rather small for most purposes.

Jacky Winter. See FLYCATCHERS.

James, SIR WALTER HARTWELL, born on 28 March 1863 in Perth, Western Australia, was called to the local bar in 1888, and became K.C. in 1902. In June 1894 he was elected to the legislative assembly as member for East Perth, in 1897-8 was one of the delegates from his colony to the federal convention, and in July 1902 became premier and attorney-general of the State. When his ministry was defeated in August 1904, he took the agent-generalship in London, and held it until 1906. Since that time he has lived in Perth. (Kt. Bach., 1907.)

Jamison, SIR JOHN (1776 1844), son of Thomas Jamison who was surgeon's first mate in H.M.S. *Sirius* and afterwards (1802-9) surgeon-general of the colony, was born in 1776, educated for the medical profession, and appointed surgeon in the navy. While serving in the Baltic in 1807, he was decorated with the order of Gustavus Vasa by Charles XIII of Sweden for his aid during an outbreak of cholera in the Swedish army; hence the title 'Sir,' which was thenceforth given him, was not really valid in British possessions. When his father died on 27 January 1811, he inherited a good deal of property in New South Wales, and migrated to the colony to take it over, reaching Sydney on 28 July 1814. Almost immediately he demanded an additional grant of land, on the ground that his inherited estate at Regentville near Penrith was too small for his stock; Macquarie, though he refused the grant, held him in favour, and took him on the journey to Bathurst over Cox's new road in 1815. In 1817, however, something happened. On 29 March of that year Macquarie included him in a list of citizens 'truly and liberally interested for the public benefit;' on 1 December this description was altered to 'intriguing and discontented.' By 1819 the trouble was over, and Jamison was again one of the 'loyal, intelligent and respectable' inhabitants of the colony. His relations with Brisbane were similarly troubled, the governor at first recommending him for a seat on the council and then withdrawing his recommendation; and in 1826 Darling was strictly forbidden by Bathurst to give him any civil employment, a prohibition repeated by Huskisson in the following year. It was not until 1837 that he became a member of council, the appointment ceasing with the proclamation of a new constitution in 1843; and he died at Regentville on 29 June 1844.

His connection with the public life of the colony was thus intermittent and not very important. It was as an agriculturist and squatter that he did valuable work, which was publicly recognized by the grant in 1829 of the gold medal of the London Society for the Encouragement of Art and Manufacture. He was also a good racing man, founder and president of the Sydney Turf Club (1825-7) and the Australian Racing and Jockey Club (1828 onwards). Jamieson-street in Sydney is named after him, though a wrong spelling has been allowed to creep in. On his estate at Regentville Henry Parkes was a labourer in 1839-40 and Thomas Bent was born in 1838.

Jarrah. See EUCALYPTUS.

Javelin-fish, a tropical fish (*Pomadasys hasta*) plentiful on the northern coast of Australia, and occasionally ranging southwards to the New South Wales border. It attains a length of two feet, and is regarded as a first-rate food-fish. One of the spines of the anal fin is enlarged to form a stout spike, from which the fish takes its popular name. A number of allied species occur in Queensland waters, but little has been recorded of their habits. Sweet-lips (q.v.) are near relatives. A.R.McC.

Jefferis, JAMES (1833-1917), born at Bristol on 4 April 1833, was educated at the university of London (B.A., and LL.B.) and received his theological training at New College, London. His first charge was at Saltaire near Bradford in Yorkshire. Leaving England on account of his health, he arrived in South Australia in 1859, and held services in the temperance hall, North Adelaide. On 15 August 1859 a public meeting held in this hall resolved 'to take measures without delay to secure the erection of the intended Congregational church;' the movement resulted in the erection of the Brougham Place church, which with adjuncts is estimated to have cost from £16,000 to £18,000. Here Jefferis found a sphere adequate to his powers, and would not be drawn away from it, though about two years after its opening he was invited to the pastorate of the Pitt-street church in Sydney. His was a ministry of the robust, positive, progressive type; young men rallied round him in large numbers, and the Young Men's Society which he formed took the leading place among such organizations. For 18 years he held a position of commanding influence in Adelaide, both as preacher and as publicist. He was professor of mathematics and natural science in Union College, an institution founded in 1872 to provide advanced education and theological training, and backed by Baptists, Congregationalists, Presbyterians, and, later, Bible Christians. In 1872 Walter Watson Hughes (q.v.) offered to present the college with £20,000, but at Jefferis's suggestion the money was diverted to assist in the establishment of a university. On the establishment of the university Jefferis was offered a professorial chair (which he refused) and chosen as a member of the senate.

In 1877 he left Adelaide for Sydney to become the pastor of the Pitt-street church, to which he had been called three times. For 13 years Jefferis held a commanding position in Sydney, his influence extending far beyond that city and outside his own denomination. He was an ardent defender of national (as opposed to denominational) education, and through his exertions the income from the clergy and school lands, valued at £2,500,000, granted in the time of George IV, was diverted from religious purposes to public education. In December 1889 Jefferis left Australia for England, where in 1890-94 he held pastorates at New College Chapel in St. John's Wood and at Torquay.

Soon, however, the work in Australia appealed to him again, and in May 1895 he returned to his former sphere in North Adelaide, served faithfully and successfully for six years more, and retired on 6 March 1901. Then followed 16 years of retirement from active ministerial life, but not from the service of his brethren, his denomination or the public weal. He died at Encounter Bay on 25 December 1917.

Among his services to Australia must be mentioned his ardent advocacy of the cause of federation.

F.V.P.

Jelly-fish, the popular name of several genera of Scyphozoa, a class of Coelenterata comprising medusae with endodermal gonads, and with a gullet and vertical partitions in the enteron of the polyp stage (when this exists). The commonest form on our coasts is *Aurelia*, whose convex surface is marked by four conspicuous horseshoe-shaped purple bands. In living specimens of *Aurelia* the umbrella is sharply curved, and its margin is fringed with innumerable tentacles, very short and fine. The uniformity of this fringe is broken by eight notches, each containing a sense organ. The 'handle' of the umbrella (manubrium) is divided into four somewhat short arms, having the mouth in the centre. In its life-history *Aurelia* passes through a complicated series of changes. The fertilized egg develops into a hollow, oval embryo, which settles down and becomes a small polyp with a mouth, stomach, and tentacles; this phase was formerly supposed to be a distinct individual, and was named 'hydra-tube' or 'trumpet polypus.' It is usually not more than one-eighth of an inch in height, and is to be found far out on the rocks. In the course of time the little hydra-tube elongates, and becomes marked by a series of transverse lines, so that it appears like a pile of saucers. A little later the top saucer floats off, turns over, and becomes a little jelly-fish which grows rapidly and becomes an *Aurelia*. The same thing occurs with the lower saucers, so that the single hydra-tube gives rise to a number of large jelly-fishes.

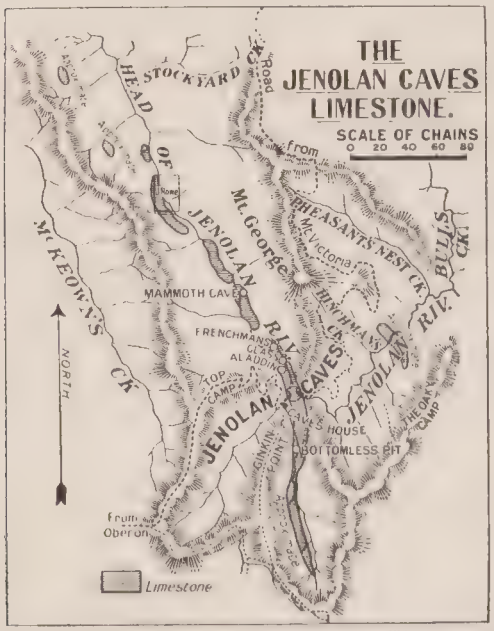
Some of the jelly-fishes in Australian waters are peculiar in having the large lips fused over the mouth, so as to almost obliterate the opening, which is reduced to a number of minute apertures capable of taking in only the tiniest food-particles. These are large, handsome forms; their deep bell may attain a diameter of two feet, and is not provided with marginal tentacles. Another large jelly-fish is *Crambessa*, found in the landlocked harbours along the coast of New South Wales; this form frequently occurs in large numbers (probably brought together by currents and tidal action) but at other times is widely scattered. At all times it forms a very characteristic feature of the life of our coastal inlets. Two colour-varieties of this jelly-fish can be recognized, one blue and transparent, the other deep yellowish-brown and not transparent.

E.A.B.

Jennings, Sir Patrick Alfred (1831-1897), born at Newry in Ireland on 20 March 1831 and educated at the Exeter high school, renounced law for engineering and that for a commercial life, but in 1852 migrated to Victoria, worked on the goldfields, and in 1855 settled at St. Arnaud, where he put up quartz-crushing machinery on a large scale. Prosperity helped him to buy Warbreecan station near Deniliquin in the Riverina district of New South Wales, and he was for a time identified with a proposal to make that district a new colony under the name 'Albertland.' He had long before this attempted to enter politics as representative of a Victorian constituency that stretched from the Pyrenees to the Murray, but got what he afterwards described as 'the most thorough drubbing a young candidate ever received.' In 1867, however, James Martin nominated him to the New South Wales council, and at the end of 1869 he was elected to the assembly as member for the Murray; this seat he resigned on 25 June 1872, hoping but failing to secure election for Mudgee. For the next eight years he lived at home or travelled, representing his colony at the Melbourne exhibition of 1875 and the American Centennial exhibition of 1876. In 1879 he was executive commissioner of the Sydney international exhibition. But he never lost interest in politics; Robertson in 1878 offered him the leadership of the council in a ministry that was never formed, and in November 1880 he came back to the assembly as member for the Bogan. When the Parkes-Robertson coalition broke up at the end of 1882, Jennings joined the Stuart ministry as vice-president of the executive council, but held office for seven months only; for two months at the end of 1885 he was colonial secretary under George Dibbs, and on 26 February 1886 (the intervening time having been filled by a scratch ministry under John Robertson) formed a ministry himself from both sides of the house, whose career was chiefly remarkable for its attempt to introduce a land tax. Its composition was too discordant to allow of long life, and on 19 January 1887 Jennings resigned. Parkes, who succeeded him, sent him to London to represent the colony at the colonial conference of 1887. Never a strong party man, he now dropped out of active politics, though Parkes put him back in the council in 1890, and that body elected him one of its representatives at the federal convention of 1891. Thenceforward he lived in retirement, and died at Brisbane on 11 July 1897.

Outside politics (where his career was troubled, though everyone liked him) Jennings was a cultured and amiable citizen, a member of the university senate, a trustee of the national art gallery, and a zealous patron of music. In 1874 he received from Pius IX the order of St. Gregory the Great. (C.M.G., 1879; K.C.M.G., 1880.)

Jenolan Caves, a series of caves excavated by water in a stratum of Silurian limestone about 500 feet thick that helps to form the core of the main range behind Port Jackson. At a point about 60 miles due west of Sydney this stratum has been exposed by the valleys of two converging streams which, instead of cutting through it as they have through the neighbouring claystones, burrowed into it by dissolving away the lime along natural fissures, and so created (*a*) a series of narrow channels with occasional chambers, (*b*) two large cavernous thoroughfares, one a low tunnel through a superincumbent hill, the other an enormous cavity in which the tower of the Sydney post-office could stand upright. The now insignificant Camp Creek, coming from the south-west, thus in flood-time penetrates the Grand Arch, and below it joins the Jenolan River, a longer stream that has eroded a wider valley and passes in flood-time through the huge cavern known as the Devil's Coach-house. In ordinary seasons both these streams are subterranean, Camp Creek disappearing just above the Arch, Jenolan River a



mile or two above the Coach-house. The caves proper occur in three groups, one (Lucas and River) south of the Arch, a second (Imperial, Elder and Nettle-and-Arch) in the main limestone block between the Arch and the Coach-house, and a third (including Aladdin, Bow and several not yet properly explored) along the sides of the Jenolan River valley.

The problem of the origin of such caves is dealt with under LIMESTONE CAVES. The history of their discovery is, according to the accepted version, as follows. In 1835-8 a convict escapee, McKeown by name (it is also spelt McEwen), used to levy blackmail on settlers in the area round Oberon, killing their stock and holding up their teams—usually by stealing the ox-bows—unless he was bribed off. After many attempts a settler, Charles Whalan, in 1838 managed to track him into the very heart of the main range and along a gully on its eastern side, in which his hut was found and he himself captured in it. His captors, finding themselves in a pleasant and possibly fertile valley, followed the stream down until they entered the huge cavern afterwards called the Coach-house. Other discoveries followed slowly, including those of the Elder (1848) and Lucas (1858) caves—the latter named after John Lucas, who in 1864-9 represented Hartley in the legislative assembly. On 2 October 1866 an area of 6¼ square miles surrounding the caves was made a government reserve; on 8 March 1867 Jeremiah Wilson, a settler from Oberon who had spent a good deal of time in cave-exploration, was made caretaker and chief guide. The reserve now became a tourist resort; but, as it could only be reached through Oberon—which was itself over 140 miles from Sydney and 20 miles from the caves—tourists were scarce, except from the western districts. In 1896, however, the government completed a more direct road from Hartley in the Vale of Clwydd, by which the caves are only 36 miles from the Blue Mountains tourist centre of Mount Victoria (77 miles from Sydney); and this shortening of the distance, coupled with the establishment of a government hotel in the valley above the Arch, at once made Jenolan one of the principal tourist resorts of New South Wales.

The aboriginal name for the caves was Binomea, but for 50 years after their discovery they were known as the 'Fish River' caves, since they had been approached from the valley of the Fish River, which is a tributary of the Macquarie flowing past Oberon. In the tangle of gullies thereabouts it was easy to mistake the direction in which the water of the two creeks flowed; so in course of time men went astray in the lower gully, followed it down in the expectation of coming to settlements on the Fish River, and found themselves after long wanderings in the uninhabited valley of the Cox. It was therefore decided to alter the official name, so that the mistake should not be repeated; and on 10 August 1884 the caves were officially named after the parish of Jenolan, at the northern end of which they are situated.

Jequirity Beans. See ABRUS.

Jersey, EARL OF. Victor Albert George Child Villiers (1845-1915), 7th earl of Jersey, born on 20 March 1845 and educated at Eton and at Balliol College, Oxford, succeeded his father as earl in 1859, in 1875-7 was a lord-in-waiting to Queen Victoria, and in 1889-90 was paymaster-general in the Salisbury ministry. In the latter year, on 26 July, he was gazetted governor of New South Wales in succession to Lord Carrington, during whose term of office the governorship had become a social rather than a political function; and the new governor's sound judgment was of great value to ministers and others during the years which witnessed the first federal convention, the advent of the Labour party to parliament, the great strike at Broken Hill and the beginnings of a severe financial crisis. On 2 March 1893 he resigned office and returned to England, where in 1896-1905 he was chairman of the light railway commission. Though he never again held any office connected with Australia, his interest in the country was permanent and, whenever needed, active; during the first years of the Commonwealth he readily performed many unofficial duties that should have been done by a high commissioner, and his influence with the foreign office was again and again successfully placed at the disposal of the federal authorities. He died on 31 May 1915. (G.C.M.G., 1890; G.C.B., 1900.)

Jervois, SIR WILLIAM FRANCIS DRUMMOND (1821-1897), born at Cowes in the Isle of Wight on 10 September 1821, and educated at the royal military academy, Woolwich, was commissioned 2nd lieutenant in the royal engineers on 19 March 1839 (lieutenant, 1841; captain, 1847; brevet-major, 1854; lieutenant-colonel, 1861; colonel, 1872; major-general, 1877; lieutenant-general 1882). On 26 March 1841 he was ordered to South Africa, where for the next eight years he carried out important engineering and survey work in connection with the defence of the Cape Colony against Kaffirs and Boers, and with the Kaffir war of 1846-8. His survey of British Kaffraria was, 30 years latter, the most accurate available to Lord Chelmsford. Returning to England in 1849, Jervois was from 1852 to 1855 employed on the construction of fortifications in the Channel Islands, and in 1855 was given the command of engineers in the London district; on 7 April 1856 he was attached to the war office as assistant inspector-general of fortifications. The next

year he became secretary to the defence committee, and prepared plans for the defence of London in case of invasion; in 1859, as secretary to a royal commission on the defences of the United Kingdom, he drafted a scheme which was adopted by parliament in 1860 and carried out at an expense of £7,500,000; in 1862 he was put in charge of all British defences as director of works and fortifications, and became the confidential adviser of successive secretaries of state for war. In 1863-5 he visited Canada three times to report on the defences of the British colonies in North America, and to lay out a scheme of defence for their protection; he paid similar visits to Halifax, Bermuda, Gibraltar, and Malta (1869), Aden, Perim, and the chief Indian seaports (1871-2), and, after supervising the completion of his 1859 defence scheme, was in 1875 made governor of the Straits Settlements. Having suppressed a dangerous outbreak in Perak and devised defences for Singapore, he was in April 1877 appointed to advise the Australian governments on the defence of their seaports, taking in October the governorship of South Australia; the comparative leisure of the latter position enabled him to spend a good deal of time in inspecting and planning fortifications for nearly all the important harbours from Adelaide to Brisbane. The scheme on which he worked was designed to provide (*a*) a series of harbours protected with batteries commanding their approaches, (*b*) a small, well-equipped land force to repel landings outside these harbours; but he proposed that raiders should, if possible, be met at some distance from the coast by warships owned by the separate colonies and based on the protected harbours. This proposal was unwelcome at the time, since colonists of those days considered the naval defence of Australia to be purely a matter for the British government; but it initiated discussions that ended in the Tryon agreement of 1886, and heralded a genuinely Australian navy. Transferred in January 1883 to New Zealand (on whose defence he had given advice as far back as 1871), he made his term of office memorable by devising defences for the four chief ports, which were completed before he left the colony, by lecturing on defence subjects up and down both islands, and by persuading the New Zealand government to adopt at once the proposals made by Admiral Tryon (q.v.) for the naval defence of Australasia. In 1885 he saved the colony from a serious entanglement in European complications by tactfully thwarting his ministers' intention to annex the Samoan group. In matters outside defence he did not altogether keep in touch with local feeling; thus, while in South Australia, he did his best to prevent the prohibition of Chinese immigration, advocated unofficially the division of northern Australia into crown colonies admitting Asiatic labour, and looked forward to the government of the Empire by 'an Imperial House of Legislature.' These views, however, he never expressed officially, and his relations with his ministers were invariably amicable. In 1888 he was elected a fellow of the Royal Society. On 18 March 1889 he left New Zealand for England, in 1890 served on a coastal defence committee, and on 28 June 1893 was made a colonel commandant of the royal engineers. A short visit to South Australia in 1892 unfortunately resulted in a severe illness, and thenceforth he lived in retirement, dying on 17 August 1897. (C.B., 1863; K.C.M.G., 1874; G.C.M.G., 1878.)

Jevons, William Stanley (1835-1882), ninth son of Thomas Jevons—a Liverpool iron-merchant who is believed to have constructed the first iron boat that ever floated on sea water—was born in Liverpool on 1 September 1835 and educated at University College school and University College, London (M.A., 1862). In 1853 he was appointed assayer at the Sydney mint, and was engaged in this work from 1854 to early in 1859, devoting his spare time largely to the study of meteorology and climate. His weather reports, published weekly in the *Empire*, were subsequently utilized by the government of New South Wales. Anxious to find a wider sphere of influence, he left Australia in 1859, returned to University College, and studied mathematics and the moral sciences with vigour. His work thenceforth, which had a very wide range (from Shakespeare to Lowe's match tax), had no special connection with Australia; it was mainly concerned with economics, logic, and such allied problems as the probable exhaustion of British coal-supplies, currency investigations, industrial partnerships, the relations between labour and the state, etc. He was, to quote Sir A. W. Ward, 'a statistician of vast industry and rare gifts of combination, and an economist of high original power.' In May 1866 he was appointed professor of logic, political economy, and mental and moral philosophy at Owens College, Manchester; in 1872 he was made F.R.S.; and from 1876 to 1880 he was professor of political economy at University College, London. He was drowned near Hastings on 13 August 1882.

Jewel-fish. See Jewfish.

Jewfish, a name applied to three very different fishes in different parts of Australia. A large marine species, *Sciaena antarctica*, is the jewfish of coastal fishermen in New South Wales; the same fish is called kingfish in the southern States, and in other places butter-fish, dewfish, and mulloway. Its ear-bones (otoliths) are particularly large, and on account of their pearly appearance the species is sometimes called 'jewel-fish;' and the young, because of their brilliance when first captured, are sometimes

Sciaena antarctica

distinguished as 'silver jewfish.' The Australian fish is perhaps not distinct from that known as 'maigre' in European waters. It reaches a length of six feet, and a weight of over 90 pounds, and is an important item in the fish-markets of all Australian capital cities. It sometimes moves in large shoals along the coasts of the southern half of Australia, entering estuaries and inlets, where it is largely captured by net-fishermen. See Teraglin.

The jewfish of Western Australia (*Glaucosoma hebraicum*) is a deep-bodied, perch-like fish, which reaches a length of over 30 inches and is a fine table-fish. It is related to the Pearl Perch (*G. scapulare*) of New South Wales.

One of the catfishes (q.v.) is also commonly known as 'Jewfish.' A.R.McC.

Jews. The first reference to a Jewish element in Australia is that in 1817, when the 20 Jews in *New South Wales* formed themselves into a society for the interment of their dead. Their numbers and resources soon increased, and from 1828 onwards prayers were regularly held at the house of P. J. Cohen in Jamieson-street, Sydney. The first Australian congregation was organized in 1830, for a Jewish population of 345, as the result of a visit by Rabbi Aaron Levy of the London Beth Din (ecclesiastical court), who was despatched to Hobart and Sydney on a special mission by Dr. Solomon Herschell, Chief Rabbi. In 1832 J. B. Montefiore (the first president) and Michael Phillips obtained a grant of land from the government for a burial place, and about the same time a large room in a building in Bridge-street was converted into a synagogue; in the same year the first Jewish marriage in Australasia was celebrated. In 1835 M. E. Rose was engaged in England to become the first Australian Jewish minister. In 1841, the Jewish population having increased to 856 (of whom 500 were resident in Sydney), a site in York-street was purchased for a permanent synagogue, which was opened for divine service on 2 April 1844. One of the founders of the new synagogue, Moses Joseph, became its president. At a later date a second place of worship was opened in a building in Macquarie-street, originally erected as a meeting-house for Quakers. Alexander B. Davis, previously minister at Portsmouth in England and Kingston in Jamaica, became senior minister in Sydney in 1862, and well organized the educational and philanthropic institutions of the young community. The two congregations amalgamated when the present spacious Great Synagogue in Elizabeth-street was consecrated on 4 March 1878. This building, with school premises, cost £27,000. The Jewish population of New South Wales then numbered approximately 3000. In 1903 A. B. Davis retired, and was succeeded by Rabbi Francis L. Cohen, of London, who was installed as chief minister on 25 June 1905, and, being an ordained Rabbi, established a local ecclesiastical court as a branch of the London Beth Din. He has since consecrated three suburban synagogues in Sydney and one at Broken Hill. There is also a small congregation at Newcastle, replacing the older one at Maitland.

The Hebrew Philanthropic Society, which was in 1876 amalgamated with the Orphan Society, and in 1889 with the Sir Moses Montefiore Jewish Home (established in 1887), was first organized in 1833. The institution was in 1923 removed from Dowling-street to Bellevue Hill. The Ladies' Maternity Society, the oldest women's organization in Australia, was founded in 1843, and there are six other Jewish charities in Sydney of long standing. The New South Wales Board of Jewish Education, founded in 1882 and extended in 1906, exercises at a large number of state schools the right of entry and of religious instruction given to all religious bodies by the public instruction act of 1880 (see EDUCATION, PUBLIC). The Maccabean Hall and rooms for the numerous Jewish clubs and young people's movements, forming the New South Wales Jewish war memorial at Darlinghurst, was opened by Lieutenant-general Sir John Monash on Armistice Day, 1923.

In 1842 the first Australian Jewish newspaper was published in Sydney under the title *The Voice of Jacob;* the *Hebrew Standard* (weekly since 1896) and the *Australian Jewish Chronicle* (fortnightly since 1922) are still issued there.

The first attempt to hold regular Jewish services in Victoria then the Port Phillip district of New South Wales, was made in 1839, when small gatherings were held in the home of M. Lazarus. The Jewish Congregational Society was organized in Melbourne in 1841, services being held in the house of Solomon Benjamin. This society developed into the 'Holy Congregation of a Remnant of Israel,' formed in 1844, with A. H. Hart as president. Land for the purpose having been granted by the government, the foundation stone of the first synagogue in Melbourne was laid on 25 August 1847 by the president, Solomon Benjamin. Moses Rintel (q.v.) of Edinburgh, then in Sydney, was appointed minister, and officiated until his death in 1880. In 1853 a new synagogue was built in Bourke-street-west at a cost of £14,000; it was renovated and re-consecrated in August 1877 during the ministry of Dr. Dattner Jacobson. The office of senior minister and president of the ecclesiastical court in Victoria was held from 1884 to 1923 by Rabbi J. Abrahams, Ph.D., who was succeeded by Rabbi I. Brodie. The East Melbourne congregation was founded in 1857, M. Rintel resigning from the Bourke-street synagogue to become minister of the new congregation. The synagogue built in 1859 was replaced in September 1877 by a more suitable building in Albert-street. A suburban synagogue in St. Kilda, which is now the most important Victorian congregation, was consecrated for public worship on 29 September 1872 by A. F. Ornstein and M. Rintel; E. Blaubaum was installed as minister in December 1873, and was succeeded in 1905 by J. Danglow. There are also small congregations at Ballarat and Geelong.

The Philanthropic Society was founded in 1856, and the educational and benevolent activities of the Melbourne community are numerous; prominent among them is the Jewish Aid Society (founded by P. Blashki in 1888) which lends money to struggling traders without any interest, and has an offshoot in Sydney. The *Jewish Herald* (fortnightly) was founded by E. Blaubaum in 1885.

Two years after the colony of *South Australia* was founded, Jacob Montefiore, a pioneer settler, took the lead in congregational affairs; as the number of Jews increased, meetings were held for divine service regularly. In 1848 the present Adelaide Hebrew congregation was founded, Judah Moss Solomon being first president. On 3 September 1850 the synagogue in Rundle-street was consecrated; a grant of land was obtained for a burial ground in 1852; in 1853 the congregation included 38 families and 130 subscribing members. On 26 March 1871 the present synagogue, adjoining the previous one, was consecrated by A. T. Boas, who had assumed his duties in February 1870, and ministered until his death in 1923. The oldest communal institution in Adelaide is the Hebrew Philanthropic Society, which was established on 12 June 1852. The first recorded Jewish marriage celebrated in South Australia took place in 1846.

Although there were Jews in *Queensland* before its separation from New South Wales, their numbers were too small to form a congregation. In the early sixties A. E. Alexander fitted up a room in his premises in Edward-street for regular services. In 1865 Jonas M. Myers arrived in Queensland from Adelaide, and until his death in January 1909 was the mainstay of Queensland Judaism; for many years, when there was no

regular minister, he carried on the duties of the head of the community. In 1867 a cottage in George-street, Brisbane, was fitted up as a synagogue. On 18 July 1886 the present synagogue in Margaret-street was consecrated by A. H. Phillips, assisted by Jonas M. Myers. B. Sinauer was the first president. There is also a small synagogue in South Brisbane, but the congregations in Toowoomba and Rockhampton have ceased to exist.

The Jewish congregation at Perth in *Western Australia* was founded in 1892, and has since rapidly developed. It has a handsome synagogue in Brisbane-street, of which D. I. Freedman has been minister since 1897. The congregation at Coolgardie has ceased to exist.

Sixty-five years ago there was at Hobart in *Tasmania* a considerable Jewish congregation, next to that of Sydney in importance. Its minister, Dr. H. Holzel, was styled 'The presiding Rabbi of the Jews of the Australian colonies.' During the following 30 years the numbers greatly decreased and, except on festivals, the synagogue was closed. Recently, mainly through the instrumentality of S. Benjamin, the congregation was revived. In 1847 a Tasmanian Hebrew Benevolent Institution was formed with H. L. Moses as president. The congregation at Launceston has decayed.

The discovery of gold in the fifties first attracted Jews to Australia in any number; the immigrants were mainly of English nationality, with a few Poles who had lived for some time in England. Subsequent immigration has been of a similar character. A notable feature of the Jewish community in Australasia is the considerable ebb and flow between the States and New Zealand (and to some extent also South Africa), especially of males. The Jewish population of the Commonwealth in 1921 was 21,615, of whom 10,152 were in New South Wales, 7677 in Victoria, 1919 in Western Australia, 1003 in Queensland, 743 in South Australia, and 121 in Tasmania. Members of the pioneer families have taken an eminent part in the development of Australia; among them may be instanced Mr. Justice Isaacs, Mr. Justice Cohen, Judge Cohen, Sir Saul Samuel, Sir Julian Salomons, Sir John Monash, J. B. Montefiore, V. L. Solomon, N. Levi, and G. J. Cohen.

See *The Jewish Year Book, The Jewish Encyclopædia*, and Fowles's *Sydney in 1848*.

Johnson, RICHARD (1757-1827), born at Welton near Hull in Yorkshire in 1757—Bonwick's statement that he was born at Stalham in Norfolk in 1753 is based on a mistaken identification of him with a Richard Johnson who was educated at Magdalen College, Oxford—and educated at the Hull public school and at Magdalene College, Cambridge (Smith scholar, 1780; B.A., 1783), was in 1786 ordained deacon and priest by the archbishop of Canterbury. He had made the acquaintance of William Cowper the poet; and, when the British government decided to make a convict settlement in New South Wales and asked William Wilberforce and John Newton to recommend a suitable chaplain, Cowper suggested Johnson's name to Newton, and on 24 October 1786 he was appointed 'Chaplain to the settlement within Our Territory of New South Wales.' He had already entered on his duties, having visited the hulks at Woolwich two days earlier; and at the beginnnig of December he received from Nepean an order for 'parish necessaries' which included a Bible and prayer-book now preserved in St. Philip's church at Sydney. Johnson sailed in the *Golden Grove*, a store-ship of the First Fleet, which reached Botany Bay on 20 January 1788—a Sunday, so that almost certainly divine service was on that day performed in Australia, though not on land. The transports were brought round to Port Jackson on the 26th—a Saturday—but the beginnings of the landing so occupied the next day that no religious services could be held. Accordingly the first service on land was held on 3 February, Johnson officiating in what is now Macquarie Place under the shade of a large tree. It was a long time before any attempt was made to provide a proper place of worship; for years the services of the Church were performed in the open air, and when the trees were removed services could not be held on wet or boisterous days. The governor and Johnson had for some reason come into collision before they left England; and neither Phillip nor his subordinates made any attempt to provide a place of worship, until Johnson, tired of waiting for the authorities, determined on 10 June 1793 to build a temporary church himself. This was erected close to the present junction of Castlereagh- and Hunter-streets (where a memorial of it was erected in 1925), at a cost of £67 12s. 11½d., which after long delay was refunded to Johnson. He had it finished in time to hold his first service in it on 25 August. Up to Hunter's arrival in 1795 the chaplain was treated with neglect and indifference both by Phillip and by Grose; the latter in particular described him as 'one of the people called Methodists, a very troublesome, discontented character . . . . from whom I have received treatment very unbecoming his character as a clergyman to offer.' Johnson consoled himself with agriculture. He had a grant at Camperdown, and is said to have cultivated with much success a farm and orchard at Ryde, growing fine orange-trees from seeds he had brought from Rio de Janeiro; but the evidence for this Ryde farm is weak. After Hunter's arrival Johnson received more consideration. Hunter describes him as 'a most dutiful son of the Church of England . . . . a Moravian Methodist . . . . I believe him to be a very good, pious, inoffensive man.' In 1794 Samuel Marsden (q.v.) arrived as assistant chaplain and relieved Johnson of a large portion of his duties, which by that time extended to the settlements beyond Parramatta. On 1 October 1798 the temporary church was consumed by fire, in circumstances which pointed to arson, and the convicts were blamed for thus avoiding the enforcement of Hunter's orders that they were all to attend divine service. The governor offered a reward for the conviction of the culprits and, so that they should not gain anything by their crime, had a store-room near the Cove prepared for service by the following Sunday. Johnson seems to have been a sensitive and retiring man, who felt deeply the position in which he was placed, and conscientiously performed his duty under trying circumstances; hard work and lack of sympathy wore him out, and on 12 July 1798 he applied for leave of absence. On 28 September 1800 he left the colony with Hunter in H.M.S. *Buffalo*, arrived in England in the following May and took a two years' rest; asked to resume his duties in New South Wales, he refused, resigned his post, and for some time took the curacy of West Thurcock near Grays in Essex. In 1810 he was appointed to the rectory of St. Antholin in London and in 1817 was inducted into the perpetual curacy of Ingham in Norfolk. Both these livings he held till his death on 13 March 1827. See CHURCH OF ENGLAND.

Johnston, GEORGE (1764-1823), born at Annandale in Dumfriesshire, Scotland, on 19 March 1764, joined the marines on 6 March 1776, when but 13 years of age (2nd lieutenant, 1776; 1st lieutenant, 1778; captain-lieutenant, 1789; major, 1800; lieutenant-colonel, 1808), and saw service in North America (New York and Halifax) and the East Indies, where he was in engagements with the French fleet and on 6 July 1781 was severely wounded. On his return to England in 1785 he obtained leave of absence, and on resuming duty volunteered to accompany the expedition then being sent to New South Wales under Arthur Phillip, as first lieutenant of Ross's company of marines, which sailed in the First Fleet on board the *Lady Penrhyn*. On arrival in Port Jackson he was made aide-de-camp to Phillip, and retained the position under Hunter. By October 1788 he had seen enough of the new land to decide on a longer stay than was allowed to the majority of his fellow officers; and on 10 April 1792 Phillip gave him command of a company of the New South Wales Corps which had been raised from the marines who preferred to stay in the colony. On 12 February 1793 he was granted 100 acres on the main road from Sydney to Parramatta, a block which he named 'Annandale,' and which (with additional land that he acquired in later years) is now the Sydney suburb of that name. There, in 1797, he planted the first Norfolk Island pines brought to Australia.

Hunter in 1796 sent him to relieve King as lieutenant-governor of Norfolk Island, but ill-health soon after his arrival there forced him back to Sydney even before King could leave the island. In 1800, put under arrest by his superior officer William Paterson (q.v.) for giving a sergeant of the corps part of his pay in spirits at an exorbitant price, he accused Paterson of persecution, refused to be tried by court martial in the colony, appealed to the military authorities in England, and was sent to England in the *Buffalo*, in which Hunter returned also. The case is important for three reasons: the authorities refused to try colonial cases in England, and remanded Johnston to Sydney for trial; they then discovered that a properly constituted general court martial could not be had in Sydney, owing to the lack of officers, and so decided to abandon all proceedings; finally, King avowed himself of opinion that there was not an officer in the corps or the colony—except Paterson himself—who had not trafficked in spirits and made a good deal of money by so doing. Johnston returned to Sydney on 16 October 1802.

Early in March 1804 a dangerous mutiny broke out among the convicts employed in the Castle Hill district, and Johnston's gallantry in pursuing and detaining a large body of rebels with a very small force of soldiers and volunteers (30 against 266, according to King), arresting the ringleaders, and dispersing the rest, was highly commended by King in a general order. With Governor Bligh Johnston was from the first on bad terms. He was above all things a soldier, jealous for military discipline and the honour of his corps; several of his misunderstandings with King had been due to this. Bligh was irritable, hasty, foul-mouthed and meddlesome, and in October 1807 Johnston was forced to complain of his abuse and interference with the troops to the commander-in-chief in England. When, therefore, in January 1808 John Macarthur (q.v.) and his military friends called on Johnston to arrest Bligh and assume command of the colony as lieutenant-governor, no motive of friendliness or personal respect for the governor debarred him from drastic action. He was neither the prime mover (Macarthur was that) nor even an actively interested participant; he was a commanding officer whose subordinates had been insulted and accused of treason, and who found himself in a position to right their wrongs and punish their persecutor. Bligh once safely under arrest, Johnston sat back and allowed Macarthur to govern. Superseded in June 1808 by Foveaux (who approved of his conduct towards Bligh but not of his subsequent administration), he persuaded Foveaux's successor Paterson to let him go to England in the *Admiral Gambier* for a full investigation. He sailed on 28 March 1809, was tried in May-June 1811, and returned to the colony as a private citizen on 30 March 1813. What the British authorities thought of his actions is proved by their treatment of him; they tried to drop the whole business, only court-martialled him on his own insistence, punished him merely by cashiering—the mildest possible penalty for such a mutiny—and let him go back to New South Wales. Their treatment of Macarthur, the real head-mutineer, was very different.

The rest of Johnston's life was uneventful. He resided at Annandale, managing his various properties and enjoying Macquarie's friendship, until his death on 3 January 1823. Macquarie, indeed, held so high an opinion of him as to obtain from the British military authorities a decision to restore him to his full rank in the army; unfortunately this decision was not carried out before his death.—His son ROBERT JOHNSTON (1792-1882), born at Sydney on 9 March 1792, was in 1800 entered by Governor Hunter on the books of H.M.S. *Buffalo*, being thus the first Australian-born rating in the navy. He was educated at Newington Butts, near London, under Hunter's guardianship, and served in the squadron that embarked Sir John Moore's army after Coruna, as well as in many minor naval actions of the Peninsular war and in the American war of 1812. In 1823, when he inherited Annandale from his father, he retired from the navy and devoted himself to Australian affairs, but refused to enter politics. He discovered and explored the Clyde River in southern New South Wales, and determined the sources of the Warragamba. He died at Annandale on 8 September 1882—Robert's brother George was appointed to the commissariat department by Macquarie in 1814, and given charge of the military magazines at headquarters; in 1819 he was made superintendent of government stock, but early in 1820 was killed by a fall from his horse. Macquarie greatly lamented his loss, describing him as 'this highly Useful, Meritorious and excellent, worthy Young Man . . . . a Most Useful and Valuable Officer.'

Jollytails, small freshwater fishes (*Galaxias*) rarely attaining a length of eight inches. Their occurrence in the streams of all lands that encircle the Antarctic renders them of special interest to zoologists, and their distribution has been quoted as evidence in support of an argument for the existence of former land-bridges. However, the fact that some species descend to salt water to spawn, and that their young pass the first portion of their lives at sea, largely discountenances the value of such evidence. A number of species are known from streams of the southern half of Australia and Tasmania, but they are so variable in form and colour that the limits of any one are difficult to determine.

They fight their way upstream against the swift currents formed by melting snow, wriggling and swirling in the eddies with a vivacity that has earned them their vernacular name. One species, *G. attenuatus*, is common in the coastal streams of southern and south-eastern Australia, Tasmania, New Zealand, the Falkland Islands, and South America. It migrates to salt water to spawn; in New Zealand the young are captured together with those of an allied fish (*Retropinna*) and marketed as 'whitebait.' A species has been recently discovered in New Caledonia, and others occur in South Africa. In Australia jollytails usually pass under various borrowed vernacular names, such as gudgeon, minnow, mountain trout, lake trout, native trout.

A.R.McC.

Jorgensen, JORGEN (1780-1841), according to his own account, was born at Copenhagen in 1780, locally educated, and at the age of 14 apprenticed to the master of an English collier trading between Newcastle and Copenhagen. When 18 years old he left the collier, and shipped aboard a South Sea whaler that was going to the Cape of Good Hope; at the Cape he transferred into a schooner employed on government service, and in Algoa Bay witnessed an exciting fight between H.M.Ss. *Rattlesnake* and *Camel* and the French frigate *La Préneuse*. Returning to the Cape, he joined the *Lady Nelson*, then on her way under Lieutenant Grant to survey the Australian coasts.

So far his own account has been followed; but here discrepancies are apparent. In the first place, Grant did take a Dane aboard at the Cape, but he was 'a Dane sentenced to transportation.' In the second place, Jorgensen states that the first point the *Lady Nelson* made in Australian waters was King Island—'we sailed round it, and it was named after Capt. King, R.N.' Now the first point the *Lady Nelson* made was Cape Northumberland, and she did not see King Island at all on that voyage. But the *Harbinger*, which was close on her heels, did see King Island (although her first landfall was Cape Otway); also, the *Harbinger* was the schooner in which Jorgensen visited Algoa Bay; and, further, on 24 January 1802 Murray in the log of the *Lady Nelson* mentioned that 'John Johnson'—under which name Jorgensen was at that time borne on the ship's books—identified a rock off King Island, 'having seen it when with Mr. Black, commander of the *Harbinger*.' It seems probable, therefore, that Jorgensen's memory was unreliable, and that he reached Sydney in the *Harbinger*, transferring later to the *Lady Nelson*. That he did serve aboard that vessel is proved by a letter of Macquarie's (30/5/1814), in which he states that Jorgensen served in her under the name of Johnson or Jansen; but the ship's own papers (many of which are lost) have only three possible references to him—Murray's entry above-mentioned, an earlier entry of Murray's (23/11/1801) referring to 'John Johnston, cabin servant,' and an entry in the books of H.M.S. *Buffalo* (to which the *Lady Nelson* was at one time a tender) concerning 'John Johnstone' of Copenhagen, aged 37 in October 1802, who was '2 Mate or Mid' of the tender from 13 December 1802 to 26 April 1804. It is obvious that, if Jorgensen was 37 in 1802, he was born considerably earlier than 1780. His statements, therefore, cannot be too trustfully relied on. He claims, for instance, that in 1801 he accompanied Captain Baudin of the *Géographe* on a journey up the Hawkesbury, and gives details of the visitor's conduct; but we know that Baudin deliberately refused to leave Sydney, and tried to prevent his officers from doing so—it must therefore have been Bailly or Péron, whom King did send on a trip up the Hawkesbury, that Jorgensen mistook for Baudin.

In 1804 he went sealing to New Zealand, and then whaling off the Tasmanian coast; he claims to have struck the first whale killed in the Derwent. In the *Alexander* whaler he visited Norfolk Island, New Zealand (where two Maoris were kidnapped in the Bay of Islands), Tahiti (where also two natives were taken aboard), St. Catharine's Island in southern Brazil, and St. Helena, thence reaching London in June 1806. Jorgensen there handed over the Maoris and Tahitians to Sir Joseph Banks, who did his best for them; but within a year three were dead, and the fourth managed to earn his living as a carpenter.

Jorgensen returned to Copenhagen just in time to see it bombarded by the British fleet under Admiral Gambier. This operation threw Denmark into Napoleon's arms, and Jorgensen commanded a small privateer in the naval war that followed, being captured on 2 March 1808 by the sloop *Sappho* off Flamborough Head. He at once visited Banks as a prisoner of war and was sent off by him on 29 December to Iceland with a cargo of provisions for the inhabitants, who had been reduced to starvation-point by the British blockade. His first trip prospered. On his second, in the *Margaret and Anne*, it was found that the Danish governor, Count Trampe, had forbidden trade with the English; so the owner of the vessel (who had letters of marque from the British government) solemnly deposed the governor and established Jorgensen in his place. Jorgensen administered the island as 'protector' from 20 June to 11 July, establishing trial by jury and a 'free representative government,' halving the taxes, augmenting official salaries, constructing harbour defences, raising a troop of eight cavalry, and hoisting 'the ancient and independent flag of Iceland.' Unfortunately for him, on 11 July H.M.S. *Talbot* anchored in Reykjavik harbour, reinstated Count Trampe, and took Jorgensen back to England to be tried for breaking his parole—which, as he plaintively remarks, he had never given. The commander of the *Talbot*, it appears, was shocked at the idea that a man who had been apprentice in a British collier and midshipman aboard a British surveyship should presume to administer a kingdom.

Jorgensen was imprisoned for a year and paroled at the end of that time, and then led an idle existence in Reading and London, during which he learnt to gamble. In 1812-13 he went again a-voyaging, but ended up in London, found Banks hostile, and fell in with a certain Count Dillon, a French ex-prisoner who was on espionage work, and who imparted to him (as a former prisoner and presumably an enemy of Britain) details of a Franco-American plot to attack the Australian settlements with four French frigates and one from the United States (Jorgensen's memory, playing him false as usual, made him state in after years that two were to be French and two American). He at once reported the plan to the colonial office, but Bathurst refused to believe him, though someone in the office drew up a scheme for intercepting the raiders. As it happened, an American ship, the *Essex*, was already in the Pacific, and captured a number of British vessels; but no French ships joined her, and no attack was

made on New South Wales. Still, the raid of the *Essex* gave some credibility to Jorgensen's report, and for the next few years he was employed by the foreign office as a secret service agent on the continent of Europe; during this period, he says, he was at Waterloo during the battle, and a year or so later met Goethe and Blucher. But the passion for gambling had completely overpowered him, and he sank lower and lower, being condemned in 1820 to seven years' transportation for pawning his landlady's goods. Friends interceded for him, and he was kept at Newgate as hospital assistant, and after a while pardoned; but gambling brought him back to prison with a life sentence, and after three more years in the Newgate hospital he was transported to Tasmania, reaching Hobart on 29 April 1826. There Arthur, who considered him 'a violent political character,' detained him under his own eye as a convict clerk, but afterwards allowed him to enter the service of the Van Diemen's Land Company, and in exploring the country between the Shannon River and Circular Head he had exciting adventures with aborigines, bushrangers and floods. Later he became district constable at Oatlands, and showed resource in dealing with bushrangers and blacks, being for two years in charge of parties organized to protect the settlers. He was one of the few who took an intelligent interest in the aborigines, and collected a vocabulary of their language. His work, which was rewarded with a pardon, helped to pave the way for G. A. Robinson (q.v.). He was given 100 acres of land, but sold it. Cured of the passion for gambling which had been his ruin, he married a woman who bullied him, wasted his money in speculations, and died in poverty and obscurity.

In a copy of the *Hobart Town Almanac* for 1835 with the autograph of Dr. J. D. Hooker (son of Sir William Hooker) Jorgensen's name has been written at the beginning and end of an article entitled 'A Shred of Autobiography,' and the following memorandum is attached:—'J. J. accompanied my father to Iceland in 1809. I saw him in Van Diemen's Land in 1840, a disreputable-looking man . . . . On my return to V. D. L. in 1841 I found that J. J. was dead, his body having been found in a ditch.'

Jorgensen was a prolific writer. Hatchard of Piccadilly published his *State of Christianity in the Island of Otaheite* (1811), and Cadell and Davis his *Travels Through France and Germany* (1817), and he wrote a number of semi-religious tracts on the evil effects of gambling. In Tasmania he published not only the 'Shred of Autobiography' already mentioned—which is the main authority for his life—but a sequel to it in the *Almanac* of 1838, and *Observations on the Funded System* in 1831. His *Rise, Progress and History of the Van Diemen's Land Company*, printed in the Hobart *Colonial Advocate* in 1828, was published as a pamphlet in London in 1829. A great deal of unpublished matter by him is in the British Museum and in the Mitchell Library at Sydney.

See J. F. Hogan's *Convict King* (London, 1891).

W.J.

Judiciary, The. In the Judiciary of Australia three main elements are observable: (1) a complete common-law system of courts in each State, including (at all events in the case of the supreme courts) jurisdiction in equity, bankruptcy, probate, divorce, and admiralty; (2) the high court of Australia, with both original and appellate jurisdictions; (3) many special courts of limited jurisdiction. Matters relating to the personnel, position, tenure of office, and remuneration of judges and magistrates are for the purposes of this article grouped together in a fourth section.

1. The earliest settlers naturally brought the English common law with them, as the test by which crime should be known and civil disputes ended; but the dispensing of law was for a time in the hands of an administration penal and military in character (see CONSTITUTIONS). It took time to build up in this new land complete systems of courts which should dispense the common law, whereby our liberties are better safeguarded than are those of foreigners by the most solemn guarantees of their written constitutions. A brief account only of the process of establishment and the scope of these courts is here attempted.

Charter of Justice.—In 1823 the statute 4 George IV c. 96 authorized the King, by charters or letters patent under the seal of the United Kingdom of Great Britain and Ireland, to erect and establish courts of judicature in New South Wales and Van Diemen's Land respectively, to be styled 'the Supreme Court of New South Wales' and 'the Supreme Court of Van Diemen's Land.' His Majesty by letters patent (known in New South Wales as the Charter of Justice of 13 October 1823) proceeded to 'grant direct ordain and appoint' that there should be 'within that part of our Colony of New South Wales situate in the Island of New Holland a Court which shall be called the Supreme Court of New South Wales to be a Court of Record.' Section 2 of the statute had provided that the said courts 'shall have cognisance of all pleas, civil, criminal or mixed,' and thereby settled their jurisdictions as equivalent in their respective colonies to that in England of the superior courts of the realm held at Westminster. Section 9 had given these supreme courts an equitable jurisdiction of the same character and extent as that of the lord high chancellor of Great Britain in England. In addition, by the combined effect of the act and the charter, an ecclesiastical jurisdiction was conferred upon the court, to deal with wills, probate and the administration of the estates of deceased persons 'as the same is and may now be used in the Diocese of London.' There was also a rudimentary jurisdiction in insolvency. Jurisdiction in matrimonial causes, bankruptcy, and admiralty has since been added; that in admiralty cases was not given until 1911, but before that it was usually (by arrangement) a judge of the supreme court who presided in vice-admiralty. The authority was for New South Wales and Van Diemen's Land more explicitly defined by the temporary act 9 George IV c. 83 s. 3, and made permanent by 5 and 6. Vic. c. 76 s. 53. See also 6 Will. IV. No. 12, setting at rest doubts as to the powers of the court.

In each Australian colony in turn supreme courts were erected, and invested with like authority. This authority includes control by the court of its own officers, and of the legal profession, and of inferior courts by means of appeals and such writs as those of prohibition, mandamus, certiorari and quo warranto. The processes of establishing a supreme court differed in each colony. For Victoria see 13 and 14 Vic. c. 59, which recited it to be 'expedient that the district of Port Phillip, now part of the Colony of New South Wales, should be erected into a separate colony' (sec. 1.). The colony was formed, and a governor and legislative council

provided; the local act 15 Vic. No. 10 made provision for the better administration of justice in the colony of Victoria, and the supreme court was founded thereunder. This provision, however, was insufficient, and the act 18 and 19 Vic. c. 55 (which really gives Victoria its constitution) provided completely in schedule 1 for its supreme court. For Western Australia see 10 Geo. IV c. 22; for South Australia 5 and 6 Vic. c. 61; Queensland was not separated from New South Wales until 1859, by which time a supreme court under a resident judge had been established for the Moreton Bay district. See the Queensland statutes 23 Vic. No. 13 and 31 Vic. No. 23. All the statutes from 9 Geo. IV c. 83 that deal with the constitution of New South Wales (inclusive of Queensland), up to the order in council of 1859 for the erection of Queensland into a separate colony, are collected in vol. i of Pring's *Statutes in Force in Queensland, 1862*. They were consolidated in the Queensland constitution act of 1867.

The statute 4 Geo. IV c. 96, which laid the foundation for the charters of justice of New South Wales and Tasmania, provided also for courts of general or quarter sessions, and authorized the governor of New South Wales to institute courts of request to determine all civil suits under £10 (sec. 20). It provided further for the constitution of a council (the first nominee legislative council) in New South Wales, and the governor with the advice of the council was given power 'to make law for the peace, welfare and good government of the Colony.' Under this authority various local acts were passed for the institution and regulation of courts of general and quarter sessions in New South Wales, and for the establishment of jury panels. By 1834 such courts had been established at Sydney, Parramatta, Windsor, Campbelltown, Maitland, and Bathurst. By separate but similar steps courts of request for the recovery of small debts were established, at first in Sydney and the nearer townships, till in 1839 a local act (3 Vic. No. 6) recited that 'the increase of population in the towns of Melbourne and Port Macquarie respectively makes it expedient and necessary for the interest of the said towns and their neighbourhoods that Courts of Request should be holden in each,' and proceeded to establish them.

Further steps in the completion of our judiciaries are marked by the passing of justices' acts and of district courts or county courts acts. The Victorian county court act and New South Wales district courts act follow fairly closely the provision of the English county courts act. These courts are intermediate between the minor courts and the supreme courts in their respective States; the judges of the district (county) courts are also chairmen of quarter sessions for their respective districts, and thus have both civil and criminal jurisdictions. They also, as in England, act as courts of appeal from justices. Claims as large as £400 may be brought in New South Wales in the district court, but not cases where title of land is *bona fide* in dispute, nor equitable claims. In Victoria a county court may deal with all personal actions where the amount or damages sought to be recovered is not more than £500, and may also exercise a very complete equity jurisdiction in many kinds of suits and matters within the monetary limit.

The justices acts in each State are framed upon the model of those first passed in England at the instance of Sir John Jervis, and give to police or stipendiary magistrates, and to justices of the peace, criminal and quasi-criminal jurisdiction. Their courts deal in a summary way with such criminal matters as may by law be so dealt with, and, where this is not so, can commit prisoners for trial by jury in a higher court. They also deal completely (subject to appeal to quarter sessions) with police offences and many quasi-criminal matters. This jurisdiction of the minor courts on the criminal side is coupled on the civil side with the jurisdiction derived from the early courts of request, now extended in some cases to claims up to £50 in value.

Not all the States are equipped, as are New South Wales and Victoria, with three grades of court. In less populous States there are two grades of court only, the position of the minor courts being somewhat enlarged, though not equal to that of a county or a district court or of a court of quarter sessions. All matters outside their jurisdiction fall naturally in such States into the sphere of the supreme court. In Western Australia a trace of the former crown colony type of government is seen in the style of the 'resident magistrates' who preside in its lower courts.

By these various steps there had been instituted before federation in each colony of Australia a complete judicial system, dispensing the common law of England with amendments made by the general statutory law up to date of devolution, and comprising the equitable and other jurisdictions already mentioned. At the head of the system in each colony with plenary powers (subject, however, to appeal to the privy council) was and is the supreme court of each State.

2. *The High Court.*—Soon after the establishment of the Commonwealth a high court of Australia, contemplated by the judicature provisions in the constitution (sections 71-80), was established. This court has both original and appellate jurisdiction. Its original jurisdiction is derived from the constitution, and by section 75 thereof includes matters arising out of treaties, affecting consuls, for or against the Commonwealth, between States or residents of different States, and cases where writs of prohibition, mandamus or injunction are sought against a Commonwealth officer. Further original jurisdiction has been given to it by the judiciary acts (sections 24 and 30) and by special acts, such as the customs act of 1901 (section 245), the property for public purposes acquisition act of 1901 (section 15) and the Commonwealth electoral act of 1918, part 18.

The appellate jurisdiction of the high court extends to all judgments, orders, etc., (1) of justices of the high court of Australia exercising federal jurisdiction; (2) of any other federal court or court exercising federal jurisdiction; (3) of the supreme courts of States in the exercise of the jurisdictions of their States; (4) of the inter-State commission, as to questions of law only. The high court is thus both a federal court of appeal and a national one. In its appellate capacity it has for the first 20 years of the Commonwealth done its best-known work. Federation did not abolish the right of appeal from the supreme court of a State to the privy council, but gave an option of appeal to the high court, of which the public and profession at once availed themselves. This fact, coupled with the ability of the judges who first constituted the high court (Sir. S. Griffith, Sir E. Barton, and R. E. O'Connor), gave it an immediate ascendency, notwithstanding the power and dignity of the various supreme courts. But al-

though appeal to the high court is most common, a number of appeals are still made to the privy council under the right reserved by the constitution. For litigants in any court of original federal jurisdiction the appeal is to the high court. A litigant in the appellate jurisdiction of the high court can appeal to the privy council only by special leave, obtainable for special cause from the privy council itself; but, if the case involves a question of constitutional power, not even the privy council can grant leave to appeal, unless the high court certifies the case to be one which ought to be determined by His Majesty in Council. To grant such a certificate has not been usual.

The Commonwealth government has not so far found it necessary to establish inferior courts for the exercise of original jurisdiction, utilizing instead the very complete State judiciaries. Thus persons charged with offences against the laws of the Commonwealth are in general (by the judiciary act of 1903, s. 68) triable by State courts, while civil matters (such as appeals from assessment for federal taxes, or assessments of compensation) are deputed to the civil courts of the State in which they arise.

3. In the development of each colony, and of Australia generally, it has been necessary to create special courts which are of themselves no part of the systems already discussed. For example, each colony found it necessary to set up courts to deal with questions relating to crown lands, for the purpose of settling or determining settlers' rights, especially a settler's rights as against the crown. Such courts deal with nothing but crown land matters, and are not necessarily presided over by lawyers. There are, besides, many other courts whose duties are confined purely to the purposes of the creating statute; such are courts of marine enquiry, of review (in taxation matters) and mining courts (held by a mining warden). In many cases these are presided over by a judge or police magistrate. The most important of these special courts are undoubtedly the industrial courts established within recent years by each State, as well as by the Commonwealth, to deal with disputes extending beyond a State (see INDUSTRIAL LAW).

4. Since the creation of the supreme court of New South Wales with Francis Forbes (q.v.) as chief justice, many eminent judges have filled the supreme court benches of the various States. Among them Sir Alfred Stephen, Sir James Martin, and Sir F. M. Darley were chief justices of New South Wales; Sir W. F. Stawell, George Higinbotham, and Sir John Madden filled the same position in Victoria, as did Sir Samuel Way in South Australia and Sir S. Griffith in Queensland.

By the charter of justice the first chief justice of New South Wales was given rank and precedence 'before all other subjects whomsoever within the colony of New South Wales aforesaid,' and the like position has been enjoyed by subsequent chief justices both in this and other States. When the State governor is absent, or the position temporarily vacant, it is usually filled in each State by the chief justice as lieutenant-governor. Salaries range from £3500 (in the case of the chief justice of the high court and of the more important States) down to £600 per annum or thereabouts in the case of magistrates. The positions of judges of the supreme court and of county or district courts are regulated by appropriate acts of parliament. Their tenure of office used to be 'during good conduct'—that is, practically for life or till voluntary retirement. In most cases it is so still, but in New South Wales and Queensland (as in New Zealand) recent statutes have fixed age-limits (70 and 72 years) at which a judge must retire. The stipendiary and police magistrates and other salaried justices are dealt with in the civil service acts of their respective States.

K

Kangaroo Paws, the popular name of several species of *Anigozanthos*, a genus of the family Haemodoraceae endemic in Western Australia. The fused calyx and corolla form an elongated tube, recurved at the upper end, with the segments produced into teeth. The flowers thus formed are covered with a woolly coat of plumed hairs, the whole bearing a striking resemblance to the paw of the kangaroo. In *A. rufa* the resemblance is accentuated by the reddish-brown colour of the hairy coat. Other species have green, yellow, or red flowers, or a blend of two or more of these colours.

Kangaroos and Wallabies, a genus (*Macropus*) of diprotodont marsupials abundant in most of the unsettled or sparsely settled areas of Australia (including Tasmania), and represented also in Papua and the Aru Islands. The distinction between kangaroos and wallabies is mainly a mere matter of size; at one time it was proposed to confine the generic name *Macropus* to the larger forms (kangaroos), referring the smaller (wallabies) to a distinct genus, *Halmaturus*. But, apart from size, the differences between the two forms are so slight that the second genus is no longer recognized, and both series are referred to *Macropus*. This, however, does not comprise the rock-wallabies, the nail-tailed wallabies, the hare-wallabies, the Dorcas kangaroos, the tree-kangaroos or the musk-rat kangaroos—all of which are dealt with in separate articles.

All the marsupials above mentioned, together with *Macropus* itself, compose the family Macropodidae. The members of this family are all (except the tree-kangaroos) adapted to living on the ground, predominantly bipedal, and able to progress rapidly by a series of leaping movements in which the fore-limbs, in most cases, take no part. The fore-limbs are smaller than the hind-limbs, and are in all cases provided with five well-developed digits, almost equal in size, and ending in curved and pointed claws. The longer and more powerful hind limbs have usually only four toes; the first toe is undeveloped, the second and third toes are small and (as is universally the case in the diprotodonts) united by a web of skin (syndactylous), the fourth is much the largest and forms the main support for the weight of the body. The fifth toe is comparatively small and weak, like the second and third. The tail is long and powerful, and aids in supporting the body. All the teeth are provided with roots. There are three pairs of incisors in the upper jaw, and one pair in the lower; a small canine may be present in the upper jaw; in both upper and lower jaws there are six grinding or cheek-teeth on each side, of which the last four (the true molars) have the crowns provided either with tubercles or with transverse ridges. Females have a large pouch (*marsupium*), with the opening directed forwards. The food is of a vegetable nature, herbage or leaves for the most part.

The species of *Macropus* are characterized by the comparative length of the hind- as compared with the fore-limbs, the long, pointed ears, and the thick, tapering, evenly-furred tail. The innermost incisor tooth of the upper jaw is only slightly longer than the others; the two lower incisors are nearly horizontal in direction, and are capable—owing to the mobility of the right and left halves of the jaw—of working against one another to a limited extent, like the blades of a pair of shears. The canine is usually very small or absent altogether; the crowns of molar teeth bear transverse ridges (usually two on each connected in the middle by a 'bridge'), and increase in size backwards. In the pouch of the female are four teats.

Of the larger species (kangaroos) there are at least four, all Australian; none occur in Papua.

One is the Great Grey Kangaroo (*Macropus giganteus*), described by Shaw—as *M. major*—in the *Naturalists' Miscellany* for 1790. This is the boomer, or old man kangaroo, found in all parts of the Australian mainland except the centre and the extreme north. It is one of the largest of the kangaroos; owing to its abundance and wide distribution, and to its being commonly represented in European and American zoological gardens, it is probably the best-known member of the tribe, and bulks more largely in scientific and popular literature than any other Australian marsupial. A full-grown male specimen measures about five feet from nose to base of tail; the tail is about three feet long. The fur is short, close and rather woolly, of a grey-brown colour above and almost white underneath.

The great grey kangaroo usually inhabits open eucalypt forest country, such as is typical of the more inland parts of Australia; during the extreme heat of summer, however, it often takes shelter in thicker belts of timber and scrub. It goes about in small parties, which are only casual and unorganized associations without leadership or coherency. Its numbers have become greatly reduced of late years, owing to the advance of settlement, which has subjected it and its allies to wholesale destruction in great 'drives,' in which sometimes many thousands have been slaughtered. This form is represented in Tasmania and Kangaroo Island by a darker variety (*M. fuliginosus*), now almost extinct.

Another widely distributed species is the Great Red Kangaroo (*M. rufus*) which may somewhat exceed the great grey kangaroo in dimensions, and differs from it in the prevailing reddish colour of the fur and the presence of certain black-and-whitish markings on the face;

the females are of a much lighter, bluish-grey colour. The Wallaroo (*M. robustus*) is not so tall as the great grey or the red kangaroos, but is stouter and heavier in the body. Its general colour is a dark smoky-brown, deepening to

Red Kangaroo (*Macropus rufus*).

black at the ends of the limbs and tail; so variable are its colours and character that ten forms have been described, including the variety *isabellinus* from Barrow Island, Western Australia. It inhabits mountainous districts throughout Australia, except in the south-western corner. The remaining large species of *Macropus*, the Antelope Kangaroo (*M. antilopinus*), is confined to the Northern Territory.

Of the larger wallabies belonging to the genus *Macropus*, the most widely spread species is the common Scrub or Black-tailed Wallaby (*M. ualabatus*), which is numerous in various districts in New South Wales and Victoria, and is represented in Queensland by a nearly allied form (*M. ualabatus* var. *apicalis*). The scrub wallaby measures about 33 inches from snout to base of tail, the tail being about 26 inches in length. It has a rather thickset body, with long, thick and rather coarse fur, of a prevailing dark reddish-grey colour, paler below, with black tail and black extremities to the limbs. The Queensland variety usually has the tail tipped with white. Considerably larger than the scrub wallaby is the Red-necked Wallaby (*M. ruficollis*) which occurs in New South Wales and Victoria, and is represented in Tasmania by Bennett's Wallaby (*M. ruficollis* var. *bennetti*), smaller and darker in colour than its near relative of the mainland. The slighter build, the longer ears, and the bright red of the fur at the back of the neck also distinguish it from *M. ualabatus*. Other representatives of the larger wallabies are the Agile Wallaby (*M. agilis*) of Queensland, the Northern Territory, and New Guinea, the Black-striped Wallaby (*M. dorsalis*), which inhabits the inland districts of New South Wales and Queensland, Parry's Wallaby (*M. parryi*), which occurs in the mountains of northern New South Wales and Queensland, and the Black-gloved Wallaby (*M. irma*), a native of Western Australia.

Of the smaller wallabies belonging to the genus *Macropus*, one of the most widely known is the Pademelon (*M. thetidis*), which occurs in Victoria, New South Wales and southern Queensland. The pademelon is a graceful little animal of a total length (including the tail) of about forty inches; it has thick and soft fur, grey on most of the upper surface, reddish on the neck, and nearly white underneath, with brown hands, feet and tail-extremity. It differs from other wallabies in keeping the forepaws wide apart when it leaps, instead of bringing them together. Other small forms are the White-throated Wallaby (*M. parma*), confined to New South Wales; the Red-legged Wallaby (*M. wilcoxi*) of New South Wales and southern Queensland, and the allied *M. stigmaticus* of north-eastern Queensland; the Short-tailed Wallaby (*M. brachyurus*) of south-western Australia; the Dama Wallaby (*M. eugenii*) of south-western and southern Australia and the adjacent islands; the Rufous-bellied Wallaby (*M. billardieri*) of Tasmania and some islands of Bass Strait; and the Toolach Wallaby (*M. greyi*) of southern and south-eastern Australia. See RAT-KANGAROOS. For references see MARSUPIALS.

Kavel, AUGUST, about whose early life nothing is known, was in 1826 appointed minister of the evangelical Lutheran church at Klemzig in eastern Brandenburg, but resigned in 1835 because the Prussian government imposed on the Lutherans a new and (as they contended) heretical liturgy. His congregation, along with many others, being determined not to yield to the government in matters of religion, sent Kavel to London early in 1836 to interview George Fife Angas (q.v.) about arranging for their settlement in the new colony of South Australia. Angas was interested, and did all in his power to promote the migration; but the Prussian government put all sorts of obstacles in the way, and it was not until July 1838 that the first shipload of Prussian and Silesian exiles left Hamburg in the *Prince George*, picking up Kavel at Plymouth and reaching South Australia on 16 November. Other batches followed in the *Bengalee*, *Catherine*, and *Zebra*. During the interval Kavel had worked hard among the Germans in London, and helped Angas greatly in establishing a German mission to the South Australian aborigines. The first settlement in South Australia, made about three miles from North Adelaide, was named Klemzig; there, and afterwards (when German villages grew up along the range) from Angaston to Nairne, Kavel devoted himself to maintaining among his flock a high standard of probity and industry. He died on 11 December 1859.

For a fuller account of the migration see Hodder's *George Fife Angas*, ch. vii.

Kelly, EDWARD (1854-1880), born in 1854 near Wallan in Victoria, was the eldest son of a certain John Kelly who had been transported to Tasmania in 1841 for attempts to shoot his landlord. (Another account gives his crime as killing a man in a faction fight, and the date of his transportation as 1834.) Having served his sentence John Kelly went to Victoria and settled at Wallan, 40 miles from Melbourne, where an easy road through the main range facilitated his stealing horses on the Melbourne side and getting them away through the hills for sale in the Murray valley; but his operations interfered with those of a stronger horse-stealing gang, which one night captured him, his family, and a family of Quinns that worked with him, took them to the top of the range, and bade them go north on pain of death if any of them

were ever discovered on the Melbourne side again. The Kellys and Quinns therefore made their way to the King valley and settled in the hills above Greta, near Glenrowan, resuming their trade of cattle- and horse-stealing with much success. John Kelly died in 1865, leaving a family of seven—Ned, Jim (born in 1856), Dan (born in 1861) and four daughters, of whom Kate is the best-known. All the boys were in trouble from their early youth. Ned in 1870 was arrested as an accomplice of the bushranger Harry Power, but betrayed him and so escaped punishment. Jim in 1871 incurred a five years' sentence for horse-stealing, served it, went to New South Wales, 'stuck up' a number of people there, and got off with a ten years' sentence which kept him safely out of the way while his brothers were becoming notorious. Ned in 1871 was given a three years' sentence for horse-stealing. Dan in 1876 was given three months for aiding a housebreaker; in 1877 six warrants were issued against him for horse-stealing, but he evaded capture.

By 1878 Ned Kelly had formed a gang of thieves, comprising himself, his brother Dan, Steve Hart (a native of Wangaratta born in 1860) and Joe Byrne, born near Beechworth in 1857. In April of that year a constable attempted to arrest Dan at his mother's house, and was shot in the arm by Ned; and on the following day Mrs. Kelly and two neighbours were arrested for attacking the constable, Ned and Dan having concealed themselves in the rough country at the head of the King River. A reward was offered for their apprehension, and for five months the police made an unsuccessful search; but in October when news came that they were in the Wombat hills, parties from Greta and Mansfield set out to surround them, and the gang, coming upon the Mansfield party, shot three policemen. This encounter was decisive. On the one hand the government at once offered £200 for each of them, alive or dead, and increased the reward two days later to £500. On the other hand the bandits, knowing themselves outlawed, began a career of active and desperate crime. The story of the next two years is well known, and may be read in detail in the books named below. It included raids on Euroa (11 December) in Victoria, and Jerilderie (9 February 1879) in New South Wales—at both places the banks were robbed, and Jerilderie was held for three days; after the second raid rewards offered by the governments of Victoria and New South Wales amounted to £8000 in all. Then for 16 months the gang remained quiet. Not all the rewards could induce their friends to betray them, though the police put pressure on those known to favour them, and brought black trackers from Queensland to assist in the search. At last an accomplice named Aaron Sherritt, on the promise that he should receive a clear £4000 of the reward, agreed to lead the police to their hiding-place. On 27 June 1880 he hid a party in his cottage, but Dan Kelly and Byrne had him enticed to the door and shot him; then, knowing that after this outrage a strong force of police would certainly be sent against them, the gang hastened to Glenrowan, where the main railway line crosses a low ridge, took possession of the township, and tore up the rails at the far end of a cutting just where the line runs on to a curved embankment and across a deep ravine. All the male inhabitants of the township, and all strangers who came along, were interned in the local hotel, a few Kelly sympathizers keeping them company.

Meanwhile the authorities in Melbourne had hastily sent off a special train with police and black trackers, which about dusk on the 28th was stopped a little way out of Glenrowan by a schoolmaster who had escaped from the Kellys' custody. Preparations were at once made for an assault on the hotel, and a request for a small cannon was telegraphed back to Melbourne, a 12-pounder Armstrong gun with a detachment of garrison artillery being promptly despatched by train. So exaggerated, indeed, were the official ideas of the gang's strength that it was even proposed to send off an electric search-light to facilitate night attacks. During the evening several of the captives were let go from the hotel, and the affair became a siege; at daybreak reinforcements of police arrived from Wangaratta, the rest of the captives were allowed to leave the hotel, and Ned Kelly—who had got through the police cordon in the darkness and was firing at his assailants from the rear, clad in rough head and body armour—was shot in the legs and captured. In the afternoon of the 29th the hotel building was set on fire, and the bodies of the other three members of the gang were found in the ruins, probably self-slaughtered. The gun-train was therefore held up at Seymour. Ned Kelly was taken to Melbourne, convicted there of the murder of the Mansfield police, and hanged on 11 November. His 'armour,' which was made out of stolen plough mouldboards and weighed nearly 100 lb., is still preserved at police headquarters in Melbourne. A duplicate suit, which was for many years exhibited in the so-called 'convict hulk' *Success*, was made after Kelly's death to be shown in the Melbourne exhibition of 1881. It is on record that the rest of the gang had similar armour, but their suits have disappeared.

The most accurate account of the Kelly gang's doings will be found in Charles White's *History of Australian Bushranging* (1906). Hare's *Last of the Bushrangers* (1892) and Boxall's *History of the Australian Bushrangers* (5th edition, 1924) are also useful.

Kelly, James (1791-1859), born at Parramatta on 24 December 1791, went to sea as a boy and was employed in the whaling and sealing industry. In December 1815 he left Hobart in a whaleboat manned by four men, and circumnavigated Tasmania, discovering Port Davey and Macquarie Harbour; in his narrative of this voyage he gives an account (the only first-hand description available for this early period) of the life of the sealers of Bass Strait and the aboriginal women whom they bought or stole—the ancestors of the so-called half-castes of Bass Strait. In 1817 Kelly was sealing on the New Zealand coast, in command of the schooner *Sophia*, when the Maoris attacked his men at Otago harbour, and killed his brother-in-law William Tucker, who had been the first man to bring to Sydney for sale a dried Maori head (these were in those days sought after by connoisseurs for their tattoo marks). The Maoris then tried to seize the vessel, but the crew (16 against 400, according to Kelly's figures) cleared the deck with their sealing knives. In 1819 Kelly was appointed harbour-master and pilot at the Derwent, became largely interested in whaling, and owned several vessels. In 1832 he took his ship the *Venus* down to 72° S. lat., thus becoming technically the first Australian explorer of Antarctic regions. He died at Hobart on 20 April 1859. His name is preserved in Kelly Basin at the head of Macquarie Harbour.

T.D.

Kemp, ANTHONY FENN (1773-1868), born near Aldgate in London in 1773, and educated at Greenwich, travelled in France and the United States while still a youth, and on 24 July 1793 was commissioned ensign in the New South Wales Corps (lieutenant, 1797; captain, 1801). His early career in the corps was uneventful; in 1795 he took his turn at Norfolk Island, and in 1799 obtained from Hunter a small grant of town land opposite the barracks, where is now the north-eastern corner of George- and King-streets. Here he built a store—for he was a trader at heart, and a successful one during most of his life; a caustic account of the methods by which he contrived to profit commercially by his position as paymaster of his company will be found in the *Memoirs of Joseph Holt*. In 1800-1 he visited England on leave. On 17 September 1802 he was admitted a master mason at the first lodge known to have been assembled in Australia (see FREEMASONRY), by officers of Baudin's expedition: it is curious that within a fortnight he was spreading reports that these very officers were selling liquor illegally to convicts. He was forced to apologize for the slander, and the apology was officially accepted; but, when Governor King a little later suspected Baudin of an attempt to annex southern Tasmania, the French commander at once charged Kemp with being the author of that false rumour also. In January 1803 he was involved in a grave scandal; scurrilous attacks on King were found in his backyard, and the consequent court martial was interfered with by Major Johnston, then commanding the corps, who went so far as to defy King's definite orders in several important respects. In the end Kemp was acquitted, and King was asked by the authorities in London to acquiesce in this verdict for the sake of peace in the colony. In June 1804 Kemp was treasurer of the corps' committee of paymastership, but in the same year King sent him to Port Dalrymple in Tasmania as second in command to Colonel Paterson, and in 1806-7 he administered the settlement for seven months during Paterson's absence in Sydney. Towards the end of 1807 he went back to Sydney on sick leave, and so happened to be the senior officer (after the judge-advocate) of the court martial summoned to try John Macarthur on 25 January 1808; his refusal to sit with Atkins as judge-advocate initiated the Bligh mutiny (see BLIGH, WILLIAM). A strong supporter of Johnston, Kemp was made the mutineers' judge-advocate, was authorized to celebrate civil marriages, and obtained from Foveaux as a reward 24 cows and 500 acres of land. In December 1808 he resigned his judicial position to become commandant at Parramatta, and during 1809 obtained from Paterson a further grant of over 1400 acres. After Macquarie's arrival he was sent to England as a witness for Johnston and remained there until 1815, when, finding that the Paterson grants had been cancelled (though the Johnston grant was confirmed), he obtained leave to settle in Tasmania. Macquarie in 1816 made him a magistrate there, and Davey gave him 800 acres, which he located at Cross Marsh on the road between Hobart and Launceston. Putting his son in charge there, he became a merchant at Hobart, having for some years as a partner George Gatehouse who was afterwards a brewer at New Town. In 1817-19 he was involved in a series of unedifying quarrels with Davey and Sorell: both governors suspended him from the magistracy, and Sorell's action was emphatically confirmed by Macquarie. He gave voluminous and vindictive evidence against Sorell at Bigge's enquiry in 1820, but without convincing Bigge; a few years later, however, in January 1824, he withdrew his previous charges and testified that 'our Personal Rights and the General Security of Property will hardly find a more able and upright Protector than Lieutenant Governor Sorell.' By this time, indeed, he had settled down to a long life of commercial prosperity: he became a director of the Bank of Van Diemen's Land, and a leader both of the Presbyterian Church and of the merchants of Hobart in public movements (e.g. for the introduction of trial by jury and the abolition of press censorship). He died at Sandy Bay near Hobart on 28 November 1868.

Kendall, HENRY (1841-1882), son of Basil Kendall and his wife Melinda McNally (a granddaughter of Leonard McNally of the United Irishmen), was born on 18 April 1841 at Kirmington near Milton in southern New South Wales. His grandfather Thomas Kendall, a Lincolnshire man, was one of the first missionaries to New Zealand, and the first white man commissioned as a magistrate for that country. Arriving there in 1814, he was almost immediately able to compile a Maori-English primer which was printed at Sydney in 1815; in 1820 he accompanied some Maori chiefs to England and joined Professor Lee of Cambridge in writing the first grammar of the Maori language. His son Basil fought in the Chilean navy under Lord Dundonald, but returned to New South Wales and settled near Milton, whence he moved with his family (including the young Henry) to the Clarence River district in 1846. He died there about 1851.

Henry went back for a time to the south coast, and then spent two years (1855-7) as cabin-boy on board a brig of his uncle's that voyaged about the Pacific and up to Japan; this episode in his life, however, he found anything but pleasing. Coming back to Sydney in 1857, he found employment in a draper's shop in Pitt-street, and began to write verse, sending it to *The Australian Home Companion* (which published his first set of verses in 1859 and others in the two following years), the *Empire* (which brought him under the notice of Henry Parkes), and the *Sydney Morning Herald*. He was also brought into contact with J. L. Michael and Nicol D. Stenhouse (q.v.); Michael took him into his office, and carried him up to Grafton when he moved there in 1861. Restless, however, and wholly bent on verse-making, Kendall soon returned to Sydney and set himself to a serious poetical career. In 1862 he sent some poems to the *Cornhill Magazine* (of which Thackeray was editor), and later in the year sent others to the *Athenaeum*; *Cornhill* ignored him, but the *Athenaeum* printed some of the poems and became (and remained) a source of favourable criticism. In October of the same year—before anything was known of the fate of his English ventures—his first volume, *Poems and Songs*, was published at Sydney by J. R. Clarke, and was well reviewed. In August of 1863 Parkes got him a position in the surveyor-general's office, and in 1866 transferred him to his own (the colonial secretary's) department. Kendall took advantage of his easier circumstances to write verse steadily.

In 1868 a prize was offered in Melbourne for the best Australian poem; Kendall sent in three, and the judge—R. H. Horne, q.v.—not only awarded him the prize but said that if there had been three prizes the other two would

have been given to Kendall also. Vastly encouraged, Kendall decided to earn his living as a writer; in 1869 he resigned his official position, moved to Melbourne, and became a member of the coterie that included Marcus Clarke, G. G. McCrae and A. L. Gordon. But the venture was not a success, financially or otherwise. George Robertson, the great Melbourne bookseller of the time, published his second volume, *Leaves From Australian Forests*, and lost £90 over it. Poetical matter was ill-paid and not much wanted. In 1870 Kendall lost his first-born and favourite child, Araluen; he returned to Sydney in 1871, and sank into what he termed 'the shadow of 1872,' from which he was rescued by the devotion of his wife, and kindness of two friends, the Fagans, who in 1873 brought him and his family to their sawmill at Camden Haven. The next seven years were the serenest, and probably the happiest, of his life and produced some of his best poems, 'Orara,' 'Hy-Brasil,' 'Cooranbean,' 'After Many Years.' His third volume, *Songs from the Mountains*, was published in 1880 and made money for him, and he had already won a prize of £100 offered by the *Sydney Morning Herald* for a poem on the Sydney International Exhibition. In 1881 Henry Parkes, who never ceased to admire him, made him inspector of State forests; but exposure attendant on long journeys through the bush broke down his already weak frame, tubercular disease followed, and he died at Redfern on 1 August 1882. He was buried in the Waverley cemetery.

Kendall's work, being voluminous, is naturally unequal, and in a 'collected edition' may be unfairly judged. His attempts to be jocular were usually failures, for he knew little about men; nor was he in reality a close observer of nature. But there is no doubt about the true lyrical cry, the ear for delicately beautiful phrasing, the poignancy of emotion, which all his best work discloses, and the 'September in Australia' and 'Rose Lorraine' of his second volume and the poems already mentioned in his third are permanent possessions. By virtue of this and similar work he was for many years the one Australian poet whom British anthologists admitted on equal terms with British poets; and in the art of pure poetry no Australian writer has yet excelled him.

Kennedy, Sir Arthur Edward (1810-1883), born at Cultra in county Down on 9 April 1810 and educated at Trinity College, Dublin, entered the army in 1827 as ensign in the 27th foot, in 1840 was commissioned captain in the 68th foot, and retired in 1848 to enter the colonial service. In 1846 he had been seconded as poor-law inspector in Ireland, and during the famine served on Sir J. Burgoyne's relief committee. In 1851 he was made governor of Gambia, in 1852 transferred to Sierra Leone, and in 1854 appointed in addition consul-general for the Sherbro district, which at the time was not a part of the colony proper. In 1855 he was again transferred, this time to Western Australia, where he was governor from 23 July 1855 to 17 February 1862. Thence he went to Vancouver Island (1863-7), West Africa (1867-72), and Hong Kong (1872-7), returning to Australia in 1877 as governor of Queensland; it is noteworthy that from 10 April to 20 July of that year he was merely administrator of the Queensland government, as he reached the colony much earlier than did the letters patent constituting him governor. Unassuming and kindly, he served his term without many eventful happenings; but almost his last act was to acquiesce (unofficially) in McIlwraith's daring, illegal, and ineffective annexation of eastern New Guinea to prevent the Germans from taking it. Leaving Brisbane on 2 May 1883, he was on his way back to England when he died at Aden on 3 June. (C.B., 1862; Kt. Bach., 1867; K.C.M.G., 1871; G.C.M.G., 1881.)

Kennedya, a genus of the family Leguminosae, consisting of twining or prostrate shrubs, endemic in Australia. The flowers are red, violet to purple; leaves simple, or divided into three leaflets; pods compressed, with pithy partitions between the seeds—when ripe they burst with

Kennedya monophylla.

considerable violence, thus widely scattering the seeds. *K. monophylla* is the 'false sarsaparilla,' frequently mistaken for the native sarsaparilla (see Smilax). *K. Comptoniana*, a Western Australian species, is a handsome climber with numerous trusses of bright blue flowers; it is easily raised from seeds, and makes a rapid growth.

Kennion, George Wyndham (1845-1922), born on 5 September 1845 at Harrogate in Yorkshire and educated at Eton and at Oriel College, Oxford (B.A., 1867; M.A., 1871), took holy orders in 1869 (priest, 1870) and after two years' service as diocesan inspector of schools was made vicar of St. Paul's, Hull (1873-6) and of All Saints, Bradford (1876-82). In 1882 he was chosen to be bishop of Adelaide, consecrated in November, and reached Adelaide early in 1883. During the next 12 years he greatly developed church organizations and, outside his diocesan work, encouraged the improvement of higher education: from 1887 to 1894 he was an active member of the council of the university. In 1894 he was translated to the

English see of Bath and Wells, and administered that diocese till his death on 19 May 1922.

Kent, THOMAS, of whose history before 1807 nothing is known, in that year determined to migrate to Port Dalrymple. Fortified with recommendations from ex-governor King and the whaling magnate Samuel Enderby (whose name is perpetuated in Enderby Land in the Antarctic), he obtained from the colonial office an order on Governor Bligh for 600 acres of land and the use of six convicts. Reaching Sydney on 27 November 1808 in the ship *Speke*, Kent found Bligh under arrest and unable to help him: he therefore at once went into partnership with a Bengal merchant, J. C. Burton, in a project for growing and manufacturing hemp with the aid of 'twenty native Indians or Chinese,' and Colonel Paterson gave the partners 500 acres near Toongabbie, allowing Kent a separate area of 1230 acres north of Cobbitty. Nothing came of this project, and in January 1810 Kent joined Simeon Lord (q.v.) in a plan for manufacturing cordage in New Zealand from the native flax; Kent was to superintend the industry on the spot, and Macquarie agreed to make him a magistrate for New Zealand. The news of the *Boyd* massacre, however (for which see NEW ZEALAND), scared Kent, and he settled down on his Cobbitty farm. By 1813, however, he had moved to Tasmania, and in February Macquarie warned Davey that he was one of a number of 'designing characters' against whose 'plausible but interested projects and Speculations' the new lieutenant-governor must be on his guard. For the next few years the only records of Kent concern his quarrels with the governing authorities over land, over the price of hay, over the loss of spirits in bond, over the use of convict transports as merchantmen, and in 1817 Macquarie renewed to Sorell the warning he had given to Davey. But Kent's inventive genius was still active, and in April 1819 he submitted to Sorell proposals (*a*) for extracting tannin from wattle-bark, (*b*) for procuring soda from the local seaweeds. Sorell apparently remained uninterested, for Kent went off to Sydney and disposed of his discoveries to Simeon Lord, who sent him back to Tasmania to make up a parcel of tannin and soda and take it to England 'for tryal and sale amongst the manufacturers.' In October Kent approached Bigge on the subject, and in the following March (1820) gave evidence at Bigge's enquiry in Hobart that he had already despatched two tons of tannin extract. Early in 1822 he found it necessary to leave Tasmania hurriedly for England, where he stayed until 1828. In 1824 the Royal Society of Arts granted him 30 guineas for his tannin discoveries, and in 1828 the colonial office (apparently under the impression that he was visiting Australia for the first time) sent him to Sydney with a land-order on Darling for 5000 acres at once and another 5000 as soon as he should have exported 50 tons of wattle extract. But during his absence he had been made bankrupt in the colony, and on arrival his creditors had him gaoled and demanded the 5000 acres from Darling. The governor very wisely insisted on an arrangement, and Kent disappears from history while farming the grant for his creditors' benefit. His discovery, however, was well exploited by others. In 1825 Messrs. Petchey and Wood (the latter probably Patrick Wood of Hobart) received from the Royal Society of Arts a gold medal for their tannin extracts, and between 1831 and 1845 15,516 tons of wattle-bark were shipped to England from Launceston alone.

Kent, WILLIAM (1751-1812), born at Newcastle-on-Tyne in 1751, was a nephew of John Hunter, the second governor of New South Wales. He entered the navy when 12 years of age (midshipman, 1763; lieutenant, 1781; commander, 1802; post-captain, 1806), and went on active service in the Channel and North Sea from 1770 till 1795, when he was given command of H.M.S. *Supply* to accompany his uncle in H.M.S. *Reliance* to New South Wales. The *Supply* reached Port Jackson on 7 September 1795. The *Reliance* and *Supply* were then employed in bringing cattle to the colony, and in 1797 were sent to the Cape of Good Hope for live-stock and stores. While at Cape Town, Waterhouse (who was in command of the *Reliance*) and Kent heard of some pure-bred Spanish sheep for sale, and privately purchased them for the improvement of the flocks in New South Wales. On return to Sydney the *Supply* was condemned as unseaworthy; only Kent's good seamanship had brought her into port. Kent and his crew were then transferred to the *Buffalo*, in which he took Hunter back to England, leaving Sydney on 28 September 1800. King strongly recommended that he should be made lieutenant-governor of Norfolk Island. However, on arrival in England he was reappointed to the *Buffalo*, returned to Sydney on 16 October 1802, and was employed by King in survey work and the bringing of cattle from India; during one of these trips, on 19 May 1803, he discovered Port St. Vincent in New Caledonia. In October 1804 he conveyed Paterson and his party to occupy Port Dalrymple. On 24 May 1805 he was transferred to the *Investigator*, and ordered by King to take her home with despatches; he rounded the Horn in the depth of winter and reached Liverpool on 14 October. In November 1808 he was given command of H.M.S. *Agincourt* and on 26 June 1812 appointed to H.M.S. *Union*, but died at sea off Toulon on 29 August. Kent's letters to Banks (published in the *Historical Records of New South Wales*, vol. iv) show him to have been enterprising and acutely observant. In 1800 he took to England emus and black swans for Banks, as well as specimens of Australian iron ore, and was anxious that the British government should encourage the smelting of ore locally. On leaving Sydney in 1800 he sold his house in George-street to the government at its own valuation, to be used as an orphan institution. The Kent group of islands in Bass Strait was named after him. His only son, born in Sydney in 1799, also served in the navy.

Several of Kent's relatives served in Australian waters. BARTHOLOMEW KENT was in 1805 a lieutenant in the *Buffalo*, and followed his uncle William to the *Investigator*. WILLIAM GEORGE CARLILE KENT, brother of Bartholomew, joined the navy in 1796, served as a midshipman with Sir Sidney Smith in the *Tigre* at the defence of St. Jean d'Acre in 1799, came to New South Wales with his uncle in 1802, was made by King lieutenant of the *Buffalo* in August 1805 and by Bligh lieutenant of the *Porpoise* in January 1807, transferred later in that year to the command of the *Lady Nelson*, and made by Bligh commander of H.M.S. *Porpoise* in March 1808 (after the mutiny); but, as he considered it his duty to obey orders from the *de facto* authorities in Sydney, Bligh on 1 January 1809 dismissed him from the *Porpoise* and put

him under arrest. After 23 months' confinement he was tried by court martial on 8 January 1811, and honourably acquitted.

Besides the three Kents mentioned above (who in 1802-5 were simultaneously commander, lieutenant, and midshipman in the *Buffalo*), RICHARD KENT, a naval surgeon by profession, and not related to the others, was appointed superintendent of convicts aboard the transport *Boddingtons* in 1792 and visited Port Jackson in 1793-4. Grose for some unknown reason describes him as a 'naval agent.' For THOMAS KENT, who also was in no way related to William, see the article under his name. Kent-street in Sydney took its name from none of the five, being named after Edward, Duke of Kent, a son of George III.

Kerferd, GEORGE BRISCOE (1831-1889), born in Liverpool in 1831, migrated to Victoria in 1852, and settled at Beechworth, of which town he was mayor four times in succession. In 1867 he was called to the Victorian bar. In 1864 he was elected to the legislative assembly as member for the Ovens. In June 1872 he joined the Francis ministry as solicitor-general, became attorney-general in May 1874, and at the end of July succeeded Francis in the premiership, taking in James Service as his treasurer. A year later he resigned, but was attorney-general in the McCulloch ministry of 1875-7 and the Service ministries of 1880 and 1883-6. While out of office in 1877-80 he helped to compile a digest of supreme court decisions between 1846 and 1871. In 1883 he represented his colony at the intercolonial conference that originated a federal council. In January 1886 he was raised to the supreme court bench—an appointment that was much criticized by the profession but warmly approved by politicians. The criticism he soon lived down, and his best-known decision as a judge—when he concurred with Chief Justice Higinbotham in upholding the right of any colony to impose what conditions it chose on the admission of aliens—though overruled by a majority of the court (Ah Toy *v.* Musgrove), was upheld on appeal by the privy council. He died on 31 December 1889.

Kestrel. See HAWKS.

Kidston, WILLIAM (1849-1919), born at Falkirk, Scotland, in August 1849, educated at Falkirk, and trained to be a machine-fitter, in 1882 migrated to Sydney and soon afterwards went to Rockhampton in Queensland, where he became a bookseller. In 1893 he contested Rockhampton in the Labour interest, and was defeated, but in 1896 was returned at the head of the poll. Re-elected in March 1899, he was from 1 to 7 December 1899 treasurer and postmaster-general in the short-lived Dawson ministry. From 1900 onwards he was leader of the opposition, and on 17 September 1903 became treasurer in the Morgan ministry at the head of the Labour section in that coalition. He soon established a reputation both for ability and for strength, and his grasp of public finance ensured that, when in January 1906 Morgan resigned office, he should be the inevitable successor. In his first ministry (1906-7) he was premier, chief secretary, treasurer, and vice-president of the executive council. At the general election of 1907 he dissociated himself from the Labour party, but was again returned for Rockhampton; on 19 November he resigned the premiership and was succeeded by Robert Philp, but on 18 February 1908 returned to office as premier, chief secretary, and vice-president of the executive council; and in 1909 formed a coalition with the remains of Philp's party. On 7 February 1911 he retired from politics and soon afterwards was appointed a member of the land court. He died on 25 October 1919.

Kidston's legislative record was not large, though he had to his credit the university act of 1909, the mining on private lands act of the same year, a good deal of land legislation in 1906-10 which was mainly the work of J. T. Bell (see BELL, SIR J. P.), and the constitutional reforms of 1908 that severely limited the power of the legislative council and prepared the way for its abolition in 1922. But he was a strong administrator, especially of the treasury, and during his premiership restored the State's finances to a thoroughly healthy condition; his opinion on financial matters was also valued highly in inter-State conferences. Probably his most important contribution to the welfare of his State was his conception of the great railway scheme, now (1925) half completed, whereby Queensland is to be gridironed by two parallel lines, from Thargomindah to Camooweal on the west and from Brisbane to Cairns in the east, with four crossbars through Cunnamulla, Roma, Longreach, and Hughenden.

Killer. See WHALES.

Kinchela, JOHN, a lawyer who had been in the public service in the West Indies and recorder of Kilkenny, was in July 1830 appointed attorney-general of New South Wales and reached the colony in June 1831; he was immediately appointed to the legislative council, and held his seat there until November 1837. Unfortunately he was so deaf that Bourke in 1832 declared him 'nearly incapable of getting through the business required of him'—and suggested that he should be made a puisne judge in Tasmania. In August 1833 J. H. Plunkett, then solicitor-general, was deputed to relieve him of all work in court. For the next few years he was continually being harassed by the demands of his creditors in England, and it became apparent that he had been given the appointment in New South Wales in the hope that he would be able to save money and discharge a load of debt. In 1835 Bourke again called attention to the evils arising from Kinchela's deafness, and in February 1836 the colonial office at last decided to retire him, giving him the first vacant office in which deafness would not be detrimental. Bourke meanwhile gave him in April an acting puisne judgeship (due to the absence of chief justice Forbes on leave), apparently considering deafness no defect in a judge (Kinchela had been deaf, he explained, while recorder of Kilkenny without harmful results). Bourke's persistence is rather remarkable. In December 1836 he again suggested making Kinchela a puisne judge in Tasmania; in June 1837 he proposed him as a fourth (equity) judge in New South Wales. But the colonial office stood firm in its belief that deafness was a disqualification for the bench, and suggested a pension of £500 a year. At the moment when this proposal was laid before the legislative council (October 1838) the granting of pensions was disfavoured, and Gipps evaded the difficulty by making Kinchela 'advising counsel to the government' with a salary of £500. This practically honorary position he retained until his death on 21 January 1845. In 1840 Gipps also made him commissary of the vice-admiralty court. On 2 September of that year his son took occasion to horsewhip James Mudie, who in his *Felonry of New South*

Wales had attacked the father; when the matter came into court, the jury awarded Mudie £50, 'being one pound for every blow the plaintiff had received,'—and the amount was raised at once by public subscription.

King, JAMES, usually known as James King of Irrawang, migrated to New South Wales in 1826, and on reaching the colony in 1827 obtained a grant of about 2000 acres on the Williams River near Raymond Terrace. Here he grew grain and raised cattle, but his main business—that of a merchant—he carried on simultaneously in Sydney. In 1831 he discovered between Sydney and Botany Bay a deposit of 'fine white sand . . . better suited for the manufacture of fine plate and flint glass than any found in England.' English glass-makers reported very favourably on the sand, and King demanded as reward 50 acres of either 'Goose Farm' (i.e. Grose Farm, now the site of the university of Sydney) or the Sydney Domain. In 1833 the executive council, at the suggestion of the colonial office, granted him a remission of £100 on the price of any land he might desire to purchase, but refused any further reward. In 1834 it was found that the cost of carrying the sand to England was almost prohibitive, but the potential value of King's discovery was recognized by the gift of the silver medal of the Society of Arts. Unable to obtain further recognition, he seems to have dropped the sand enterprise, settled down at his Williams River estate (which he named Irrawang), and divided his attention between grape-growing and pottery works. In 1838 he was selling good earthenware in Sydney. His development of the wine-making industry became important. In 1832 he planted his first vineyard, and in February 1836 made wine from its grapes: his vines came from Spain, Portugal, and France, a shipment from Rhine vineyards having proved a failure. His white wines are described as resembling hock or sauterne: his red wine was a burgundy. In 1850 the Horticultural Society of Sydney gave him its gold medal for light sparkling wines and white wines, and at the Paris exhibition of 1854 he was also awarded a medal, and his wine was served at the emperor's table. Some years earlier his work had attracted the notice of Baron von Liebig, who warmly approved of his provisional blendings and other experiments in wine-making. When in 1855 King visited Europe, he spent some time with von Liebig at Munich, met the grand duke of Nassau, and was told that his best red wines equalled the produce of the famous Assmannshausen vineyards. In 1857 he printed in Edinburgh for private circulation *Australia may be an Extensive Wine-growing Country.* Ill-health prevented him from returning to New South Wales.

In 1888 William Roberts of Penrith, who had married King's widow, left to the university of Sydney £4000 to found a scholarship in memory of James King: this is awarded biennially to enable the holder to study in Europe or the United States, and already several winners of it have become professors in Australian universities.

King, PHILIP GIDLEY (1758-1808), born at Launceston in Cornwall on 23 April 1758 and rated midshipman in H.M.S. *Swallow* in 1770 (lieutenant, 1778; commander, 1791; captain, 1800), during the following 13 years served in East Indian, North American, and home waters, and in January 1783 was appointed to H.M.S. *Europe,* then commanded by Arthur Phillip. Phillip strongly favoured the young officer, and when given charge of the expedition to Botany Bay in 1786 took King with him in the *Sirius* (see FIRST FLEET) and then in the *Supply.* A few days after landing King was chosen—probably as a fluent French scholar—to call officially on La Pérouse. On 1 February 1788 Phillip appointed him superintendent and commandant of the settlement to be established at Norfolk Island, and on the 15th he embarked with a small company of 23 (including 9 male and 6 female convicts), and reached his destination on 6 March. Apart from administering justice in the little community and receiving the newcomers sent over by Phillip, his chief work lay in cultivating the soil and fostering the increase of the introduced stock. In March 1790 he was recalled by Phillip to carry despatches to England, and so missed the mail bearing his commission as lieutenant-governor of Norfolk Island —a promotion recommended by Phillip even before he received King's first report. After three months in London he returned to his duties on 4 November 1791, and complained at once of the inefficiency of Major Ross, who had been in charge during his absence. The population now numbered 1000, but by 1793, thanks to King's care, they were independent of grain supplies from Sydney; in the following year the importation of animal food ceased, and after that date the surplus of foodstuffs allowed of an increasing exportation. When Phillip retired, King found himself the subordinate of Major Grose of the New South Wales Corps, and friction with the military authorities ensued; in 1793 members of the island garrison caused disturbances among the convicts, as a result of which the soldiers mutinied, some of them being sent later on to Sydney for trial. King was granted sick-leave in August 1796 and arrived in England on 6 May 1797. His prospects at the time were not bright, and his request for promotion to the rank of post-captain was refused. Banks, however, stood his friend and obtained for him a dormant commission as governor of New South Wales in the event of the death or absence of Governor Hunter; but the commission was limited in scope, and the titles of captain-general and governor-in-chief were withheld. The re-embarkation of King and his family was delayed until the departure of the transport *Speedy* on 26 November 1799, when the letter recalling Hunter was also despatched. The recall was not urgent, and Hunter retained his office until 28 September 1800, despite strained relations with King, who was waiting to take over the government. King was provided with no written instructions (save those he borrowed from Hunter) until 1802, when they were forwarded together with his full commission as captain-general and governor-in-chief of New South Wales.

The officers of the New South Wales Corps had continually opposed Hunter, and were no more friendly with King. John Macarthur (q.v.) tried to arrange a boycott of the governor; when his superior officer, Paterson, opposed it, Macarthur met him in a duel in which Paterson was severely wounded. King thereupon sent Macarthur to England for trial, but the British military authorities insisted that he should be tried in the colony, and Macarthur solved the difficulty by resigning his commission and returning to New South Wales as a civilian—a position in which he could give King more trouble than ever. Further friction with the Corps was caused by a charge made by Anthony Fenn Kemp, one of its officers, against officers of

the French expedition under Baudin; this, after some acrimonious correspondence between King and Paterson, had to be withdrawn. The governor himself, too, suffered from malicious libels (see PIPES) circulated if not originated by officers of the Corps: King ordered the holding of courts martial on the offenders, and in the quarrel that ensued much petty vindictiveness was shown on both sides. Possibly the large number of pardons to convicts granted by King (78 per annum, as against Hunter's 36) may be explained by his desire to build up a strong class of emancipists as a counterpoise to military domination.

It was in this atmosphere of mutual hostility that King had to administer the colony. One of his first acts was to announce to the officers, civil and military, that all manner of traffic carried on by persons bearing the king's commission was strictly forbidden. Thereafter he made spasmodic efforts to control the liquor traffic by sending away cargoes brought to port, but without much success. The general trading monopoly enjoyed for so long by the officers was limited, however, by an extension of the system originated under Hunter of selling necessary articles at a fixed price from the public store, and also by the development of legitimate private trade, mainly by Robert Campbell (q.v.) and William Tough. As a result the excessive price of the necessaries of life declined, agriculture revived, and the number of people supporting themselves without government assistance increased from 1635 on 28 September 1800 to 3747 on 3 October 1802, the number victualled from the public store remaining stationary. The regular despatch of supplies from England also enabled King to reduce the amount of bills drawn on the British treasury, and he effected further economies by promoting the cultivation of public land and the manufacture of linen and wool, by regulating the currency (q.v.), and by instituting a quarterly settlement of government accounts.

During the whole of King's term of office the colony was disturbed by the presence of the disaffected Irish prisoners (see IRISH EXILES). Their first conspiracy to overthrow the government was abortive, but a second attempt in 1804 resulted in open rebellion, which was crushed by the prompt action of the governor and of Major George Johnston. In order to remove the Irish leaders from contact with the general community King reoccupied Newcastle on the Hunter River, which had been temporarily settled in 1803, and so further extended the area of his active jurisdiction. This had already been increased by a settlement on the Derwent River under Lieutenant John Bowen (q.v.) and a later one on the Tamar by Lieutenant-colonel Paterson. King Island in Bass Strait was occupied by Lieutenant Robbins to forestall a suspected annexation by Baudin. Meanwhile the abandonment of Norfolk Island had been officially decided on—but it took a number of years to remove all the settlers. The original settlement at Port Jackson was extending coastwise, the Blue Mountains still presenting an effective barrier to inland development. King was interested in exploration, and in 1801 despatched Lieutenant John Murray on the voyage that resulted in the discovery of Port Phillip; later in the year he sent Lieutenant James Grant to examine the Hunter River; he also prepared the first fully equipped party for land exploration under Ensign Barrallier. Among other useful measures he in 1803 allowed George Howe, the government printer, to publish weekly the *Sydney Gazette*, 'it being desirable that the settlers and inhabitants at large should be benefited by useful information being dispersed among them;' he also established a much-needed orphans' institute, and endowed it with a grant of land. His advocacy of judicial reforms was unheeded by the colonial office. In his public acts King was as a rule undoubtedly disinterested, though in one or two cases—notably in respect of certain land grants made by him to his successor, Bligh, and by Bligh to him—his powers were certainly used for the benefit of his family. His constant quarrels with the military, and their consequent attacks on him in letters to England, induced him as early as May 1803 to apply for leave to retire; but, though Lord Hobart in November of the same year gave him the required leave, it took so long to choose a capable successor that it was not until August 1806 that he was able to resign. Bligh took over on 13 August, and King, assuming command of H.M.S. *Buffalo*, sailed for England via Cape Horn on 10 February 1807, but did not reach his destination until November. Severe attacks of gout broke down his health completely, and he died at Tooting near London on 3 September 1808.

King, PHILLIP PARKER (1791-1856), born on 13 December 1791, while his father Philip Gidley King was in command at Norfolk Island, entered the navy in November 1807 (midshipman, 1808; lieutenant, 1814; commander, 1821; post-captain, 1830; rear-admiral, 1855), served in the *Diana* on the French coast—where he was commended for gallantry—and in the *Hibernia*, *Centaur*, and *Cumberland* in the Mediterranean until the close of 1811. During the next six years he was in the *Adamant*, *Armada*, *Caledonia* (Sir Edward Pellew's flagship), *Trident*, and *Elizabeth* (the flagship at Gibraltar in 1814), and in February 1817 was selected to carry out a survey of those parts of the Australian coast which Flinders had been compelled to leave unsurveyed. This survey, which is described under EXPLORATION BY SEA, lasted from December 1817 to April 1822; King returned to England in April 1823, worked up his charts, and published his *Narrative of the Survey of the Intertropical and Western Coasts of Australia* in 1827. In September 1825 he was appointed to the sloop *Adventure* for survey work on the south coast of South America, the *Beagle* aiding him. During his absence from Australia he was in 1829 nominated to the New South Wales legislative council, but the appointment lapsed because he could not take his seat within the year. On the return of the *Adventure* in November 1830 he went on half-pay, and in 1831 took up his residence in New South Wales. On 12 February 1839 Gipps appointed him to the legislative council, but on 8 April he became managing commissioner of the Australian Agricultural Company (q.v.), and at once offered to resign his seat in the council; Gipps referred the matter to London, and the resignation was accepted in October. At the end of 1849, the Australian Agricultural Company having abolished the office of commissioner, King retired to his own estate. In May 1850 he was nominated to the council, and in September 1851 was elected to it as member for Gloucester and Macquarie counties. He died on 26 February 1856.—His son, PHILIP GIDLEY KING (1817-1904), born at Parramatta in 1817, served in the *Adventure* and afterwards in the *Beagle* under Robert Fitzroy, but in 1836 left the navy and in 1839 joined his father in the

service of the Australian Agricultural Company. In 1851 he was made superintendent of stock at Port Stephens, and in 1853 manager of the Peel River Company's estates on the Liverpool plains. In December 1880 he was nominated to the legislative council of New South Wales. He died on 5 August 1904.

It should be noted that, whereas Governor King and his grandson were both christened 'Philip,' P. P. King the explorer was christened 'Phillip' because of his father's great admiration for the governor of that name.

King, WILLIAM FRANCIS (1807-1874), born in London in March 1807, was the son of Francis King, paymaster of petty accounts at Whitehall. He was educated for the church, but preferred other work, entered a stockbroking firm, and later on became a clerk in the treasury office at the Tower of London. In 1829 he migrated to New South Wales, bringing credentials to Bishop Broughton who appointed him schoolmaster and clerk at Sutton Forest. Tiring of this work, he for several years acted as a tutor, and then drifted to Sydney, where he worked as a pieman and a hotel barman. His chief means of support, however, was an allowance made by his father. His well-known nickname, 'The Flying Pieman,' was acquired by a remarkable series of walking feats, one of the first being a walk of 1634 miles in 5 weeks and 4 days, for his own gratification. On two occasions he beat the coach from Windsor to Sydney (34 miles) by several minutes; he walked from Sydney to Parramatta (15 miles) and back twice a day for six consecutive days, and on three consecutive days from St. John's church at Parramatta to St. Matthew's at Windsor and back —a distance of 43½ miles; on the first day he took 8 hours, on the second 7½ hours, on the third 7 hours 25 minutes. Among many other feats he carried a dog weighing 70lb. from Campbelltown to Sydney (33 miles) between 12.30 a.m. and 8.40 a.m.—20 minutes over the wagered time—and a live goat weighing 92lb. from Talbot's inn on Brickfield Hill to Andrew Nash's Woolpack inn at Parramatta in 7 hours. He died on 12 August 1874 in the Liverpool asylum for old men.

Kingfish, a name applied in New South Wales and Queensland to a species (*Seriola grandis*) of the trevally family. In the southern States a very different fish, *Sciaena antarctica* (see JEWFISH), is called 'kingfish;' in Queensland the name is also used for *Scomberomorus* (see MACKERELS); the Tasmanian kingfish (*Jor-*

Seriola grandis.

danidia solandri) is a barracouta (q.v.). Many species of *Seriola* occur in all temperate and tropical seas, and several are known from the coasts of Australia. *S. grandis*, which may reach a length of six feet, is plentiful at certain seasons, and provides good sport for rod-fishermen. It usually moves in shoals, and may be taken wholesale in nets; but its flesh is apt to deteriorate rapidly in warm weather, so that as a marketable fish it does not find favour. The allied Samson-fish (*S. hippos*) is so far known only from the coast of New South Wales; it reaches a length of two feet, and is usually captured in the open sea, only young specimens entering inlets.

A.R.McC.

Kingfishers and Bee-eaters, brilliantly plumaged birds with long beaks, that feed on small fish, reptiles and insects and lay white eggs in holes in trees or in the ground. The true kingfishers (Alcedinidae) are represented in Australia by only two species, of which the Blue Kingfisher (*Alcyone azurea*) is the more familiar. This bird frequents the shores of rivers and creeks throughout northern and eastern Australia and Tasmania, and is generally seen perching on an overhanging branch, from which it plunges into the water after small fish.

The forest kingfishers (Dacelonidae) are better

Kookaburra.

represented, Australia possessing eight species. These birds are much less aquatic than the true kingfishers, many being found far from water and feeding on small reptiles and insects. By far the best-known is the Laughing Jackass or Kookaburra (*Dacelo gigas*). This familiar bird is naturally peculiar to eastern Australia, but has been introduced and established in south-western Australia and Tasmania. It was first figured and described in Sonnerat's *Voyage to New Guinea*, published in 1776, and was supposed to have come from that country. The bird frequents open forest country, and is sociable in habits. Its extraordinary laughing note, per-

haps the most familiar sound in the bush, may be heard at all times of the day, but especially at morning and evening; then one bird will begin and all the others in the neighbourhood chime in, till the bush resounds with wild, infectious merriment, 'a chorus of wild spirits' as Sturt called it. The Blue-winged Kookaburra (*Dacelo leachi*) of northern Australia and New Guinea has more colour in its plumage, and an entirely different call.

Other familiar members of this family are the Sacred Kingfisher (*Halcyon sanctus*) found

Forest Kingfisher.

throughout Australia and in many of the adjacent Pacific islands, and the Macleay or Forest Kingfisher (*Halcyon macleayi*) of northern and eastern Australia and New Guinea. All these kingfishers, including the kookaburra, are fond of making their nesting holes in the arboreal nests of termites, though in localities where these do not occur a hole in a tree is adopted. In order to excavate a hole in the very hard substance of the white-ants' nest, the birds fly straight at it from the nearest convenient branch, driving their stout wedge-shaped bills into the selected spot. These tactics are repeated again and again for days in succession, until the hole is large enough for their purpose. The kookaburra, being larger than its allies, adds to its diet lizards and snakes of

Bee-eater.

considerable size, as well as mice, rats and small birds, and sometimes even takes considerable numbers of chickens and ducklings; but its jovial laughter and its reputation for destroying snakes have made it a general favourite, and it is almost universally protected.

The Australian Bee-eater (*Merops ornatus*) is our sole representative of the family Meropidae, found throughout the warmer regions of the eastern hemisphere. Its brilliant plumage, in which blue, green and orange predominate, has earned it in some districts the name of rainbow-bird. Throughout the greater part of Australia it is a summer visitor, laying its white eggs in a hole in sandy ground. A number of pairs usually excavate their burrows close together. In autumn most of our bee-eaters pass northwards to the Malay Archipelago, though some remain in the northern parts of the continent. The bee-eater feeds on all sorts of insects, catching them on the wing, and is by no means restricted to a diet of bees, as its name would seem to imply. W.B.A.

Kingsley, HENRY (1830-1876), younger brother of Charles Kingsley the preacher and novelist, was born on 2 January 1830 at Barnack in Northamptonshire and educated at King's College, London, and Worcester College, Oxford. Before taking his degree he migrated to Victoria in 1853 to work on the goldfields, but had no luck there and drifted to the Western District of Victoria, where he stayed with William Mitchell of Langawilli and wrote his first novel, *Geoffry Hamlyn*, borrowing many of his names from the region between Geelong and Skipton. In 1858 he returned to England, published the novel in 1859, and followed it up with a series of eight (published between 1862 and 1871) of which the best and probably best-known is the first, *Ravenshoe*. Only in one of them, *The Hillyars and the Burtons* (1865) did he again use his Australian knowledge, and then not so much his actual experiences as the tales of other regions he had picked up. In 1870 he was a war-correspondent during the Franco-German war, and was the first Englishman into Sedan after the surrender; the strenuous occupation seems to have sapped his energies, and his later work betrays the strain. He died at Cuckfield in Sussex on 24 May 1876.

Henry Kingsley's writings, while less popular than those of his brother Charles, are by good critics ranked above them. In *Geoffry Hamlyn* he preserved a valuable record of the golden age of squatterdom, before the gold discoveries brought in an excitable and cosmopolitan crowd —and the record is contemporaneous, for no swarms from the Ballarat ant-heap had during the fifties found their way south of Skipton. Kingsley's work is a useful reminder that the settlement of Australia is not entirely bound up with convicts and drought-maimed explorers and the constitutional troubles of New South Wales governors.

Kingston, CHARLES CAMERON (1850-1908), younger son of Sir G. S. Kingston (q.v.), was born in Adelaide on 22 October 1850, educated locally, trained for the law, and admitted to the South Australian bar in 1873. He had served his articles in the office of S. J. Way (q.v.), with whom he stayed until Way became chief justice; he then practised on his own ac-

count, and in 1889 became a Q.C. Meanwhile he determined to enter politics, and was in 1881 elected to the assembly from West Adelaide, which constituency he represented until he left State politics in 1900. He soon came to the front, being attorney-general in the Colton (1884-5) and Playford (1887-9) ministries, chief secretary in the second Playford ministry (1892-3), and on 16 June in the last-named year forming a ministry in which he kept the premiership until 1899—a remarkable feat in a colony where no previous ministry had lasted more than three years, and the average duration had been less than 11 months.

Kingston was an 'advanced liberal;' his programme, almost the whole of which he carried out, included woman suffrage, generous factory legislation, 'progressive' taxation of land, incomes, and inherited wealth, industrial conciliation, a protective tariff, payment of members, and the establishment of a state bank. Being an excellent parliamentary draftsman, he constructed most of his own legislation, and saw to it that the intention was clear and was carried into effect. He was a strong opponent of non-European immigration, and consequently an early advocate of federation. In 1888 he persuaded the South Australian parliament to authorize the appointment of representatives on the federal council, though for two years only; he represented the colony on that council, and at the federal conventions of 1891 and 1897-8; he drafted the enabling bill by which the latter convention was made possible, presided over the convention itself, and took part both in the premiers' conference that gave the federal constitution what was practically its final shape and in the London negotiations which ensured the approval of the Imperial parliament. In 1901 South Australia returned him at the head of the poll to the house of representatives, and he became minister for trade and customs in the first (the Barton) federal ministry; he carried through the house a protective tariff which, though mild in comparison with those of more recent years, occasioned more bitter contests than any of them; and he attempted to persuade his colleagues to adopt a somewhat drastic arbitration bill, which would have extended federal control over the railways of the States. Resigning on this point, he was expected to become the next prime minister and leader of a labour-liberal coalition; but his health began to fail at the critical moment, and—though Adelaide re-elected him without a contest in 1903 and 1906—he gradually withdrew from active politics. He died at Adelaide on 11 May 1908. (P.C., 1897.)

Kingston, Sir George Strickland (1807-1880), born in England in 1807, was trained for the profession of land-surveying, and in 1836 was made assistant-surveyor and second in command to Colonel Light for the first settling of South Australia. He reached Nepean Bay in Kangaroo Island on 11 September, was sent on to Holdfast Bay early in November, discovered and traced the Torrens up and down, and pitched his camp on the site of Adelaide. Dissensions arising between Hindmarsh the governor and Light the surveyor-general, Kingston was sent back to England with despatches, and returned in 1838 with orders to supersede Light unless he quickened up his surveys; Light resented the order and resigned, and Kingston held the surveyor-generalship until the arrival of Charles Sturt (q.v.). In 1839 he was made inspector of public works, and in 1840 town surveyor. Holding aloof as a rule from local politics, he persistently opposed state aid to religion and took an active part in the 1845 protests against the introduction of convict labour. In 1849 he worked hard for the grant of responsible government, and was elected in 1851 to the enlarged legislative council as member for the Burra. In the debates of November 1855 on the details of the new constitution he threw his influence in favour of universal suffrage and vote by ballot, and forced the government to adopt them at least for the house of assembly. In the new legislature he was re-elected for the Burra, and was made speaker; losing his seat at the election of 1860, he remained out of politics for two years, but in 1863 was again returned for the Burra and in 1865 again made speaker, a position which he retained until his death. In 1880, while on a voyage to Ceylon for the benefit of his health, he was taken ill at sea and died on 26 November. (Kt. Bach., 1870.)

Kintore, Earl of. Sir Algernon Hawkins Thomond Keith-Falconer, 10th earl of Kintore, was born at Edinburgh on 12 August 1852, educated at Eton and Cambridge (B.A., 1874; M.A., 1877), and succeeded his father, the 9th earl, in 1880. From 1885 to 1889 he held minor appointments in the house of lords and about the court, and in the latter year was appointed governor of South Australia. During his term of office he took an active interest in the federal convention of 1891 and in the extension of the Oodnadatta railway northwards across the continent. Resigning the governorship on 10 April 1895, he returned to England and resumed the post of lord-in-waiting at the court, which he held until 1905. In 1913 he was made deputy-speaker of the house of lords. His court duties brought him decorations from Italy, Prussia, Portugal, and Sweden. (P.C., 1886; G.C.M.G., 1889.)

Kite. See Hawks.

Knibbs, Sir George Handley, born in Sydney on 13 June 1858 and educated as a surveyor, in 1877 joined the staff of the New South Wales survey department, and in 1889 was appointed to a lectureship in surveying and allied subjects in the university of Sydney. Nominally holding this (the P. N. Russell) lectureship until 1905, he was in 1902 despatched by the New South Wales government to the United Kingdom, continental Europe, Canada, and the United States to report on all branches of education. Shortly after his return he was appointed director of technical education (1905-6), and was also acting professor of physics at the university. He resigned his posts in 1906 to become Commonwealth statistician, and proceeded to create a statistical department whose efficiency has not been excelled elsewhere, and to issue a series of fourteen *Official Year Books* which are renowned the world over; he was also adviser to the federal government on many details of taxation, and devised the mathematical formulae which control Australian land- and income-tax rates. In 1921 he resigned the statisticianship, and became director of the Commonwealth Institute of Science and Industry (q.v.).

Apart from his work as lecturer and statistician, Knibbs has interested himself in many branches of science and many public questions. For nine years he was honorary secretary of the Royal Society of New South Wales, and its president in 1898-9. Over the Institution of Surveyors he presided for four years (1892-3

and 1900-1), over the Society for Child Study for three years (1903-5), and over the British Astronomical Society's New South Wales branch for two years (1897-8). He represented the Australian government at five international congresses, and at two Imperial conferences (on double income-tax and on statistical methods), and has been a member of royal commissions on insurance (1909-10) and taxation of crown leaseholds (1918-9); of the last-named he was chairman. During the war he was also a member of a royal commission on trade and industry and a consulting member of a committee on munitions, and carried out a war-census of persons fit for war-service, and another of the wealth of the Australian people.

He is a member of the Institut International de Statistique, an honorary member of the Societé de Statistique de Paris and of the American Statistical Association, an honorary fellow of the Royal Statistical Society, and a fellow of the Royal Astronomical Society. While at the university he put forth 36 pamphlets on physical, mathematical, engineering, and astronomical subjects, and in his later years a very large monograph on the mathematical theory of population and one on the census of wealth. He has also published two volumes of poems. (C.M.G., 1911; Kt. Bach., 1923.)

Knopwood, ROBERT (1761-1838), born in Norfolk, England, on 2 June 1761 and educated at Bury St. Edmunds and Caius College, Cambridge (M.A., 1784) inherited a large estate, but squandered it in his youth while the associate of Lord Claremont and other riotous livers of the late 18th century. He took holy orders while still young, but did not take them seriously; when, however, it became necessary to earn a living, he found himself qualified to be domestic chaplain to Earl Spencer, who was first lord of the admiralty from 1794 to 1801. In 1801-2 he was chaplain in H.M.S. *Resolution*. Towards the end of 1802 the British government decided to send an expedition to occupy Port Phillip, and put David Collins (q.v.) in charge of it; on 14 January 1803 Knopwood was commissioned chaplain to the expedition, sailed with Collins in the *Calcutta* on 27 April, and became one of his most valued officers both at Port Phillip and (when the settlement there was abandoned and the personnel removed to Tasmania) at Hobart. On 23 October he conducted the first religious service held on the soil of Victoria. As the *Calcutta* had reached the bay on the 9th, services had probably been already held aboard ship within the boundaries of Port Phillip, but this is the first recorded on land; it was held in front of Collins's camp on 'Sullivan Cove,' a little E. of Sorrento, and the convicts were ordered to attend it 'as clean as their present situation will admit.' On 15 February 1804 Knopwood reached Storm Bay, and on the 26th held his first services at the Tasmanian 'Sullivan Cove' in the morning and at Risdon in the afternoon. Being not only a minister of religion but also a commissioned official, he was appointed a magistrate both of the short-lived Port Phillip settlement and of that at Hobart, and (like his greater colleague Marsden) occasioned some scandal among pious settlers by devoting more attention to his civil than to his religious duties. His life in Tasmania (as well as his voyagings from 1801 onwards) is described in some detail by himself in a journal now in the Mitchell Library, of which a portion is to be found in Shillinglaw's *Historical Records of Port Phillip* (1879). As might have been expected from his antecedents, he soon gained the reputation of an unconventional 'good fellow,' full of sympathy and fond of wine—a type of clergyman well known in England in those days, but more conspicuous in a small and censorious community. Collins liked him well, and in 1809 officially commended 'his attention to the duties of his Office, and the readiness with which he has at all times assisted me in his Civil capacity as a Magistrate;' but Macquarie could not abide his unconventionality, suspected that it connoted loose living, and directed Davey (of all men!) to admonish him severely for any impropriety of conduct. Davey used him as an intermediary with Michael Howe's gang of bushrangers; and Sorell, when he succeeded Davey, found on record an 'extraordinary implication' against Knopwood made by Howe, charging him with complicity in their acts. Though absolutely acquitted of this charge, Knopwood felt it deeply, and his health broke down under it; Davey on 10 January 1817 reported his 'long and continued indisposition,' and Macquarie in transmitting the report to Bathurst described him as 'quite superannuated and infirm' and doing more harm than good at Hobart. In 1821, however, the bitter feeling had somewhat abated, and Macquarie recommended that he be allowed to retire on full pay—which was, after all, only 10s. per day. Bathurst refused full pay, but allowed him £100 a year and a grant of land. On 27 April 1823 Knopwood preached his last sermon in old St. David's (which was built in 1817-8), and retired to his grant of land at Rokeby on Ralph Bay, across the Derwent from Hobart. He continued unofficially to meet the religious needs of the neighbouring settlers, until on 4 March 1826 he was officially appointed to the parish of Clarence Plains (i.e. the district in which he was living). He died on 18 September 1838.

Knot. See WADERS.

Koala, often called 'native bear,' is an aberrant species (*Phascolarctus cinereus*) of the phalanger family (see OPOSSUMS), the only representative of its genus and sub-family. It ranges all over eastern Australia from Queensland to Victoria. It is a much larger animal than any of its nearest relatives, the true phalangers, having a length of about 42 inches; and it differs from them most conspicuously in the thickset body, the broad short muzzle, and the absence of a tail. The fur is thick and woolly, grey above, becoming yellowish-white on the hind-quarters, white or yellowish-white below. The ears are large and rounded, thickly covered with hairs, which on the backs are black tipped with white, white elsewhere. Both pairs of limbs are stout; the fore-limb has the five digits sub-equal, the first and second opposable to the other three, all with powerful pointed claws; the hind-limb has the first toe nailless and opposable, and the second and third syndactylous as in the rest of the family. There is a large glandular patch on the chest.

The koala is essentially an arboreal animal, and its movements when it descends to the ground are awkward and clumsy. The grasping power of its hands and feet, with their strong curved and pointed claws, enables it to climb with great sureness; even when severely wounded, it will not readily relax its hold. Mainly nocturnal, it may sometimes be seen moving about in the daytime, but usually passes the hours of daylight asleep in a fork or in the interior of a hollow trunk. Its food consists almost exclus-

ively of eucalyptus leaves, but it descends occasionally in search of other vegetation or to dig for certain roots; cheek-pouches serve for the temporary storage of food. Koalas usually live

Native Bear (Koala).

in pairs. Only one young one is produced at a birth; as in other marsupials, this is very small at first, and is retained in the pouch; when it becomes able to leave this shelter, it is carried about for some time clinging to its mother's back or shoulder. See MARSUPIALS. W. A. H.

Koel. See CUCKOOS.

Kookaburra. See KINGFISHERS AND BEE-EATERS.

Krefft, JOHANN LUDWIG GERHARD (1830-1880), born at Brunswick in Germany, at the age of 15 became a clerk in a large business house at Halberstadt, but, showing great taste for drawing and painting, in 1850 gave up commerce and went to the United States, where he was employed as a clerk and draughtsman. Having studied the illustrated works of Audubon in the New York mercantile library, he copied some of the plates, and by selling them obtained sufficient money to come to Australia. He landed in Melbourne in 1852, and worked on the goldfields until 1857. In 1858 he was selected as painter and naturalist to accompany a collecting expedition organized by the Victorian government; of this he became leader, and brought back to Melbourne a large number of botanical specimens and a well-filled sketch-book—in consequence of which he was made by Professor McCoy an assistant in the Melbourne museum. Almost immediately, however, he revisited Germany and, making a short stay in South Africa on his way back, in 1860 settled in Sydney, where he was appointed secretary to the Australian Museum and assistant to the curator, Dr. Pittard. On the death of his chief in 1861 Krefft became curator, and employed his spare time in publishing valuable monographs on various Australian animals. In 1874 he resigned on account of differences with the trustees, retired into private life, and died on 18 February 1880.

His principal works are *Snakes of Australia* (1865-9), *Australian Vertebrata* (1865-73), and *Mammals of Australia* (1871), all published in Sydney. He was the first to describe scientifically *Ceratodus* (q.v.), which had been discovered in Queensland by William Forster and submitted to Krefft for examination; and his demonstration of its connection with certain fossil forms was acknowledged as decisive and valuable by Agassiz. His work in connection with extinct giant marsupials was used and praised by Sir R. Owen.

Kunzea, a genus of the family Myrtaceae, limited to Australia, consisting of heath-like shrubs. The flowers are white, lilac-purple, or yellow; calyx-tube globular, with 5 lobes, green or scarious at the edges; petals 5, orbicular; stamens free, in one to several series; capsule not woody. *K. corifolia* (Tick-bush), a spreading floriferous shrub, is reputed to be frequented by ticks. *K. Muelleri*, a low spreading undershrub with bright yellow flowers, is an alpine species. The wood of *K. peduncularis* was used by the aborigines for making waddies or clubs.

Kurnell. See EXPLORATION BY SEA.

Kurrajong, aboriginal name of several trees belonging to the orders Sterculiaceae and Malvaceae, and occasionally to other trees with a tough bark, but of late years confined to the Black Kurrajong (*Brachychiton populneum*, syn.

Black Kurrajong.

Sterculia diversifolia), an umbrageous tree that ranges from Gippsland to the Gulf of Carpentaria, with a preference for limestone country.

It attains a height of 60 feet. The flowers occur in sprays; calyx bell-shaped, yellowish without, reddish within; petals obsolete; fruit a follicle 1½ to 2 inches long, thick and leathery; leaves on long stalks, shining, very variable in form, some being entire and shaped like a poplar leaf, others more or less deeply 3-lobed (rarely 5-lobed). A white gum is exuded.

The kurrajong is the best Australian fodder-tree; cattle and sheep devour the leaves eagerly, and in dry seasons have been known to exist for long periods with hardly any other food. Branches within the reach of grazing animals are always cropped. In New South Wales the trees are exempt from timber licences, and may not be cut down, though they may be lopped. Pastoralists are beginning to make small kurrajong plantations, as the trees grow readily from seed, taking six or seven years to become established. A strong fibre made from the bark is used by the aborigines to make fishing-nets and dilly-bags; they also eat the young roots, which when boiled have a flavour like that of turnips, but sweeter. The kurrajong is an ornamental tree, suitable for parks and gardens.

Other trees to which the name 'kurrajong' has been applied in the past are *Commersonia echinata* (Brown K.), *Brachychiton Gregorii* (Brown K.), both of the Sterculiaceae; *Hibiscus heterophyllus* (Green K.), *Plagianthus sidoides* (Tasmanian K.), both of the Malvaceae. It has also been occasionally applied to a *Trema* (Urticaceae) and to a *Pimelea* (Thymelaceae). The spelling varies greatly, currajong, currijong, and koorajong being the variants most frequently met with.

Kurrajong, the name of a hill district overlooking the Hawkesbury valley near Richmond in New South Wales, named from the profusion of kurrajong trees with which it was originally covered and which still clothe its upper slopes. It is now known as a health resort and a good situation for citrus orchards.

L

Labiatae. a large family of plants of world-wide distribution, including the well-known culinary herbs mint, thyme, and sage. Twenty genera with 148 species are indigenous to Australia; only five genera are endemic. *Anisomeles salvifolia* is said to yield a delicate perfume; *Coleus* is a tropical genus, but is represented in Australia by *C. scutellarioides;* of *Dysophylla,* whose leaves often have a fetid odour, the Australian species is *D. verticillata. Prunella, a small* genus, is represented by *P. vulgaris,* the common 'self-heal' of Europe. The indigenous *Salvia plebeia* extends to eastern Asia. *Westringia rosmariniformis* (Coast Rosemary) is a useful protective shrub, suitable for exposed positions on the sea-coast. See MENTHA, OCIMUM, PROSTANTHERA.

Labillière, FRANCIS PETER (1840-1895), born on 13 August 1840 at Melbourne, in 1859 went to England with his father, entered the Middle Temple, and was called to the bar on 6 June 1863. From 1869 onwards he advocated imperial federation, and in 1884 was made secretary of the Imperial Federation League. In 1874 he urged the colonial office to annex eastern New Guinea. In 1878-9 he published in London a two-volume *Early History of the Colony of Victoria* which at the time added a good deal to historical knowledge. He died in England in 1895.

Labour Parties. As early as 1842 there are traces of a tendency among artisans and manufacturers' employees to become politically active as a class; but the associations which they formed or joined, such as the Mutual Protection Association of Sydney (1844), included small tradesmen and farmers, and so were not avowedly 'labour' organizations. The gold discoveries, which allowed every man to gamble for wealth and enriched many who had formerly been employees, for a time allayed industrial discontent; but from the mid-sixties onwards the formation of trade unions (q.v.) proceeded with some vigour, and in 1872 the miners of Bendigo in Victoria formed an association which grew into the Amalgamated Miners' Association of Victoria, the first industrial body to exercise any important political influence. Isolated attempts were soon made by local groups to return 'labour' representatives to the colonial parliaments; and in 1884 an intercolonial trade-union congress, held in Melbourne, urged organizations in the various colonies to elect a parliamentary committee, and where possible to obtain for labour direct representation in parliament. The formation of the Australian Socialist League in Sydney in 1887, the writings of William Lane (q.v.), and the visit of Henry George, stirred up political enthusiasm, and at the Hobart conference of 1889—when the Australian Federation of Labour was formed—it was resolved not to support candidates who did not adhere to the labour platform. Acts providing for the payment of members, which were passed in all the colonies by 1890, made it possible for a working-man to devote all his time to parliamentary work. Then followed the maritime strike of 1890 (see STRIKES) in which all the important unions became involved; its failure convinced unionists of the difficulty of securing reforms by direct industrial action when the government was hostile. Action was therefore taken to form a political labour party in all the colonies except Tasmania. In *New South Wales* the trade unions of Balmain had sent Jacob Garrard to parliament in 1880, undertaking to pay him a salary; the experiment was not a success, and he attached himself to one of the existing parties. In 1883 Angus Cameron was elected by West Sydney to represent labour; Frank Cotton stood in the same interest for East Sydney in 1890, but was defeated. After the failure of the 1890 strike a constitution for the proposed party, and a platform for submission to the electors of New South Wales, were drafted and approved by a labour conference; labour electoral leagues were rapidly and widely organized, and in June 1891 45 candidates faced the general election, 36 being returned. Of these 16 were elected by city and suburban constituencies, 4 by coal-miners, and 16 by agricultural and pastoral constituencies. Among the new members were J. S. T. McGowen and Joseph Cook, both of whom in later years held high office. This remarkable success at the polls was partly due to the stirring speeches made by Sir George Grey (q.v.).

If it could retain its 'solidarity,' the party held the balance of power in a house of 141; but its first pledge—'to vote in the House as a majority of the Party, sitting in caucus, has determined'—proved unworkable, and schisms occurred whenever the fiscal question (at that time the chief matter in dispute between the other political parties) was raised. General support was, however, given to Parkes, who had placed on his programme seven labour measures, including bills for electoral reform, the extension of local government, and the improvement of conditions in coal-mines, workshops and factories. When, however, Parkes refused to accept their proposals for the shortening of coal-miners' working hours, the labour members abandoned him, and George Dibbs, becoming premier, introduced a protectionist tariff and split the party hopelessly. At the elections of 1894 two sections—one pledged, the other independent—sought the labour vote, and 27 members (15 of whom were pledged) were returned to a parliament of 125; among them were J. C. Watson (q.v.) and W. M. Hughes (q.v.). After some negotiations the sections united, on the basis of the following pledge, which remained practically unchanged for twenty years:—

> I hereby pledge myself not to oppose the selected candidate of this or any other Branch of the Political Labour League. I also pledge myself, if returned to Parliament, on all occasions to do my utmost to secure the carrying out of the principles embodied in the Labour Platform, and on all questions, and especially on questions affecting the fate of a Government, to vote as a majority of the Labour Party may decide at a duly constituted caucus meeting.

At the elections of 1895 19 labour members were returned, and held the balance of power; George Reid, then premier, took care to adapt his policy as much as possible to their predilections, carrying out public works by day labour, and passing land and income taxes, a franchise extension act that gave the suffrage to the police, a workshops and factories act, and a coal-mines regulation act.

The elections of 1898 strengthened the labour position, since Reid's followers were much reduced in number. In September 1899 the party —which had long since adopted the policy of supporting on non-labour policies the party that would concede most to labour's policy—ejected Reid and transferred its support to W. J. Lyne, who during his term of office (1899-1901) passed an early-closing act, an old age pensions act, a miners' accident relief act, and much similar legislation.

From 1901 onwards the federal parliament became the main scene of labour's advance, and Watson and Hughes, besides minor leaders, transferred their activities to that sphere. In New South Wales the party continually increased its strength, numbering in 1901 24 out of 125, in 1904 25 out of 90, in 1907 32 out of 90, and in 1910 becoming an absolute majority (46) of the legislature and attaining office under J. S. T. McGowen. The acceptance of woman suffrage and the development of the State arbitration system (for which see INDUSTRIAL LEGISLATION) were admittedly due to labour support. The party's greatest handicap was its lack of representatives in the legislative council, which is nominee; but Reid in 1899 nominated four labour councillors and Lyne in 1900 added two more.

In *Queensland* the first attempt to secure direct representation of labour was made in 1886, when W. M. Galloway stood at a by-election for Fortitude Valley and secured only 111 votes. At the elections of 1888 four labour candidates ran, but secured only 1261 votes between them; T. Glassey, however, who had been elected as a supporter of the Griffith ministry, left that party and declared himself a labour member, and was joined by J. P. Hoolan. In 1892 T. J. Ryan and G. J. Hall were elected on the labour platform, and these four formed the first distinct labour party in the house, Glassey acting as leader. The elections of May 1893 returned 16 labour members, among them Anderson Dawson, Andrew Fisher and Charles McDonald; and in March 1896 20 were returned out of a total of 72. In June 1898 the labour convention adopted a new platform. Candidates pledged themselves to support the principles contained in the platform, and, in the event of their not being selected, not to oppose the candidature of the duly selected nominee. The elections of March 1899 returned 23 labour members, and two bye-elections later in the year raised the party's strength to 25. When in November the Dickson ministry resigned, Anderson Dawson (q.v.) formed the first labour ministry known to the world. Dawson was premier and chief secretary, C. B. Fitzgerald attorney-general, Henry Turley home secretary, W. Kidston treasurer and postmaster-general, W. H. Browne minister for mines and public instruction, H. F. Hardacre minister for lands and agriculture, and Andrew Fisher minister for railways and public works. Being from the start in a hopeless minority, this ministry lasted only seven days.

After federation the Queensland legislature, like those of the other States, lost several of its best men to the Commonwealth parliament. When in September 1903 the Philp ministry resigned, a coalition was made between labour and the regular opposition, and Arthur Morgan, resigning the speakership, formed a ministry with W. H. Browne as minister for mines and W. Kidston as treasurer. At the elections of 1904 35 labour members were returned. In January 1906 Morgan resigned and Kidston became premier, but soon left the party; the coalition then disappeared, labour regained its independence, and Kidston found himself in a position similar to that of Reid in New South Wales in 1895-9. The elections of 1907 returned 18 labour members, who, as Kidston's followers were in a minority, held the balance of power; those of 1908 gave labour 23 representatives, who for the time supported Kidston, but at the elections of 1909 stood alone and increased their number by four. Kidston and Philp had meanwhile coalesced, and the labour party was now the official opposition. In 1912 it lost two seats, but in 1915 came into power with an overwhelming majority under T. J. Ryan (not the shearer of 1892), and entered on a career of 'advanced' legislation and administration that is still (1925) uninterrupted. This long tenure of power is partly accounted for by the abolition of the legislative council in 1922, and by the system of proxy voting in the single chamber that remains, whereby the leader of a party can vote the full strength of his party whether present in parliament or not.

The first labour member for *Victoria*, Charles Jardine Don, was elected for Collingwood in August 1859, worked as a stonemason all day, and attended parliament at night; in 1861 he lost the seat to Graham Berry by 46 votes only. In 1859 the diggers of Ballarat paid the expenses of Duncan Gillies, who afterwards voted as a conservative. In 1880 the general secretary of the Amalgamated Miners' Association was an unsuccessful candidate for Clunes and Creswick. In 1891 John Hancock, a leading trades-hall unionist, was elected for Collingwood by a big majority; this victory resulted in the creation of a labour political organization affecting the whole colony, known as the 'Progressive Political League.' The parliament of 1889 already contained two men who could be classed as pro-labour, W. Maloney and W. A. Trenwith; W. D. Beazley joined the movement, thus giving labour in 1891 a strength of four.

After the elections of 1892 it had 10 in a house of 90. William Shiels (q.v.), then premier, who advocated most of the Progressive League's measures, failed to carry them, and was displaced by J. B. Patterson; the financial crisis of 1893 discredited him, and in the elections of 1894 labour secured 16 seats. The Victorian labour party, however, has never prospered like those of other States; its high-water mark was reached in 1908 with 21 members out of 65. This comparative unsuccess is probably connected with the fact that nearly all Victorian labour members have been elected by metropolitan constituencies, the country districts holding aloof, so that the party has not been able to understand the requirements of the State as a whole. In 1908, for instance, 12 of the 21 members were metropolitan and five more represented goldfields; this proportion may be usefully compared with that of the New South Wales members in 1891. For some such reason the labour party has wielded less than its due

influence in Victorian politics, and has never held the balance of power, since the other parties have always been willing to combine against it.

In *South Australia* the first sign of labour interest in politics was the formation in January 1884 of the United Trades and Labour Council, which in 1887 secured the return of seven members and in 1890 of 14. None of these, however, could be classed as labour representatives —the only member so describable was G. M. Cotton, who was returned in 1888 to the legislative council. After the maritime strike of 1890 labour became more active. In January 1891 a meeting of executives of the unions and workers' clubs resolved to put forward direct representatives of labour. A platform was drawn up, a pledge adopted, and a subscription raised among the affiliated societies to pay expenses; three members were chosen to run for the legislative council, and all three were elected in the following May. This success encouraged the council in July to call for nominations of 15 candidates; voting for the 15 took place in the following February, and T. Price (q.v.), who came 16th on the list, was allowed to be included. At the 1892 elections eight of these candidates were elected, including E. L. Batchelor, W. O. Archibald and T. Price; these formed the first 'United Labour Party.' At the elections of 1896 11 labour members were returned, and by 1898 the party had also four members in the legislative council. Its isolation was not so complete as in other colonies, and in the Holder ministry of 1899-1901 Batchelor was minister of education and agriculture. Both Holder and Batchelor resigned in 1901 to enter the federal parliament, and for a few years labour in the State was under a cloud; but in 1905 the tide turned, 15 labour members were returned, and coalesced with the 'liberals' under A. H. Peake. On 26 May a coalition ministry was formed, with T. Price as premier. Government bills being rejected by the legislative council in 1905 and 1906, Price went to the country, and the labour party returned with 19 members; in 1908 the number was raised to 20, in a house of 42. Price taking the agent-generalship, A. H. Peake (the 'liberal' leader) succeeded him, and in 1909 broke up the coalition and joined his former antagonist Richard Butler; but at the next elections (1910) labour won 22 seats, Peake resigned, and a wholly labour ministry was formed under John Verran. In February 1912 the Verran ministry was defeated, and the number of labour members fell to 16; the Peake-Butler coalition returned to power, and labour went into opposition for 12 years.

In *Western Australia*, where self-government was established in 1890, the discovery of gold brought a rush of miners from the eastern colonies. A Trades and Labour Council was formed in Fremantle on 9 December 1892, and a platform adopted, including electoral reform, manhood suffrage, and an eight-hour day. In May 1897 C. H. Oldham was elected as a labour representative, although members were not yet paid. Early in 1899 Hugh de Largie, president of the Australian Workers' Association, suggested the summoning of a trade union and labour congress; the meeting was held in Coolgardie in April, political action was decided upon, and a fighting platform adopted, including payment of members, redistribution of seats on a proportional basis, and compulsory conciliation and arbitration on New Zealand lines. Federation was also approved of. At the State elections of 1901 a party of six was returned, which in 1904 with a more liberal franchise grew to 21 out of a total of 50 members. Five independent members joined labour in expelling the James ministry, and a labour ministry was formed under Henry Daglish. He resigned, however, in August 1905, and the labour party lost ground at the elections. Twenty-two members were returned at the elections on 11 September 1908, but one member was unseated on appeal and lost at the fresh election. In 1908, however, the party came back 22 strong, and in October 1911 gained a complete victory, defeating the government that had been in power for six years and obtaining 34 votes to the opposition's 16. John Scaddan at once formed a purely labour ministry (that of Daglish had included independent members) and held office until August 1915.

In *Tasmania* labour made its first move in 1893, and in the following year Allen McDonald was returned for Launceston. Leagues with attractive names were formed in Hobart and Launceston, but by July 1896 were all absorbed into the 'Democratic League of Tasmania.' No political successes, however, were obtained until the elections of 1903, when three labour members were returned out of a total of 35. At the elections of 1906 this number was increased to seven. The parliament of 1906-9 altered the constitution, reducing the numbers of the legislative council to 18 and of the assembly to 30, and in the 1909 elections labour secured 12 seats out of the 30. The Lewis ministry being defeated on a vote of censure, John Earle formed the first labour ministry, but could not attract sufficient outside support to give him a majority, and Lewis came back to office. The elections of 1912 sent 14 labour members to parliament.

Labour in Federal Politics.—Since the inauguration of the Commonwealth labour members have played an important part in federal politics, mainly because the party for 15 years chose its best men to represent it there. In the first parliament there were eight labour senators out of a total of 36, and 16 representatives out of 75; these included W. G. Higgs from Queensland, G. F. Pearce from Western Australia and G. McGregor from South Australia among the senators, and among the representatives J. C. Watson, W. M. Hughes, W. G. Spence (all from New South Wales), Andrew Fisher, C. McDonald and J. Page (Queensland) and E. L. Batchelor from South Australia. J. C. Watson was chosen leader.

At the elections of December 1903, 14 labour senators and 25 representatives were returned; and, when the Deakin ministry resigned in April 1904, J. C. Watson formed the first Commonwealth labour ministry, as follows:—prime minister and treasurer, J. C. Watson; attorney-general, H. B. Higgins; minister for trade and customs, A. Fisher; minister for external affairs, W. M. Hughes; postmaster-general, H. MacMahon; minister for defence, A. Dawson; minister for home affairs, E. L. Batchelor; vice-president of the executive council, G. McGregor. H. B. Higgins was not actually a labour member, but was in sympathy with the ministry's policy. This ministry was defeated in August by a coalition of the parties led by Deakin and Reid: but, when in the following June this coalition went to pieces, the labour party supported Deakin wholeheartedly for two years. In December 1906, 27 labour members were returned to the house of representatives and 15

to the senate. In 1907 the party lost its leader, J. C. Watson; his place was taken by Andrew Fisher, who in November 1908 formally withdrew the party's support from Deakin, and on the 17th formed a ministry of his own, with the qualified support of the Deakin party. In May 1909 Deakin in his turn withdrew this support, coalesced with the former opposition led by Joseph Cook, and formed a new administration that saw the parliament out.

In April 1910, however, labour secured an unmistakable victory, sending 42 members to the house of representatives and winning all the 18 vacant seats in the senate. On 29 April Andrew Fisher formed his second ministry, the first labour ministry with a substantial majority behind it; and the legislation of 1910-13 embodied many of the party's most cherished ideals, including land taxation, the establishment of a Commonwealth Bank, the enlargement of the old age pensions scheme and of the scope of federal arbitration, and acts providing for workmen's compensation and a maternity allowance.

Lacewings. See PLANIPENNIA.

Lachnostachys, a genus of the family Verbenaceae, endemic in Western Australia. The calyx is broadly bell-shaped, with 5 to 8 lobes, densely woolly; corolla shorter than the calyx, truncate or shortly and equally 5-8-lobed; stamens 5-8, protruding, inserted on the margin of the corolla or between its lobes; fruit hard, usually one-seeded and enclosed in the calyx; leaves opposite, undivided. In several species the flowers are concealed in a dense cottony woolly mass, which has given rise to the name 'blanket-plants.'

Ladybirds. Great interest attaches to the Australian members of this group, as efforts, in some cases successful, have been made to introduce many of them to other parts of the world, in order to check certain destructive insects. With few exceptions the species feed on scale-insects, aphides, and other small homopterous insects, some of which are very troublesome to fruit-growers. One of the most useful species is *Leis conformis* (bright yellow, with numerous round black spots); a colony of these ladybirds appearing on a rose or other bush affected by aphides will in a few days completely free it. Orange, apple, and other fruit-trees—especially the peach—benefit from their work. All attempts to acclimatize them in California, South Africa, England, and India have failed, though in several instances many thousands of specimens have been landed alive in those countries. The typical form does not occur naturally in Western Australia, its place there being taken by a smaller species, *Cheilomenes quadriplagiata*. Another yellow-and-black species, *Coccinella transversalis*, occurs in Australia (all States), the Malay Archipelago, etc.; it feeds on similar insects, but its larvae are attacked by so many kinds of parasites that the species seldom gets a chance to multiply as abundantly as is desirable. The beautiful blue-and-yellow ladybirds of the genus *Orcus* feed almost solely upon scale-insects; in New South Wales and Queensland several species occur in abundance upon orange-trees attacked by the red and white scales. A small species, *O. chalybeus*, is perhaps the most useful; but, despite repeated attempts to multiply it in California, it appears barely able to maintain itself there, nor does it appear able to live in the comparatively dry orange-growing districts of South and Western Australia. *O. lafertei* and *O. coelestis* are useful in tropical Australia; *O. australasiae* is the most widely distributed species, but is seldom found in orchards.

The most noted Australian ladybird is a small red-and-black one, *Novius cardinalis*, that feeds almost solely upon the cottony-cushion scale-insect (*Icerya purchasi*); although widely distributed in Australia, it was almost unknown till its introduction to the United States, where in a brief period it almost entirely freed the orange-groves of California from that scale, which previously had threatened their destruction. It has also been successfully introduced into South Africa, Egypt, Spain, and Italy. The success obtained with this species was so pronounced as to rouse hopes that most of the destructive insects of the world could be controlled by introducing other insects to feed upon them; as the estimated damages due to insects have been put down at one-tenth of all the crops produced, the saving in this way would amount to many millions of pounds annually. Hundreds of species of ladybirds and other insects have since been introduced to various countries, but very few of these have proved of much use, as climatic conditions, parasites and (in some cases) birds have prevented them from increasing to useful proportions. Parasites useful against the codling moth have also been persistently sought, with, as yet, very little permanent benefit.

A small black-and-yellow hairy species, *Cryptolaemus montrouzieri*, which feeds largely upon mealy-bugs, has been successfully introduced into Hawaii and California; a few specimens placed in a glass-house for plants will soon free it from mealy-bugs. A small black hairy species with red abdomen, *Rhizobius ventralis*, feeds upon many kinds of scale-insects. After its introduction to the United States it multiplied greatly, and proved to be of much use for some years, but is now regarded as of secondary importance; largely owing to this species, and to others of its genus, the San Jose scale (*Aspidiotus perniciosus*) did not become as troublesome in Australia as at one time it threatened to be. The small hairy species of *Scymnus*, abundant everywhere in Australia, feed largely on scale-insects; but a very small species, *Scymnus vagans*, feeds upon red spider (*Tetranychus telarius*), red mite (*Bryobia pratensis*) and other minute pests. *Scymnus notescens*, one of the few species with distinctive elytral markings, feeds on aphides, and may be seen in abundance on cucurbitaceous plants affected by such insects. The species of the sub-family Epilachnidea are all plant-feeders; but only one, *Epilachna 28-punctata*, is a serious pest in Australia—it extends over the eastern and northern parts and is destructive to the potato, tomato, and other solanaceous plants, as well as to the pumpkin and its allies. Unfortunately it very closely resembles one of our most useful species, *Leis conformis*, and the latter in consequence often suffers at the hands of growers, who ignorantly destroy one of their best friends. A second species, *E. guttatopustulata*, attacks similar plants, but is much less abundant.

A. M. L.

Lalor, PETER (1827-1889), born at Tinakill in Queen's County, Ireland, on 5 February 1827, and educated at Trinity College, Dublin, adopted the profession of civil engineer and in 1852 sailed for the goldfields of Victoria, where he first sampled the Ovens diggings and then worked a claim at Ballarat on the Eureka lead.

Just as this claim was developing riches, the unrest among the miners in October-December 1854, always associated with the Eureka Stockade (q.v.), drew Lalor away from work and absorbed him in the business of the Ballarat Reform League. On 30 November he was chosen leader of the rebels, and did his best to organize a fighting force; but when on 3 December the stockade was stormed he was wounded in the shoulder and carried to safety by a few friends. Proclaimed an outlaw, he remained hidden in Geelong until the trials of other rebels proved abortive; then he returned to Ballarat, and in November 1855 was elected to the legislative council by his digger friends. The next year he was chosen by South Grant—a constituency that included Ballarat West—to represent it in the new legislative assembly, and held the seat until 1871, being chairman of committees from 1859 to 1868. From 1868 to 1874 he devoted most of his time to developing Clunes. In 1871 he lost his seat, but regained it in 1875, and joined Graham Berry's first ministry as commissioner of trade and customs (August-October 1875), holding the same office in Berry's second ministry (1877-80); in this he was also postmaster-general for about six weeks (May-July 1877). On 22 July 1880, mainly as a challenge to Berry's enemy, James Service, Lalor was elected speaker; in this position he behaved with unexpected firmness and impartiality for seven years, but severe illness forced him to resign on 29 September 1887. Parliament granted him £4000 for past services, but he did not live long to enjoy it, dying at Melbourne on 9 February 1889.

Lambert, GEORGE WASHINGTON, born at St. Petersburg in September 1873 and for a short time educated privately in England, was brought by his grand-parents to Sydney in 1883 and, after a short but vitally important visit to the Nevertire district of New South Wales (where he saw and was absorbed by the Australian bush), worked for four years as a clerk in Sydney. A second visit to the bush (during which he worked as a station hand), and the encouragement of B. E. Minns, prompted him to join the art school of Julian Ashton (q.v.), where he soon distinguished himself by selling pictures to the Sydney art gallery. In 1899 he became notable as the painter of 'Across the Blacksoil Plains,' still one of the best-known and most generally admired Australian paintings, which is hung in the Sydney gallery. Winning a scholarship offered by the Society of Artists (see ART) which provided funds for three years' study in Europe, he left Sydney in 1900, studied for a time at Colarossi's studio in Paris, and then settled down in London to do black-and-white work for the *Strand* and *Pall Mall* and to make a serious study of portrait-painting. In 1903, and in each year from 1905 to 1911, portraits or groups of his were hung (usually on the line) at the Royal Academy and by 1911 he was among the few recognized portraitists of the first class: he was a foundation member of the Modern Society of Portrait Painters, a member of the International Society of Sculptors, Painters and Gravers, and an associate of the New Salon in Paris. Among his portraits of this period are those of Sir George Reid (in the federal parliament-house at Melbourne), the Gaekwar of Baroda, Lady Beaverbrook and Cunninghame Graham. His reputation now spread beyond London and Paris, and 'The Mask,' his Academy picture in 1911, was exhibited in Venice and bought there for a gallery in St. Petersburg. During the war he served as works officer of the British timber supplies department (1915-7) and official artist with the Australian light horse in Palestine (1917-8): in 1919, being commissioned by the Australian war museum to paint records of the landing on Gallipoli, the light horse charge at the Neck, the Beersheba charge, and other great deeds of the war, he accompanied the official war correspondent in a tour of Gallipoli and Palestine to acquire a thorough knowledge of the scenes he had to depict, and in 1921 came back to Australia to complete his pictures among the men they concerned. In 1922 he was elected an associate of the Royal Academy.

See *The Art of George W. Lambert, A.R.A.* (Sydney, 1924), which includes a careful study of his methods and aims as a painter. W.M.

Lambertia, a genus of the family Proteaceae, endemic in Australia, consisting of shrubs with leaves usually in whorls of 3. The flowers are red or yellow, 7 together within a circle of imbricate, coloured bracts; corolla regular, the tube elongated, surmounted by narrow, spirally revolute lobes; anthers inserted on the lobes and revolute with them; fruit a short, hard, truncate follicle with 2 valves, the lower margin of each valve produced into a thick horn; seeds flat, bordered by a narrow margin. Most of the species are confined to Western Australia; the only eastern representative is the Honey Flower (*L. formosa*)

Honey Flower.

which has acquired its popular name from the large quantity of honey in the flowers. It is confined to the coastal sandstones of New South Wales, extending as far south as Braidwood.

Lamington, BARON. Charles Wallace Alexander Napier Ross Cochrane-Baillie, 2nd baron Lamington, born on 29 July 1860 and educated at Eton and Christ Church, Oxford (B.A., 1881), was in 1885-6 assistant private-secretary to Lord Salisbury (then prime minis-

ter) and represented North St. Pancras in the house of commons from 1886 to 1890. Succeeding his father in that year, he travelled through Siam and Tonquin for nearly two years, and on 9 October 1895 was appointed governor of Queensland, assuming office on 9 April 1896. During his term of office he travelled a great deal in Queensland and New Guinea. He left office on 19 December 1901, returned to England, and from 1903 to 1907 was governor of Bombay. (G.C.M.G., 1900; G.C.I.E., 1903.)

Land Legislation, Tenure, and Taxation. The development of land legislation in Australia has been influenced by the character of the early settlement, steadily widening knowledge of the extent and resources of the continent, growth of the population, improvements in internal and overseas transit facilities, the development of agricultural science, and the consequent increase in the number of uses to which the soil might be put. Along with these purely economic factors others of a political character have played a part, especially (*a*) the rise of a Labour party, hostile to the further alienation of land, and to the existence of the large landowner; (*b*) the influence of prolonged and intensive propaganda by followers of Henry George; and (*c*) the general acceptance of the doctrine that the best line of social progress results in the close settlement of rural areas by a nation of industrious and sturdy yeomen.

A detailed survey of the extremely complicated history of land legislation and administration in each State is here impossible. Most legislation has been of an experimental nature, and later experience has soon made amendments necessary; almost every session of every colonial or State parliament has witnessed the passage of new land laws, and the position has consequently become at times very confused, in spite of attempts at simplification and consolidation. Still, the general trend of theory and practice can be stated in broad outline under four periods.

Period of free grants (1788-1831).—The early governors had power to make grants of land to suitable persons, whether free settlers or emancipists. At first only small blocks were alienated; but with the advent of the pastoral industry, the abandonment of all attempts to confine settlement to the Sydney area, and the realization of the vast expanse available for settlement, large holdings were permitted. Officers and officials helped themselves to big blocks; the British government granted 1,000,000 acres to the Australian Agricultural Company, 350,000 to the Van Diemen's Land Company, and 250,000 to the promoters of the Swan River settlement in 1829. By 1831 probably 4,000,000 acres had been given away; much of it was in large or very large holdings, and in most instances the prescribed small quit-rent was not being paid.

Period of land-sales and pastoral leases (1831-1851).—In 1825 the sale of land began. At first private tenders were called for, the minimum being fixed at 5s. per acre, and lands in eastern New South Wales were valued by a commission to fix prices for future sales. In 1831 free grants were abolished, and sale by auction was introduced. The upset price, 5s. an acre, was raised to 12s. in 1839, and to £1 in 1842. An imperial act of 1842 decreed that half the proceeds of land-sales was to be spent in assisting immigration. British policy at this time was largely influenced by the ideas of Edward Gibbon Wakefield (q.v.), who was urging that land be sold at a 'sufficient price,' and the revenue thus raised be devoted to public works and the immigration of agricultural labourers. The price would be so high that it would be impossible for the assisted immigrants to desert their jobs and buy land until they had worked some years in the colony, so that settlement, public works, and labour supply would progress *pari passu*. South Australia was founded on lines inspired by Wakefield; but for various reasons, of which one of the chief was a wave of land speculation, the original scheme failed and had to be discarded. When self-government came, most of the colonies regarded land-sales receipts as general revenue, and used only a small and fluctuating part for immigration; the rest went to defray general expenditure.

Usually land was not sold until it had been surveyed, but the growth of the sheep industry made necessary the framing of a policy for dealing with large outback areas, unsettled and unsurveyed, on which flocks of sheep were (technically) trespassing. Until 1846 the owners of such flocks, known as 'squatters,' had to obtain annual licences, and efforts were made to forbid unlicensed grazing; but the position was unsatisfactory to all parties—the licensee, having no fixed boundaries and no security of tenure, would not erect decent buildings or fences, and the authorities had the thankless task of trying to police the pastoral areas. In 1847, after a ten years' struggle, the pastoralists secured from the British government orders in council that established a new system of tenure. Land was to be divided into three districts—settled, intermediate, and unsettled. In the settled district pastoral leases for one year were allowed; in the intermediate area the tenure was extended to eight years, and in the unsettled lands to 14 years. During the currency of the lease (except in the intermediate area) the holder could not be disturbed by any buyer; he could purchase any portion of his holding at any time at £1 an acre, and on the expiration of his lease had a pre-emptive right to all or any part of his land. For the intermediate area a unique form of lease was devised; although the nominal term of it might be anything up to eight years, yet at the end of any year it might be cancelled on 60 days' notice and the land sold over the lessee's head.

These orders, by giving the pastoralist security of tenure and the first right to buy any part of his holding, were a great boon to the wool industry. Lessees at once began to make improvements on their stations and increase the efficiency of their work. But, while security of tenure was justifiable, the pre-emptive right roused much hostility from governors and the public; for the lessee not merely bought up the 'eyes' of his holding, and thus rendered the rest of it useless to anyone but himself, but also secured this freehold at £1 an acre, which was often far below the price it would have brought if sold by auction. So keen was the opposition to these concessions, especially in Victoria, that the governor of that colony virtually refused to put the orders into force. In New South Wales, however, the governor acted upon them, and the lessees benefited considerably thereby.

Period of selection before survey (1861-1890).—After 1850 the whole character of the land problem changed. Self-government was granted to all the colonies except Western Australia, and land tenure became a matter of local legislation. The gold-rush brought a large addition to the population, and when the rush subsided many ex-diggers and other immigrants wished to

settle on the land. Some had found fortunes on the goldfields; but it is probable that most of them had only a small capital, would be unable to pay cash in full for farms, and required small holdings, suitable for agriculture. To help such men to find land, and thus build up a race of 'sturdy yeomen' side by side with the pastoralists, was therefore the guiding principle of land legislation from 1860 onwards.

The outstanding effort to foster the settlement of small farmers in New South Wales was Robertson's scheme for 'free selection before survey' (1861). It contained two important new points: (*a*) pastoral leases were granted for one year if within the 'settled' districts, or five years if outside, but the whole leasehold area, surveyed or not, was open to selection and sale at any time; (*b*) selectors could pick a limited area (40 to 320 acres) in any place, at £1 an acre, and pay as deposit one quarter of the purchase-price—they must then reside on the land for three years, make improvements worth £1 an acre, and pay off the balance of the purchase money virtually at will, with 5 per cent interest.

This plan—'conditional' purchase by residence, by improvements, and instalments—was destined to play a large part in the subsequent history of land-settlement. The underlying principle was copied by almost every colony sooner or later, e.g. in Duffy's legislation in Victoria (1862), and in Strangways's act of 1869, which introduced purchase by instalments to South Australia. Much was expected of it; and it has established some small farmers on the land, especially since 1890, when it was developed and surrounded with safeguards against abuse. But its chief and first effect was to precipitate a fierce struggle between the squatter and the invading selector, especially in New South Wales. Some selectors really wished to take up land for farming; others were little better than rogues. The latter picked a selection on a sheep-run, not in order to cultivate it, but in order to compel the harassed leaseholder to buy them out at a high price. Whether the selector was a settler or a speculator, he was unwelcome to the squatter, who therefore set to work to defend his run from invasion by buying up the 'eyes,' and as much besides as he could afford. He sought the aid of the banks in buying land, and employed 'dummies' to take up selections on his behalf; he even sometimes went so far as to obtain paupers from the asylums and put them on allotments. He bought heavily at auction sales when any part of his holding was put up for sale, and, as he could usually pay cash or offer to buy large tracts, he beat the smaller men in the auction room. In short, by adopting as a defence offensive methods that were 'sometimes ingenious and sometimes dependent for success on barefaced perjury' (Coghlan), the big leaseholders emerged from the struggle big freeholders. The legislation that had been intended to settle eastern Australia with industrious yeomen handed a great area of it over to big landowners. In New South. Wales, between 1861 and 1884, more than 39,000,000 acres were disposed of in one way or another—over half of the area by conditional purchase; yet this vast alienation gave the colony only 21,000 more settlers, and only 420,000 acres more were under the plough in 1884 than in 1861. In Victoria similar developments took place during the same period, while in South Australia in 1891 539 persons held two-fifths of the alienated area in estates of over 5000 acres. Much of the land in the big holdings was inside the area suitable for agriculture, and was well supplied with roads and rail-facilities; only 50 miles from Adelaide, for instance, there was an estate of 70,000 acres freehold, with good rich soil and a 20-inch rainfall. Similar cases could be quoted in all the colonies.

Period of experiment and reform (1890 onwards).—By the later eighties it was generally recognized that the whole land problem must be reconsidered. Thanks to irrigation and improvements in refrigerative processes, new avenues of production were being opened up. Refrigeration alone meant that Australia could develop an export trade in perishable commodities, such as meat, butter, and fruit; hence grazing, dairy work, and orcharding entered upon a new phase of growth, bidding for a world-market. Meanwhile the use of superphosphates and of dry-farming methods was turning into possible wheat-fields large belts of the low rainfall area, especially in the mallee country of Victoria and South Australia. Henry George's visit stimulated a widespread discussion of land problems, and the Labour party was soon to make its influence felt. Public men were realizing that Australia must carry a much larger population to defend the continent as well as to develop it; but immigrants could not be welcomed unless there was suitable land on which to settle them.

Since the later eighties, therefore, and especially since Australia's recovery from the depression of the early nineties, new or amended land-laws have been devised, having as their object (1) the settlement of a rural population on holdings which, if properly used, are not too large to be fully worked or too small to provide a comfortable family living; (2) the utilization of the soil to the best purpose for which it is fitted; (3) the breaking-up of large pastoral estates suitable for closer settlement and cultivation; (4) the assistance of rural producers, especially small holders, by the provision of water supply, credit facilities, produce depots, etc. All this intensified activity has made necessary the provision of adequate administrative machinery, and in each State a lands department controls all matters relating to crown lands; it is often assisted by decentralized local land boards, and special bodies to deal with such matters as irrigation, closer settlement, or advances to settlers. The departments are faced by two outstanding problems. On the one hand further alienations of land must be watched to prevent a repetition of the blunders made in the past. How big this task is will be realized from the table given on next page.

Thus, during less than 20 years State departments have leased or sold an area equal to about three-eighths of the total area dealt with during the whole of the nineteenth century; in two decades, indeed, they have alienated or put into process of alienation about half as much land as in the whole previous period of settlement. On the other hand governments have endeavoured to undo the past (*a*) by repurchasing big estates for subdivision into small farms, (*b*) by taxing the big owner in order to drive him into better use of his land, or into the market. There are thus three main strands in recent land policy —more careful alienation, resumption for closer settlement, and land taxation.

Alienation.—Most of the land likely to be settled in the near future has been surveyed, and classified according to situation, character of soil or sub-soil, climatic conditions, extent of timber, etc. This classification vitally affects

	In 1901.	In 1920.	During Period 1901–1920.
	acres.	acres.	acres.
Area alienated	76,000,000	109,000,000	33,000,000
Area in process of alienation	35,000,000	57,000,000	22,000,000
Held under lease or licence	721,000,000	974,000,000	253,000,000
Total	832,000,000	1,140,000,000	308,000,000

the mode of tenure under which land may be allotted, the area of the holding, the use to which it may be put, the price or rent, the length of lease, the conditions as to residence, improvement, and payment of purchase instalments, the liability to invasion for settlement or resumption, and so forth. Further, the tenures are devised to fit the circumstances of the land-seeker. They are grouped in six main classes: (1) free grants, reservations and dedications; (2) sales by auction and special sales; (3) conditional purchases; (4) leases and licences; (5) closer settlement sales, leases, and licences, and (6) mining leases and licences.

The subdivisions in these classes are often great. New South Wales has 19 different types of lease in class 4, each to suit some special kind of land or tenant; Victoria has seven kinds of conditional purchase; and in all New South Wales has 36 different methods of dealing with land.

Of the various tenures one or two call for comment. Free grants, except for public or special purposes, are very rare. Queensland and Western Australia have offered free homesteads, subject only to residential and improvement conditions, but the results have not been very satisfactory. Sales by auction still survive in most States. But the popular method of alienation is conditional purchase, the conditions consisting usually of an initial deposit, a certain period of residence during the early years, improvements of a certain value, and the payment of the balance of the purchase money over a period of 30 years or more. Leases are granted especially for regions that at present are fit only for pastoral or mining work. The holding varies in size according to the character and location of the leasehold, and in districts of very low rainfall may run to hundreds of square miles. These leases are often for a long term, say 21 or 42 years; sometimes the rent is subject to re-assessment every 5 or 7 years. But leasehold tenure has in some States been used as a substitute for freehold. The Labour party opposes all further alienation of crown lands; it therefore stopped the further granting of freehold in the Northern Territory in 1912, and in Queensland in 1916. Henceforth land was to be leased only, either for a period in the case of large pastoral holdings, or in perpetuity when smaller areas of arable or dairy land were concerned. The perpetual lease, with periodic re-assessment of rent, satisfied in part the demands of advocates of land nationalization and of land taxation, for it kept the land in the hands of the State and allowed the community to annex some share of the unearned increment by revision of rents. Hence in some States perpetual leasehold tenure goes back as far as the eighties. But needy treasurers miss the revenue which would come from land-sales, and most perpetual lessees, especially on small homestead farms, long to secure the fee simple. Hence it is probable that the refusal to sell crown lands will hold only when and where Labour is the dominant influence.

Resumption for closer settlement.—The repurchase of estates is associated with (*a*) irrigation schemes, (*b*) the conversion of large pastoral freeholds into small dairy, grazing, wheat, or orchard blocks, (*c*) the settlement of returned soldiers. All States have passed legislation authorizing the government to buy estates to be cut up into blocks of suitable size, which are sold or let to settlers on easy terms. Usually settlers can obtain advances from the government with which to build homes or make improvements; and, where the land needs to be irrigated, the constructional work and the supply of water is undertaken by the State in return for a rent of so much per acre. This policy was inaugurated about 1900, and power to purchase land compulsorily has been granted in all States except Western Australia. The progress of resumption has been slow. By June 1923 4,150,000 acres had been purchased at a cost of £16,000,000 and 14,250 settlers had been established thereon. Some settlements have been successful; others after a hard struggle have ended in failure. Heavy initial costs, unsuitable land, and inexperienced workers have been among the causes of non-success. As part of the repatriation plans over 6,250,000 acres had by June 1923 been purchased or set aside out of crown lands for returned soldiers, at a cost of £28,000,000 and about 23,000 soldiers' farms had been allotted. Though it is still too early to estimate the results of this experiment, it is already evident that certain factors are militating against successful work, e.g. the character, inexperience, and lack of aptitude of some of the settlers, the high prices paid for some lands, the heavy costs of construction in irrigation centres, and the difficulty of finding markets. Most of the land was bought during a period of boom prices; material for construction was secured largely during the high-price period of 1918-1920. Hence the task of meeting interest and capital repayments may prove too heavy in a period of lower prices, and it may be necessary for governments to write down the value of the properties.

Land Taxation.—In spite of all efforts to build up a rural population, progress between 1890 and 1910 was slow. In 1911 New South Wales had 5000 more agriculturists, Victoria 1000 more, and Queensland 200 fewer, than in 1891. Between 1901 and 1911 the population of the continent grew by 18 per cent; the number of those engaged in pastoral pursuits rose by 36 per cent, but the number of agriculturists by only 4 per cent. The net immigration during the first 10 years of the century was only 40,000. Large estates grew in number, and in 1910 there were 1152 freehold estates of over 10,000 acres, with a total area of 30,600,000 acres; that is, 29 per cent of the land was owned in holdings of one acre or over.

To break up these large holdings, or to bring them into better use, was the aim of the federal land tax, imposed in 1910. Taxation of the unimproved value of land began in South Australia in 1884, and other colonies imposed the tax later

(New South Wales in 1895, Western Australia in 1907, Tasmania and Victoria in 1910, and Queensland in 1915). Local authorities had also been given power to levy rates on the same basis, so that with the coming of the federal tax three levies might be made on the same thing. The State taxes were mostly small (½d. to 1½d. in the £), but the federal tax was much more severe. Residents were exempted from taxation for the first £5000 of unimproved value; absentees had no exemption. The rate of tax ranged from 1d. up to 6d. (the rate on unimproved values exceeding £80,000), with an extra penny on the land of absentees. In 1914 the tax was extended from freeholds to leaseholds, and in 1914 and 1918 the rate was increased to raise more revenue for the war. Hence a Queensland estate worth £200,000 unimproved value paid in 1919 about £10,500 in State and federal land tax; a South Australian estate of the same value paid £6900. Quite apart from local rates, large estates might be paying an annual capital levy of 3 to 5 per cent on the unimproved value of the property.

The federal land tax has achieved part of its purpose in breaking up very large holdings; at the same time it has provoked a battle of wits between the taxpayer and the taxgatherer. It has led to much costly litigation on matters of interpretation and valuation, and many large owners have evaded the full weight of the tax by dividing their property among the members of their family, while really keeping the control still in their own hands. Where estates have been sold, the price obtained has usually been satisfactory to the vendor, but those who declined to sell have been able to meet the heavy taxation because of the good prices ruling (especially for wool) since 1914. Between 1910 and 1918 land with a total unimproved value of £63,000,000 (about one quarter of the land originally subject to tax) passed out of the taxable field into estates worth less than £5000 unimproved value. How much of this movement was due to family transfers, made in order to avoid taxation, cannot be ascertained, but certainly much land was affected in that way. Many large holders disposed of large tracts; in fact, during those eight years owners of estates in the class worth over £50,000 unimproved value got rid of land worth £28,000,000 unimproved value, and bought only £5,000,000 unimproved value. Absentee owners reduced their holdings by about half, and many resident smaller owners seem to have taken steps to put themselves below the tax-line. Between 1910 and 1920 the number of estates of over 20,000 acres fell from 431 to 349; the number between 5000 and 20,000 acres rose from 1592 to 2114, and the number between 500 and 5000 acres rose from 32,657 to 45,763. The very large holdings are steadily disappearing; the medium and large estates hold their own, or increase; the smaller ones increase rapidly. These figures do not, however, indicate fully what is happening. There are two contrary movements. On the one hand small men sell out to neighbours who are keen on acquiring larger holdings, possibly in order to turn arable into pasture land; often the blocks thus sold have been obtained by the vendor on conditional purchase, from crown lands or resumed and subdivided estates. On the other hand, very large holders may divide up their estates either among their children or among share-farmers, or may sell them outright to the government for closer settlement. Thus while land alienated in small blocks is being swallowed up in new large estates, older properties are being cut up for men who may eventually sell them to a new would-be large owner.

The attractions, economic and social, of city life draw rural dwellers away from the country. Retired farmers settle in the suburbs of the metropolis, the young folk flock to its shops, factories, and offices, and the countryside fails to retain its natural increase of population. To check this flow, by building up rural industries and by enhancing the social attractions of country life, is one of the big problems confronting the nation to-day. Again, settlement has, in the older States of the south-east, reached the limits of land suitable for cheap extensive exploitation. Western Australia and Queensland have still large areas of crown land suitable for selection; elsewhere further progress depends upon the closer settlement and more intensive cultivation of lands already in use, and the expenditure of large capital sums on roads, railways, and water conservation schemes to make semi-arid areas 'safe' for the small man. New South Wales discovered in 1923 that she must spend nearly £20,000,000 to settle 6000 new farmers; Victoria and South Australia can find room only by large resumptions. Thus Australia must either turn to its semi-tropical and tropical regions for areas on which to place fresh population, or must adopt and extend intensive treatment of those more fertile areas in the south which are already in private hands.

For a detailed account of contemporary legislation, application should be made to the crown lands departments of each State for copies of land laws in force, and explanatory pamphlets. See also the annual *Reports* of these departments. A more general survey will be found in the current issue of the Commonwealth *Year Book*. For a historical survey see Sir T. A. Coghlan's *Labour and Industry in Australia*; Nos. ii and iv of the Commonwealth *Year Books*; *Australia, Economic and Political Studies* (edited by M. Atkinson); Collier's *Pastoral Age in Australasia*; R. C. Mills's *Colonization of Australia*; and S. H. Roberts's *History of Australian Land Settlement*. For land taxation, see the annual *Reports* of the federal commissioner of taxation, and the fourth *Report* of the federal royal commission on taxation (1923).

H. He.

Land Planarians, a group of Turbellaria (see FLAT-WORMS), whose habitat is defined by their name. In other countries planarians are usually dealt with as a whole—many genera inhabiting fresh or salt water—but the abundance and variety of the land-inhabiting genera found in Australia justifies separate treatment in this case. Nowhere else can more species, or more individuals, be found; it is probably because of their softness, and the consequent difficulty of handling and preserving them, that they have attracted the attention of so few naturalists. The mere finding them is easy; they occur in gardens and parks, in bush clearings and uncleared scrub, wherever a little cover is available.

Each of the Australian States possesses a number of endemic species. In Victoria the magnificent *Geoplana spenceri*; in Western Australia *G. fusco-dorsalis* and *G. arenicola*; in New South Wales *G. quinquelineata* and *G. ponderosa*; in Queensland *G. regina, G. parva* and *G. scaphoidea*; in Tasmania the classic *G. tasmaniana* (originally collected and described by Darwin), *G. typhlops, G. dovei, G. lyra,* and others; are peculiar to these States, and have not been found elsewhere. In general character the Tasmanian species resemble those of Victoria more than those of the other States; the planarians of New

(1) *Geoplana ponderosa.* (2) *G. Mortoni.* (3) *G. Hillii.* Below each is its cross-section.

Zealand are of a type quite distinct from the Australian species.

In Australia land planarians are found chiefly under logs and pieces of wood that may be lying about in paddocks adjacent to scrub. In the scrub itself they are not so readily found, because of the larger amount of available shelter, and because the insects on which they prey are more abundant under logs in the open. Like other creatures of similar habit, they occur most plentifully where the soil is rich and moist. During wet weather they are to be met with under leaves, and even crawling about in the open daylight. Some species burrow freely, and seem quite at home in the soil associated with earthworms. For the most part they are carnivorous, feeding upon a great variety of insects, and even on molluscs and earthworms, while occasionally some species will devour others. Several different species, however, both of *Geoplana* and *Rhynchodemus*, have been observed feeding on peaches, strawberries, apples, and other fruits, and on bran that had been laid as a trap for slugs. Their method of securing their prey is to crawl over it, and thus entangle it with a sticky mucus freely secreted from the surface of their bodies. The trumpet-like suctorial tube is then protruded from the peripharyngeal aperture and inserted into the captive's body, and the soft parts of the latter are quickly transferred to the alimentary canal of the planarian. The peripharyngeal aperture is usually situated about midway on the ventral surface, and the genital aperture about midway between this and the posterior end.

In land planarians that have more than two eyes these organs are usually very numerous, amounting in some cases to several hundred. They consist of minute black dots, scarcely visible to the naked eye, extending in a single row round the edge of the anterior tip, usually expanding into a more or less crowded group on each side just behind the anterior tip, and then thinning out to a single row on either side which may extend to the posterior end. In some species there is little or no side-grouping, the eyes being arranged in a single row extending backwards to a variable distance. Planarians possessing two eyes only (*Rhynchodemus*) have them situated one on either side, just behind the anterior tip. The eyes appear to possess no true vision, but are merely sense-organs, allowing the animal to avoid the light when it so desires. When moving about they hold up the anterior end, curve the sides downwards so that a cross section would have the outline of a horseshoe, and delicately sweep the tip about, gently touching any object that may be in the way. Associated with the eyes are numerous minute ciliated pits which appear to have a sense analogous to that of smell.

Though nocturnal in their habits, land planarians move about in daylight during dull moist weather. They are hermaphrodite, the male and female organs opening into a common genital atrium. Specimens are frequently met with having a large swelling just behind the genital aperture, caused by the presence of an egg-capsule. This is a round or oval body with a chitinous shell, smooth and shining, and of a brown colour while in the uterus and for a day or so after laying; afterwards it turns to a shining black. The normal method of laying the capsule appears to be through a rupture of the dorsal tissues, through which the capsule passes; the wound so formed heals quickly.

During periods of drought planarians burrow in the soil, and construct hollow globular cells in which they lie dormant until favourable conditions again prevail.

T.S.

Landsborough, WILLIAM, third son of David Landsborough the Scottish naturalist, was born at Stevenston in Ayrshire, and while still very young migrated to New South Wales and took up pastoral work in New England. In 1853 he went north to the Burnett district, and in 1854 took up a run on the Kolan River W. of Bundaberg; in 1856, finding his run unprofitable because of drought and hostile blacks, he began to investigate the northern area of the Fitzroy watershed (the Isaac River), passing to the southern area (the Comet River) in 1858, and in the next year crossing the main range to the head-waters of the Thomson. He was therefore well known as an expert bushman when in 1861 the Queensland authorities decided to send out a party in search of Burke and Wills, and chose him to head the party. His work on this expedition is described under EXPLORATION BY LAND. He was unjustly accused of forgetting Burke and Wills in his desire to discover new pastoral country, but was honoured and rewarded for his achievement both in Melbourne and by the Royal Geographical Society. After visiting India and Europe, he returned to Queensland, and in 1864 was nominated to the legislative council, but the next year took the position of government resident in the Burke district at the southern end of the Gulf of Carpentaria; here he moved the official headquarters from Burketown (which he found unhealthy) to Sweers Island off the coast. His love of exploration, however, was unabated, and during his stay in the north he investigated the head-waters of the Diamantina and its tributary the Western River. In 1869 he left the residency, some years later was given a minor official appointment near Brisbane, and in 1882 received a grant of £2000 for his services as an

explorer. He died at Brisbane on 16 May 1886.

Lane, WILLIAM (1861-1917), born in Bristol on 6 September 1861 and educated at the Colston grammar school in that city, left England for Canada at the age of 14 and, after some hardships, found his way into the composing-room of a newspaper office. He practised journalism in both Canada and the United States, and in 1883 migrated to Australia. There he worked for most of the leading newspapers, but was especially connected with the *Brisbane Courier*; this he left to edit a weekly journal, *The Boomerang*, of which he was part-proprietor. He was much interested in the Labour movement, and through the *Boomerang*, various pamphlets, and debating circles reached not only the artisans and mechanics of Brisbane but also miners and shearers in the backblocks, familiarizing them with the doctrines of Marx, Belfort Bax, Bellamy, and Henry George. His influence became still more dominant when in March 1890 he established the Queensland *Worker*, the first Labour paper in Australia, on the basis of a regular subsidy from the trade unions, the paper being thus made independent of advertisements. Its motto was 'Socialism in our time.' Lane had been largely responsible for the formation in 1889 of the Australian Labour Federation—whose platform marked a distinct advance towards state socialism—and this brought him in close touch with the Labour organizations of the various colonies. He was instrumental in raising £30,000 to assist the London dockers' strike of 1889-90, and actively organized the maritime and pastoral strikes of 1890-1. In 1892 he wrote under the pseudonym 'John Miller' a novel, *The Working Man's Paradise*, to assist the fund which was being raised for men imprisoned as an outcome of the shearers' strike. But he was by this time convinced that neither political nor industrial action could bring about 'socialism in our time' with society constituted as it then was. He therefore developed plans, which he had been considering for some years, for the establishment of a utopia in a virgin land by ardent disciples of the new faith. Three experienced bushmen whom he had sent in search of a suitable country for the experiment reported very favourably on Paraguay, where they were warmly received by the authorities, and promised a free grant of 450,000 acres of agricultural and grazing land. Meanwhile the 'New Australia Co-operative Colonization Society' had been organized by Lane and his supporters, and the *New Australia Journal* established to further the scheme. The society was to be based on communal ownership and control of the means of production, exchange, and distribution; communal saving of all necessary capital; marriage; the maintenance of children by the community under the guardianship of the parents; equality of the sexes; and non-recognition of any special religious creed. In a short time £30,000 was paid into the coffers of the association. Each prospective male member of New Australia was obliged to pay at least £60 into the general fund, and those with more were expected to contribute all they had. Lane gave £1000, others as much as £400. The sailing-vessel *Royal Tar* (600 tons), purchased for £1620, left Sydney on 16 July 1893 with the first party—209 passengers and a crew of 32, all members of the association. But even during the voyage there was dissension. It was provided by the constitution of New Australia that decisions should be made by a two-thirds majority; since the members who remained in Sydney had vested their authority in Lane, he could dictate as he liked to the party aboard ship. This was resented, especially on one occasion when he ordered the women to remain in their cabins after dark. Another cause of trouble arose after the arrival of the ship at Monte Video on 13 September. The members had pledged themselves to teetotalism until the initial difficulties should be overcome, but at Monte Video some of them obtained liquor. This was not only a breach of the pledge, but also demonstrated that the delinquents had retained private moneys, contrary to the fundamental rule of the association. Some measure of harmony was restored, and the party proceeded upstream to Asuncion and thence, via Caballero, to the site of New Australia, which was reached with difficulty on 4 October. The government of Paraguay constituted New Australia a separate district—thus removing it from the control of local magistrates—and in order to secure local autonomy appointed to official positions three nominees of the colonists. Lane thus became a magistrate and administrator of the colony. Unfortunately the party was ill-equipped with the necessary implements, and many of the members were ill-suited to the work, though all had been carefully selected before leaving Sydney. They were plagued with strange insects; they had to construct their buildings of adobe (bricks of unburnt mud)—a material generally used in South America and well suited to local conditions, but unfamiliar and disheartening to Australians; complications arose in connection with the distribution and use of the communal income, and it was evident that hardships were imminent as soon as the capital fund was expended. Men accustomed to a roving life found their new employment monotonous, and sought diversions elsewhere. Three visited a neighbouring village and got drunk, and Lane decided, despite many objections from other members, that the offenders must be expelled. Using his authority as a magistrate, he brought Paraguayan police to the settlement to effect the expulsion. When the men left, accompanied by some of the protesting families, they had only £3 each wherewith to meet the future; this caused a definite split in the colony, and 85 members seceded in a body. The British consul at Asuncion, unable to provide for all these destitute people, tried in vain to patch up a truce between them and Lane. Most of them were finally repatriated to Australia.

Meanwhile a second party had sailed from Adelaide on 31 December 1893. They had heard the news of the secession, but in a mistaken form (the cabled message mentioned 8 seceders, instead of 85), so they were not disheartened. On their arrival in New Australia they were met by Lane, and taken to a site about ten miles from the original settlement. A second crisis arose when the newcomers under Gilbert Casey insisted on a change of leaders. Lane bowed to the general desire, telegraphed to his associates in Australia for power to reinstate the democratic constitution—which had been suspended before the first party left Sydney—appointed a chairman with a board of management, and then left New Australia with 45 adult sympathizers, 12 children, some implements and a few cattle. He applied to the government for a further grant of land, but the

only land offered, after two months' waiting, was in an unsuitable district without access to market. Fortunately, one of his followers—David Russell Stevenson, a cousin of Robert Louis—received from Scotland a legacy of £150, which served as a deposit on the purchase of 5½ leagues of good land at Caazapa, and there the Cosme colony was founded in July 1894. During the first two years the little band of idealists suffered great hardship, the payment of the annual instalments being a big tax on their resources. Nevertheless they continued to compile 'a written witness of their unfailing cheerfulness for the edification of future Cosmans'—the *Cosme Evening News*. On 25 June 1896 the government of Paraguay, satisfied as to the good faith of the Cosmans, paid the balance of the purchase-money on the land (£200), reimbursed them what they had already paid, and extended their territory another league. The only condition attached to the grant was that 72 families must be settled on the land within two years.

At the time there were 50 men and 20 women in the colony. This disproportion between the sexes was in itself a serious problem, and Lane feared that the bachelors might yield to temptation and take wives from among the graceful and industrious native women of the neighbouring districts. To meet official demands, and also to correct this disproportion, he decided to visit England on a recruiting campaign, with the object of securing 22 married couples and 30 single women as a minimum. He sailed for England in September 1896, having first arranged with the Paraguayan government to grant assisted passages to the selected colonists and to establish a Cosme agency in the Paraguayan consulate at London. A number of recruits were despatched to the colony from England, but their arrival led to jealousy and strife, with the result that many of the newcomers and some of the old members abandoned the settlement; consequently on his return Lane found Cosme weaker in numbers than when he left it. In 1899 he vested his authority in his brother John, and abandoned the task he had undertaken with such high hopes six years before; he remitted money, however, until—following the introduction of native labourers on a wage-system—the settlement lost the character of a co-operative commonwealth. He also set himself to repay to all who had left the colony, and who claimed a refund, the amounts they had originally paid into the funds; and he was still doing this at the time of his death.

After leaving Paraguay Lane visited New Zealand, and joined the staff of the *New Zealand Herald* as a leader-writer. In a few months he resigned this position in order to re-establish the Sydney *Worker*, but his Imperialist views, especially on the issue of the South African war, proved unacceptable to his associates. He therefore in 1900 severed his connection with Australian Labour politics and returned to the staff of the *New Zealand Herald*. He became editor of the paper in October, 1913, and retained that position till his death. During his long connection with the *Herald* he wrote under the pen-name 'Tohunga' weekly articles, many of which have been collected and published in book form. He also interested himself in defence policies, and was chiefly responsible for the organization of the National Defence League in 1906. On the outbreak of war in 1914 he associated himself with the Auckland Soldiers' Club. He died on 26 August 1917.

Lang, JOHN DUNMORE (1799-1878), born at Greenock in Scotland on 24 August 1799, entered the university of Glasgow at the age of 12 (M.A., 1820; D.D., 1825) and received his licence to preach from the presbytery of Irvine on 1 June 1820. Hearing from his brother George, who had taken up a grant of land in New South Wales, that the moral condition of the colony was shocking, he determined to establish Presbyterianism therein and for that purpose was ordained by the Irvine presbytery on 30 September 1822, left Leith in the *Andromeda* on 14 October, and arrived in Sydney (via Rio de Janeiro and Hobart) on 23 May 1823. His family followed in January 1824. At the time the only Presbyterian church in the colony was that built by a group of devout Scots at Ebenezer on the Hawkesbury river; Lang was therefore obliged to hold his Sydney services in the court-house, which was lent to him temporarily by the governor. On 1 July 1824 the foundation-stone of the Scots church on Church Hill was laid; financial assistance to meet the expenses incurred in connection with the new building was refused by Governor Brisbane, whose sympathies had been alienated by Lang's indiscretion and vindictiveness, but was subsequently granted by the colonial office up to an amount not exceeding one-third of the estimated cost. With Lang's consent this arrangement was altered shortly afterwards, a regular salary for the minister being substituted for the grant; before, however, official information of the change was received in Sydney, the colonial treasury had contributed 2400 Spanish dollars to the building fund, and though the colonial office directed Darling to insist on repayment there is no record of any refund. The Scots church, over which Lang was to preside as minister until 1878, was opened on 16 July 1826.

Indefatigable in his efforts to raise the moral tone of the community, Lang next turned his attention to education. Having determined to establish a Presbyterian college in Sydney 'to afford the youth of the colony a liberal, efficient and economical education,' he again visited England to secure the requisite financial assistance. The colonial office at first agreed that £3500 should be advanced to him in instalments as the building progressed, but this arrangement was modified at a later date to permit the use of part of the money to defray the cost of transporting to the colony 100 Scotch mechanics and their families, who arrived in Sydney with Lang on 13 October 1831. The scheme met with considerable local opposition, partly because Lang was suspected of stealing a march on the two King's schools (see SCHOOLS) which were being planned, and partly because he had roused the anger of the Anglican community by proposing that money for subsidizing the migration of poor agricultural families from England to the colony might be raised by the gradual sale of the lands of the Clergy and School Corporation—which, he alleged, were grossly mismanaged. Consequently, to meet liabilities incurred by the introduction and temporary maintenance of the mechanics (of whom, by the way, Bourke spoke highly) Lang was forced to sell his personal property. Nevertheless the new college building was completed in 1835, and was at once occupied, classes having been opened two years earlier. For the subsequent history of the college see SCHOOLS. Since 1833 Lang had also sought help to establish parish schools in connection with each

Presbyterian congregation throughout the territory.

Meanwhile he continued his ministerial work. A number of ministers having been introduced into the colony through his instrumentality, the first presbytery of New South Wales was formed in 1832, and in 1835 he organized a presbytery in Tasmania. Being dissatisfied with the number and character of preachers available, he returned to Scotland in 1836 to secure more recruits. On 3 September 1837 he again reached Sydney with eight Presbyterian ministers and four probationers; but, as the local presbytery held that only ministers in charge of congregations could under the terms of a recent declaratory act of the Church of Scotland become members of that body, the recruits could neither take part in the presbytery's deliberations nor claim allowances from the colonial treasury until they received a 'call.' Lang, who had already denounced some resident ministers for dissolute conduct, now proceeded, with nine other clergy, to form a new synod claiming authority over the Presbyterian Church in the colony; whereupon the acting-governor (with the advice of his executive council) refused to make any allowance from public funds to members of the synod other than Lang—who was already in receipt of a salary. Until 1840 Presbyterianism was divided against itself. In 1839 Lang again went to Great Britain on behalf of the synod, but accomplished nothing; the colonial committee of the general assembly of the Church of Scotland considered the journey unnecessary, and the colonial office refused to give him the usual half-pay during his absence. Before his return the schism was healed, the two bodies amalgamating in 1840 under the title of the 'Synod of Australia in connection with the Established Church of Scotland.' On his return Lang was admitted a member of the new synod, and at once proceeded to Port Phillip and Tasmania to gain support for the new doctrine of dissociation of church from state. The synod admonished him for his frequent absences from duty; he threatened to leave the colony, but finally agreed to remain with his Scots church congregation on condition that they broke all connection with the state and dissociated themselves from the synod. For this decision Lang was deposed by the synod, whose decision was confirmed by the presbytery of Irvine. Once again Lang went back to Scotland, laid his case personally before the Church authorities, and returned to the colony fully accredited as an ordained minister of the Church of Scotland; but his deposition was not rescinded by the local synod until 1863.

One service which Lang rendered to the colony during this period was the introduction of three German (Lutheran) missionaries with assistants to establish a mission-station for aborigines at Moreton Bay. He next interested himself in politics, and in 1843 took his seat in the new legislative council as one of the six representatives for the Port Phillip district. From 20 August 1844 (when he moved a resolution for the speedy and entire separation of Port Phillip from New South Wales) until Victoria became a separate colony, he took a prominent part in the separation movement. He also interested himself in immigration, and to counterbalance the effect of the continued introduction of poor Irish farmers decided to encourage settlers from Scotland. A tour of inspection made in 1845-6 through the Port Phillip and Moreton Bay districts convinced him that the Port Phillip district, if opened up by a railway, would be eminently suitable for agricultural development, and that a large inflow of migrants could be absorbed immediately at Moreton Bay if they set themselves to cotton cultivation on small holdings (see COTTON). In his opinion the cotton crop would prove the best means of establishing the group settlements he had in mind. Having resigned his seat in the legislative council, he again proceeded to Great Britain, and on arrival published two books (prepared during the voyage) setting forth the attractions of 'Phillipsland' (the Port Phillip district) and 'Cooksland' (the Moreton Bay district). He succeeded in organizing a group of about 600 'virtuous' migrants, who proceeded to the colony on the understanding that they would receive, on arrival, grants of land equivalent in value to the cost of their passage out. The colonial government, however, refused to comply with this arrangement, and the experiment involved Lang in many difficulties and great expense.

On his return to Sydney Lang again entered the legislative council as a member for Sydney, and acted on different occasions as an intermediary between the anti-transportation league (see TRANSPORTATION) and the government. In 1854 he was returned to the council as a member for Stanley (Moreton Bay) and at once threw himself wholeheartedly into the growing agitation for separation from New South Wales. Separation and federation were essential steps in the realization of his political ideal—Australian independence of Great Britain. This he had already embodied in *Freedom and Independence for the Golden Lands of Australia*, which was written in 1852 during his seventh voyage to England. His free and united Australia was to consist of seven provinces: South Australia, Victoria, Tasmania, New South Wales, and three new provinces to be carved out of the northern districts—'Cooksland,' 'Leichhardtsland,' and 'Flindersland.' Leichhardtsland and Flindersland he subsequently renamed 'Capricornia' and 'Carpentaria.'

Lang was unable to contest the first elections under responsible government owing to a clause in the Imperial statute which made ministers of religion ineligible for a seat in the legislature; in 1859, the clause having been repealed in the meantime, he was returned to the assembly and retained his seat until 1869, when he abandoned active politics. During his political career his interest in education never flagged; he also advocated a liberal franchise, land reform, triennial parliaments, postal reform, and the abolition of state aid to religion.

Throughout his career he was an indefatigable pamphleteer, and found time also to write numerous books, usually of a highly controversial nature. Several of these have been already mentioned; the following list (which is merely a representative selection) will give some idea of Lang's many-sidedness:—*Aurora Australis* (poems, 1826), *Origin and Migrations of the Polynesian Nation* (1834; 2nd edition, 1877), *Historical and Statistical Account of New South Wales* (1834; other editions, 1837, 1852, 1874), *Religion and Education in America* (1840), *Freedom and Independence for the Golden Lands of Australia* (1852; 2nd edition, 1857), *Queensland, Australia* (1861), *The Coming Event*, an enlarged reprint of *Freedom and Independence*, (1870), *Poems, Sacred and Secular* (1873). In 1835-40 he published *The Colonist*, a weekly journal in which he discussed questions of the day with a vigour that frequently brought

him into collision with the government. On 7 October 1841 he issued the first number of *The Colonial Observer* (which was in 1845 taken over by Anglicans and became *The Sentinel*), and in October 1851 produced *The Press*, which lasted until his departure for England in 1852. During the seventies he devoted most of his failing energy to his ministerial work, and in 1872 (the year of his ministerial jubilee) was made moderator of the general assembly of the Church in New South Wales. He died on 8 August 1878.

La Pérouse, JEAN-FRANCOIS DE GALAUP, COMTE DE (1741-1788), was born at Albi in the province of Languedoc on 23 August 1741. The name by which he is known to history is derived from Peyrouse, one of the family estates, but he never used the full 'de la Peyrouse' which was his right, preferring to sign himself 'Lapérouse,' as his descendants do. His desire for a naval career showed itself at an early age. He read many accounts of voyages and travels, and his imagination was specially kindled by the discoveries of the English Anson, the South Sea explorations of Louis de Bougainville, and the work of Byron, Carteret, and Wallis. The chief influence upon his mature mind, however, was that of James Cook. One of the most moving passages in Lapérouse's *Journal* was a eulogy of Cook, prompted by a visit to the island where the great English sailor met his death; and when, shortly before he sailed on his last voyage, Banks sent him from England two magnetic needles which Cook had used, he acknowledged that he received them with 'feelings bordering on religious veneration for the memory of that great and incomparable navigator.' His father supported his wish to go to sea, and in November 1756 he entered the French Marine as a royal cadet, commencing active service in the following year on board the line-of-battle ship *Celèbre*. From that time until his death 31 years later he was almost continuously afloat. Up to 1763 he was in the thick of the naval war. In the battle of Quiberon Bay (November 1759) he was aboard the French flagship *Formidable*, which was captured, and spent a short time in England as a prisoner of war. In 1775 he was in the East Indies, and in the Mauritius met the girl whom he afterwards married; from 1778 to 1782 he served on the coast of North America under D'Estaing and Latouche-Treville. By 1785 he was a post-captain with an excellent record; he had attracted the attention of de Castries, the minister of marine; and when Louis XVI needed a gallant and able man to command an expedition of special importance, Lapérouse was the obvious choice.

In 1785 Louis XVI (who also was much interested in voyages of discovery) decided to fit out an expedition of exploration to the South Seas, western America, and eastern Asia. The king's study of Cook's voyages had convinced him that there was a large amount of original work still to be done in those regions. At his direction, therefore, a plan of research was prepared by Charles Claret, Comte de Fleurieu, a well-known writer on geography and navigation. Two ships of the navy, renamed *La Boussole* and *L'Astrolabe*, were selected and the command given to Lapérouse. The instructions given him were both precise and lengthy. He was to round Cape Horn, visit various island groups on his way across the Pacific, investigate the Louisiade group off eastern New Guinea, pass Endeavour Strait, examine if possible the Gulf of Carpentaria, and then coast Australia west-about to the southern end of Tasmania. Thence he must follow Tasman's tracks to Cook Strait in New Zealand, cross the Pacific to the western coast of North America, and return to Europe via the China Seas, the Philippines, the Moluccas, and Timor. It will be noted that the eastern coast of Australia—the part skirted by Cook—was deliberately omitted; Louis, who admired Cook as much as Lapérouse did, was loth to do anything that might seem to threaten his work, even his annexation of New South Wales for Britain.

Sailing from Brest on 1 August 1785, the expedition rounded Cape Horn in January 1786, and, after spending some weeks on the Chilian coast, visited Easter Island (April) and the Sandwich group (May). Here Lapérouse seems to have decided (as he had permission to do) that the arranged route could profitably be reversed. He went directly north to Alaska (June to August), ran down the western shores of America to California (September), and thence struck westwards across the Pacific to the Ladrones (December), Macao (January 1787), the Philippines, Formosa (April), Japan (May), and Kamchatka. Here the drawings and journal up to date were packed up and sent to France overland in charge of J. B. B. de Lesseps (the only member of the expedition who ever returned to Europe), and letters received from France informed Lapérouse of the British expedition to Botany Bay and bade him visit the new settlement. He next sailed for the southern Pacific, reaching the Samoan group early in December. At Tutuila (which he knew as Maüna) a tragedy occurred. Captain de Langle, commander of the *Astrolabe*, went ashore with a party to obtain fresh water, was attacked by natives, and killed; 11 of the crew shared his fate, and 20 others were wounded. The loss of the services of 32 men was a serious embarrassment, and Lapérouse determined to make straight for Botany Bay to get wood and water, and to put together two new longboats to replace those destroyed at Tutuila. Norfolk Island was reached in January 1788, but no landing was made. On 24 January the two French vessels were beating up off Solander Point. Only six days earlier Phillip had arrived in Botany Bay. At the moment when the foreign flags were sighted by the English, Phillip was about to set forth in the *Supply* to Port Jackson. Heavy weather prevented Lapérouse from entering the bay till the morning of 26 January; when at length his ships came to anchor, Lieutenant King of the *Sirius*—on behalf of Captain Hunter, who was just about to convoy the fleet round to Port Jackson—paid a visit of courtesy to the *Boussole*. Lapérouse had heard at Kamchatka that the British intended to found a settlement in New Holland, but had no idea what progress they had made. He told Paterson that he expected to find a town built. Instead of that he found Phillip abandoning the site first chosen—an action with which, after some experience of the bay, he cordially agreed.

Phillip and Lapérouse did not meet, but other British officers paid friendly visits to the French, and mutual relations were unexceptionally cordial. In his conversation, as in his writings, Lapérouse lost no opportunity of expressing admiration for the person and work of Cook. The *Boussole* and the *Astrolabe* sailed from Botany Bay on 10 March. From that moment they disappeared from view, and all

trace of them was lost for nearly 40 years. A search expedition in command of Dentrecasteaux, despatched from France in 1791, failed to solve the mystery, and it was not until 1826 that Captain Peter Dillon (q.v.), sailing from Valparaiso to Pondicherry in the *St. Patrick*, called at Tucopia (Barwell Island) and was put on the right track. Dillon's curiosity was aroused by an old silver sword-hilt, sold to a member of his crew, and he elicited the information that this and other relics were obtained from Vanikoro in the New Hebrides. At the end of the year Dillon was sent from Calcutta in the *Research* to make a systematic search of that locality; and his investigations left no doubt that Lapérouse's ships had been driven ashore there by a storm in 1788 and totally wrecked, and that a few survivors who attempted to escape in a boat were also drowned. Dumont-Durville in a new *Astrolabe* in 1828 made additional discoveries. The relics of Lapérouse are now exhibited in the Marine Museum at the Louvre, in Paris, and his memory has been kept fresh in Australia by the maintenance of a monument, erected by Bougainville in 1825-6, on the site of the French camp. This site was set aside by Brisbane for the monument and for a tomb over the grave of Father Receveur (q.v.); in 1880 Captain Mathieu of the French navy tried to purchase it, but the needs of coastal defence prevented the alienation. On 14 July 1917 the New South Wales government announced that it had been given to the French nation in perpetuity. E.S.

Laportea, a small genus of the family Urticaceae, widely distributed (especially in Malaysia), consisting of trees or shrubs with rigid, stinging hairs. The flowers are unisexual; the females enlarge after flowering and combine with the succulent flower-stalks. *L. gigas* (Stinging Tree or Giant Nettle) known by the aborigines on the northern rivers of New South Wales as 'irtaie,' secretes a poisonous fluid, very powerful in the young leaves, whose sting is exceedingly virulent and infuriates cattle. Juice from the leaves or stem of the cunjevoi (q.v.), or slices of the stem of the stinging tree itself, are usually applied as antidotes. The bark yields an excellent fibre of good colour. The inner bark is beaten into a coarse cloth similar to the tapa cloth which South Sea islanders make from the Paper Mulberry (*Broussonetia papyrifera*). The best and strongest fibre is obtained from the root-bark; from this, after chewing it, the aborigines make fishing-nets and lines.

Larks and Pipits, perching birds, terrestrial in habit, belonging to the families Alaudidae and Motacillidae. The true larks (Alaudidae) are represented in Australia by one or more species of the genus *Mirafra* (known as bush-larks), and by the introduced European Skylark (*Alauda arvensis*) which is thoroughly acclimatized in the outskirts of Melbourne and Sydney. Bush-larks range from Africa through southern Asia and the Malay Archipelago to Australia. They are rather small birds, with mottled brown plumage, lighter underneath, with dark spots on the breast. They frequent open grassy or heathy country, running when on the ground. The song, which is a fine one, uttered on the wing high in the air, is not infrequently heard on moonlight nights as well as in the daytime. The nest is a partially-domed structure of dry grass, built in a hollow beneath a grass-tuft. The three eggs are greyish-white, marked all over with brown and purplish spots. One species (*M. javanica*) is found throughout Australia and extends to Java. Specimens from the north-west of the continent are often smaller and

Lark (*Mirafra javanica*).

much more rufous in colouring, and are regarded by many authors as a distinct species (*M. woodwardi*).

The Australian Pipit (*Anthus australis*)—generally called 'ground-lark'—is, though a member of a distinct family, surprisingly like the bush-lark. The genus to which it belongs is probably more universally distributed over the globe than any other genus of birds, and our species resembles the majority of its congeners in plumage and habits. It frequents open country, especially grass-lands, and, owing to the clearing of the bush over wide areas, is undoubtedly becoming more and more common. Its nest is a cup-shaped structure of grasses, built at the base of a grass-tuft; the eggs closely resemble those of the bush-lark. In the breeding-season it utters a pretty song, rising up as it sings to some height in the air, and performing part of a circle before descending.

The true wagtails of Europe, which belong to the same family (Motacillidae) as the pipits, are quite unconnected with the Australian wagtail, which is one of the family of flycatchers (q.v.). A single specimen of a true wagtail was shot in 1905 on the Dawson River in south-central Queensland, and proved to be an example of the variety of the Yellow Wagtail (*Motacilla flava*) which breeds in Kamchatka and winters in China and Malaysia. As it was obtained in June, the season when it should have been in Kamchatka, it had probably travelled south instead of north from its winter quarters.

Other birds known in Australia as larks, but not belonging to either of the families dealt with above, are the song-larks, the subject of a separate article (q.v.), the field-lark, one of the warblers (q.v.) and the magpie-lark (q.v.). W.B.A.

Latrobe, CHARLES JOSEPH (1801-1875), born in London on 20 March 1801, was the son of a Moravian minister stationed in Yorkshire. He himself invariably spelt his name 'La Trobe;' the spelling adopted here is that used by his family before and after him, intermittently in official documents concerning him, and almost universally by his biographers. He received the education usually given to students for that ministry, but abandoned the profession shortly after he came of age, and led a roving life for about 13 years—travels in Switzerland (1824-6), the Tyrol (1830), and the United States (1832-5) occupying most of his energies. In 1834 he and Washington Irving crossed together the Texas prairies on a journey

from New Orleans into Mexico, and Latrobe published an account of it as *The Rambler in Mexico* (1836). As a result of this publication he was in 1837 commissioned by the colonial office to report on the administration of a fund intended to promote education among the West Indian negroes. In 1839 the colonial office, advised by Bourke that the rapidly growing settlements on Port Phillip needed the control of a resident official with the powers of a lieutenant-governor, offered the position to Latrobe, though the title was refused him. He reached Sydney on 26 July 1839, and after long consultations with Gipps reached Melbourne on 1 October and took up his duties as superintendent of Port Phillip. For a few months in 1846-7 he was in charge of Tasmania also. His administration lasted from 1839 to 1854—a period of exceptional difficulty marked by two grave financial crises (arising out of the land speculation of 1838-42 and the gold discoveries of 1851-2), and quite beyond the administrative control of an inexperienced man.

His first arrival, however, was greeted with rejoicings and panegyrics as well as with eager demands for reforms of all sorts. More especially did the residents of Port Phillip desire the expenditure of their own revenues on local improvements. In the six years ending in 1842 those revenues (including land-sales) exceeded local expenditures by £362,000, and of this surplus £158,000 was spent at the Sydney end of the colony. Latrobe (as the date just mentioned will show), although he sympathized strongly with the residents, did not easily obtain satisfaction for them: but in 1842 he secured from the unreformed New South Wales legislative council an act incorporating the town of Melbourne, which to some extent relieved the strain. Even this, however, did not restore his already waning popularity. He was in a very difficult position: he was neither a governor, answerable only to the distant colonial office, nor a lieutenant-governor nominally subordinate to Gipps but practically independent, but only a 'superintendent,' unable to make any important decisions without first obtaining the approval of Gipps—which during most of his term involved also the approval of a suspicious and often hostile legislature in Sydney. Lacking self-confidence, and deeply impressed with the ability and experience of Gipps, he was incapable of strenuous resistance—such as Port Phillip colonists expected—to any policy laid down in Sydney. Consequently he had less influence on the development of the settlement than any other official in a similar position before the institution of responsible government, and at the same time was more bitterly attacked for what he did not do than other governors for what they did. The history of Victoria under his nominal rule will be found in the article on that State: here we shall be concerned chiefly with matters in which he exercised some influence.

It was by his efforts, for instance, that a resident judge was appointed to Melbourne in 1841 (unfortunately the first man sent down was totally unfit for the position). In the movement for separation which occupied nearly the whole of the forties he was either negligible or a hindrance, since he felt that Port Phillip was not fit to be trusted with an elected council, and the New South Wales executive council consequently advised the colonial office in 1846 that only a nominee council should be granted. On one occasion, however, Latrobe (having been previously assured of Governor Fitzroy's backing) placed himself at the head of a popular movement and gained great credit thereby. On 8 August 1849 the convict transport *Randolph* dropped anchor in Hobson's Bay: on the 11th she passed the heads again on her way to Sydney without having attempted to land a single convict, and Latrobe was for a time the best-loved man in Melbourne. Though they attracted little attention at the time, his forethought in reserving from sale by auction the lands since known as the Fitzroy and Carlton gardens, and his establishment of the botanic garden on the southern bank of the Yarra opposite his own residence at Jolimont, are valuable results of his initiative where he could exercise it.

The burlesque election of Earl Grey as member for Melbourne in the New South Wales legislative council (1848) shocked Latrobe deeply, but he thankfully left it to be dealt with by Fitzroy. When the 'separation act' of 1850 was passed, Fitzroy summoned him to Sydney to help in the preparation of the necessary legislation, and it was partly by his advice that the act contained a provision which still dominates Victorian electoral law—the allotment of more representation to country districts, in proportion to population, than to the cities. In 1850 the discrepancy between town and country was 7 to 1: in 1924 it was about 2½ to 1. When separation became a fact, Latrobe was made lieutenant-governor of the new colony; but that comparative peace to which he might have looked forward was promptly made impossible by the gold discoveries which were publicly announced ten days before his formal admission to the new office. The effect of these discoveries on Victoria is narrated under GOLD, DISCOVERY OF; on Latrobe their effect was to distract him beyond measure. He began by copying the New South Wales regulations, which did not at all suit the circumstances of Victoria: every attempt he made to procure money for strengthening the forces of law and order was thwarted either by the new legislative council or by a defiant public opinion: the vehemence on the one hand of the squatters, who demanded immediate survey and undisturbed possession of their runs, and, on the other hand, of the diggers who claimed the right to enter any area in search of gold and to have good land thrown open to them whenever they should decide to settle down as farmers, kept him hesitating between two claims equally just and at the moment equally inexpedient: and his known dislike of the measures which the council took to prevent the immigration of convicts from Tasmania did but emphasize the animosity with which nearly all classes of the community now regarded him. Latrobe struggled on, anxious only to reconcile the dictates of his conscience with the immediate necessities of keeping the peace and maintaining the administration; but, when early in 1854 he received from the colonial office a snubbing and unsatisfactory reply to a despatch of September 1852, he resigned office and left the colony on 5 May. The rest of his life he spent in retirement in England, dying at Litlington near Eastbourne in Sussex on 2 December 1875.

Apart from his much troubled political career Latrobe was active in providing Melbourne with many institutions of great value. He helped to establish the Melbourne hospital, the public library, the benevolent asylum, and the university, and strongly backed, if he did not initiate, the Yan Yean water-supply scheme. He was probably the best-intentioned governor who ever functioned in Australia: but it was his ill luck

to be set to encounter, without the necessary temperament or experience, some of the most tempestuous crises known in our history. (C.B., 1858.)

Laughing Jackass. See KINGFISHERS AND BEE-EATERS.

Launceston, the second city of Tasmania, is situated in 41° 25′ S. lat. and 147° 10′ E. long., about 42 miles from the sea, at the confluence of the North and South Esk rivers—which, united, form the Tamar. The site was discovered on 9 January 1804 by William Collins, who was sent from Port Phillip by David Collins (q.v.) to explore the Tamar River; it was more carefully examined in the following December by William Paterson (q.v.) who had provisionally established his settlement lower down the river near Yorkton (see TASMANIA). In November 1805, after a failure of the crops at Yorkton due to the poor quality of the soil, Paterson recommended that farmers should be granted land on the upper Tamar, and that the tract of good ground at the confluence of the North and South Esks should be reserved for official purposes. Governor King having approved the suggestion and named the proposed site Patersonia, part of the establishment was located there in March 1806. By the beginning of 1807 the name Patersonia had been discarded for Launceston, after Launceston in Cornwall, England, where King was born, the northern half of Tasmania being already known as the county of Cornwall. Paterson had not yet fixed definitely on a headquarters for the Port Dalrymple settlement. Launceston was the centre of the agricultural district, but the need for a trading-port in the estuary of the river was recognized; Yorkton was not well suited for this purpose, but there were other sites available. On 27 September 1807 Governor Bligh gave instructions that the permanent headquarters must be selected before anything else was done. If, as he thought preferable, a site were chosen where shipping could discharge, Launceston would be regarded as an 'outpost' in the agricultural district. It was decided, however, to move the whole establishment permanently to Launceston; by 1810 Yorkton was abandoned, and no other site was selected for an estuary-port. In 1810 Oxley wrote that no better headquarters than Launceston could have been fixed on, in view of the beautiful country surrounding it and its accessibility to vessels drawing not more than 12 feet of water. Nevertheless in November 1811 Governor Macquarie, during his official visit to Tasmania, formed the opinion that it had many disadvantages. The township was situated in a low marshy flat, surrounded by high hills; the river being tidal, there was no fresh water in the vicinity, and the inhabitants were obliged to bring it down in boats. They suffered also from high prices, which were due in the main to difficulties of navigation. Moreover, ships passing through Bass Strait felt the want of a port on the coast, where they could effect repairs and obtain stores. Macquarie, after carefully considering the whole situation, decided to remove headquarters to the site in the estuary originally named Outer Cove by Paterson—who had established his first settlement there, but abandoned it in favour of Yorkton on the opposite bank when the water-supply threatened to fail. Macquarie, however, believed that Paterson's fear of a water-shortage was groundless, as abundance of it for every purpose could be obtained from a number of springs. The expense of removing the official establishment from Launceston to the new site (henceforth to be known as Georgetown) would not be great, as the few public buildings in Launceston were in 'a most ruinous decayed state' and of little value. Macquarie realized that Launceston would remain the agricultural centre of the Dalrymple settlement, but anticipated that Georgetown would become a large commercial centre and port. The change over was to be effected as soon as official sanction was received from the colonial office.

This was given in a despatch dated 3 February 1814. Further delay, however, was unavoidable, owing to the difficulty of obtaining enough government artificers and labourers to erect the necessary buildings at Georgetown; moreover, while Major Stewart was commandant (1815-18), there were continuous dissensions among the officials. In May 1819, the necessary buildings having been constructed, Georgetown became the headquarters of the settlement; only an officer and a small detachment were left at Launceston. But since the arrival in 1813 of the settlers from Norfolk Island (q.v.) there had been a marked agricultural development round Launceston, and the shifting of the commandant 40 miles from the centre of his command caused considerable inconvenience to farmers and townsfolk. Commissioner Bigge strongly condemned the change; on 2 October 1820 he pointed out to Macquarie that the land about Georgetown was proved to be of the worst description, and the cove too small to offer much protection to shipping; moreover up-river agriculturists objected to having their principal market 40 miles away. He recommended that the official establishment be moved back to Launceston. The buildings already erected at Georgetown could house a naval officer for the protection of trade and a small military detachment to prevent the escape of convicts. But Macquarie was adamant. As well might the settlers of Windsor and Parramatta complain that the metropolis of New South Wales should be at one or other of those townships, rather than at Sydney! A second visit to Tasmania in 1821 only served to strengthen his opinion of the superior advantages of Georgetown. Nevertheless, while awaiting the decision of the colonial office on Bigge's report, he suspended construction-work in Georgetown and ordered several public buildings to be erected at Launceston—a gaol, military barracks, a hospital, a commissariat store and granary, and accommodation for a military officer and an assistant surgeon. He also agreed to order the commandant to grant no more land in the town without his sanction, and to reserve the hill immediately above the town for official purposes. In March 1823 Lieutenant-governor Sorell, with the sanction of Governor Brisbane, moved most of the convicts from Georgetown to Launceston in anticipation of instructions from the colonial office to effect the change recommended by Bigge. Sorell also arranged for the erection of additional public buildings, including a church. On 31 July 1823 the anticipated instructions were despatched, and in the following year Launceston was officially reoccupied as the headquarters of the northern command.

In 1826 the township was surveyed and laid out. By 1827 it was a town of about 2000 inhabitants; extensive cargoes of wheat and wool were loaded at Reiby's wharf (see REIBY, THOMAS) by vessels of 250 tons burthen. No trade was carried on at Georgetown, which now contained only about 150 inhabitants, mostly

convicts. Thereafter the progress of Launceston was continuous. In 1825 George Howe had established *The Tasmanian and Port Dalrymple Advertiser;* in 1829 John Pascoe Fawkner issued *The Launceston Advertiser.* In 1828 the Cornwall Bank was established on the corner of Cameron and Wellington-streets; the Tamar Bank was opened in 1833; the Savings Bank in 1835 and the Bank of Australasia in 1836; in 1838 both the Union and Commercial Banks opened branches. In 1834 the chutes in the Cataract Gorge were erected by Andrew Sibbald to supply water to his mill—and, incidentally, to the inhabitants of the town, who had previously been dependent on supplies drawn from a considerable distance. Launceston whalers had stations at Portland Bay and Encounter Bay on the mainland. On 20 November 1835 Launceston became a free port.

During 1835 the town sent out two expeditions of great importance to Australia. On 10 May Batman dropped down the river in the *Rebecca* on his way to investigate Port Phillip; on 29 July Fawkner's party left the Tamar to search Western Port and, in the end, founded Melbourne.

Nor was the cultural development ignored during this period of growing prosperity. Though Launceston had no regular theatre until 1845 (see DRAMA), it had during the thirties a makeshift playhouse in which dramatic performances were given. In 1842 the mechanics' institute was opened, a Church grammar school was established in 1846, and a chamber of commerce—the first in Australia—in 1849. During the gold-rush many people from Launceston flocked across the strait to Victoria, but when the fever subsided the town settled down to steady development under civic administration. As headquarters of the northern settlement Launceston was under the control of a commandant until 1846, when that office was abolished. In October 1852 it was proclaimed a municipality (see LOCAL GOVERNMENT) and a system of local government was instituted. At the time the population numbered about 7300. In 1857 a marine board was formed for the development of the port; in the same year a water-supply scheme was approved, and a drainage scheme for the main streets was carried out. In 1858 a gas company was formed. In 1863 the South Esk suspension bridge was built. The Launceston and Western railway, the first sod of which had been turned by H.R.H. the Duke of Edinburgh in 1868, was opened in 1871, and in 1876 Launceston was connected by rail with Hobart. During the seventies there was a rapid development of the mining industry in the neighbouring districts; near the town the Waverley woollen mills, the Mount Bischoff tin-smelting works and the Cornwall pottery were established. A stock exchange was opened in 1881. When in 1888 Launceston was proclaimed a city, its population had increased to 17,000 with property the assessed value of which totalled £120,539. During the early nineties the city suffered from the financial collapse that led to the closing of the Van Diemen's Land Bank. Electric light was installed in 1895; in 1897 work was begun on the Victoria hospital for women, an infectious diseases hospital, the Victoria baths, and Victoria bridge. In 1898 the city council took over control of the Cliff Grounds in the Cataract Gorge. Since the completion of the Great Lake hydro-electric scheme (see HYDRO-ELECTRIC DEVELOPMENTS) cheap power has been available in the city for industrial undertakings. The population of Launceston at the census of 1921 was 24,319. See TASMANIA.

G.H.W.

Lauraceae, a large family of trees or shrubs abundant in tropical Asia and America, less plentiful in Africa; a few species occur in temperate countries. Seven genera with 50 species are indigenous to Australia. *Hernandia* is a small genus of trees with a wide range, chiefly tropical and maritime. *H. bivalvis* (Grease-nut Tree) is limited to Queensland, where the aborigines call it 'cudgerie;' on the Richmond and Clarence rivers this name is given by the local tribes to *Flindersia australis.* The shells of the fruit yield a dye soluble in soda but not in ether, alcohol, or water. The kernels contain an oil like common laurel oil, with the same stearine and narcotic odour. *Beilschmiedia obtusifolia,* found in eastern Australia, is a large handsome tree with aromatic bark, and yields a useful timber. See CASSYTHA, CINNAMOMUM, CRYPTOCARYA, ENDIANDRA, LITSEA.

Laurel, a name applied not only to members of the family Lauraceae (see CRYPTOCARYA), but to trees and shrubs of several other families, notably to species of *Pittosporum* and *Eupomatia.* For the Alexandrian laurel see GUTTIFERAE; the dodder laurel is a *Cassytha.*

Lavatera, a genus of the family Malvaceae, mainly European: one species, *L. plebeia* (Tree Mallow), is endemic in Australia. This is a coarse erect herb that becomes woody with age, whose flowers shade from rose-colour almost to white. Readily propagated from seed, it is frequently grown as an ornamental garden plant. In South Australia the roots of a white-flowered variety have been largely used by the natives for food; they are somewhat of the consistency of parsnips. The fibre has been used for rope- and paper-making, and, by the aborigines, for baskets and fishing-lines.

Lawes, WILLIAM GEORGE (1839-1907), born on 1 July 1839 at Aldermaston in Berkshire, was educated at the village school and trained for a business life at Reading, but in 1858 was accepted by the London Missionary Society for work in the South Seas, receiving his theological training at Bedford, and being ordained to the Congregational ministry on 8 November 1860. In 1861 he passed through Sydney on his way to Niue (Savage Island), where he landed in August. During 11 years of work there he completed a translation of the New Testament into the local language, and when he returned to England on furlough in 1872 took this with him, as well as translations of the Book of Exodus and the Psalms. In April 1874 he was appointed to the New Guinea mission, and settled at Port Moresby, where he worked for 21 years; he founded a training-school for natives, reduced the Motu language to writing, translated the New Testament, and, in conjunction with James Chalmers (q.v.) assisted the British authorities when a protectorate was proclaimed over New Guinea. On leaving Port Moresby Lawes went to Vatoraat, which he had made the headquarters of the training-school. In 1896 he visited Australia to see through the press several works in the Motu tongue, including selections from the Old Testament, 204 hymns, a catechism, a form of religious worship, an arithmetic, and a grammar and dictionary. Though less of an explorer than Chalmers, he was able in 1905 to mark on a map

96 villages with which he had established friendly relations. In 1906 he left New Guinea to reside in Sydney, where he died from pneumonia on 6 August 1907. Besides the text books and translations mentioned above he published in 1884 a brief account of explorations in New Guinea. His biography, by Joseph King, was published in London in 1909. J.C.

Lawn Tennis. The actual origin in England of lawn tennis is shrouded in mystery, but it is clear that the beginning of the modern game was the adaptation of royal tennis into an outdoor game by Major Wingfield about 1870. English visitors to Australia brought out implements, and played in different centres, but the actual introducer of the game will probably never be known. By the early eighties, however, it was played privately at all main centres of population, and the Sydney club was one of the first to give the game a definite footing. In Melbourne championships began in 1880, but not till 1885 was the first intercolonial match played. By this time there were two distinct schools of play—the Victorian, produced by playing on asphalt courts with the uncovered ball that rebounded high (often right above the head of the player), and the New South Wales school, produced by playing on grass courts with the covered ball that rebounded far less and was more solid. Victorians were forced by the high rebound to chop the ball downwards, and to reach the net as soon as possible in order to volley; New South Wales players relied far more on driving from the base-line, or from behind it. These two schools of play still largely affect the players of each State, and even to-day we have in J. O. Anderson of New South Wales the ultimate product of the highest skill in driving, while Norman Brookes and Gerald Patterson of Victoria have shown to how high a pitch of skill the volley can be carried. Still, in later years the players of each State adopted the methods of visiting champions from overseas—Wilding, Alexander, Beals Wright—till in Victoria there grew up fine drivers (R. W. Heath, Brookes himself—who is almost as good a driver as a volleyer—A. and P. O'Hara Wood, J. B. Hawkes, I. D. McInnes and R. E. Schlesinger), and in New South Wales fine volleyers like Dr. G. G. Sharp and A. H. Windeyer. But most New South Wales players still rely on their ground-strokes.

After 1885 the annual intercolonial matches between New South Wales and Victoria, played in Sydney and Melbourne alternately, produced many stirring contests, the best of which were the fights between Dudley Webb (one of the finest drivers and all-round players Australia ever produced) and 'Ben' Green, a volleyer at all risks, who led the Victorians into battle with strict orders that it was the net or nothing. Malcolm and the Chomleys, who taught Victorians the method of following the service to the net in doubles, laid the foundations, A. W. Dunlop with Norman Brookes sustained the high standard, and to-day Brookes, P. O'Hara Wood, Gerald Patterson and J. B. Hawkes carry on the great Victorian tradition, both in volleying and in doubles.

In New South Wales the best players of the early days were C. W. Cropper (who not only played the game but organized it as well), the brothers Fitzgerald, Dudley Webb (who was born in New South Wales, but played first as a resident of Victoria), Harold Fox and P. B. Colquhoun. In 1887 Lord Carrington, then governor, took a great interest in the game, and his private secretary Captain Wallington played in the intercolonial team. Webb first played for New South Wales in 1887, and Ben Green first for Victoria in 1889, and these two continued to represent their colonies till 1895. In the intercolonial matches Green generally had the best of it, but in the longer championship matches, finished a week later, Webb each year outlasted Green. Still, the contests were so close that on one occasion, Green having been seized with cramps, Webb came up to the net to wait, and was himself suddenly afflicted in like manner.

The first champion of New South Wales was Salmon, in 1885. Then Cropper won for two years, and Dudley Webb won five times in seven years, his run being interrupted by the successes of Dr. Colquhoun (of Victoria) and Dr. Eaves. Since then the list includes H. R. Crossman (three times), A. Curtis, A. D. Kearney (twice), H. Rice, Dr. Eaves again, Dr. Sharp (three times), R. W. Heath, H. A. Parker, A. Campbell, A. B. Jones (1912), A. O'Hara Wood (1913), J. O. Anderson (1914), and M. H. Marsh, who won the championship in 1915, and held it during the war. In 1919 it was won by J. O. Anderson, in 1920 by R. Neil, in 1921 by G. L. Patterson, in 1922 by R. V. Thomas, in 1923 by J. O. Anderson, and in 1924 by G. L. Patterson.

Championships began earlier in Victoria. The first champion was Highett in 1880, followed by Whyte, Keyser, Whyte again, Brind, W. Riddell (twice), A. G. Colquhoun (twice), Shuter, Cramond, Kearney (four times in all), Ben Green (three times), A. W. Dunlop (twice in all), T. C. Irving, H. Rice, Brookes (three times in succession), R. W. Heath, H. A. Parker, A. F. Wilding (twice in succession), S. N. Doust, Brookes again, J. C. Parke in 1912, R. W. Heath in 1913, A. O'Hara Wood in 1914, Gerald Patterson 1919-24.

In 1891 came Dr. Eaves, a visitor from the more advanced school of England, destined later on to revolutionize the game here. Having beaten all the best players in Victoria, including Green, he visited Sydney as a member of the Victorian team, and reached the challenge round of the championship with little opposition, but had hard work to dispose of Webb. His play taught Australians a good deal, and the Victorians profited most, for on his advice they discarded in 1891 the use of the uncovered ball. Up to this time the doubles game had been played on the original plan—one player close in at the net to snatch up every chance of killing with an interception and brilliant volley, and the other racing round the base-line retrieving the tosses and drives; but (whether it was the visit of Eaves, or just a spirit of invention, cannot be ascertained) just about this time, both in Sydney and Melbourne, was inaugurated the plan by which players followed their services to the net to volley the returns. In Victoria this plan was first adopted publicly by the brothers Chomley; in New South Wales it was adopted by the brothers Fitzgerald, suggested independently to the present writer by T. Kidston, and adopted with some doubts but good success. At first it was almost thought unfair, as tending to put the receiver off his stroke; but it was soon universally adopted, and has been adhered to ever since, both here and all over the world.

The battles between the driving of New South Wales and the volleying at all risks of the Victorians continued till 1902, with no great advance in skill. In 1902 Dr. Eaves paid Aus-

tralia a second visit, having by this time improved so that he was perhaps one of the greatest players then in the world; he had gone within one point of winning the American championship singles, and was just as close to the English championship singles. He defeated the best players here, including Norman Brookes, by this time the best player in Australia. With the true instincts of a sportsman, however, he taught Brookes the finer points of the game, including the famous American twist services, and showed him the higher value of delicate placing and volleying. Brookes had already ground-strokes of a high standard; he now added volleying that has never been exceeded in skill by any player in the world, and a well-worked-out scheme of knitting his strokes into one concerted game that left no loopholes for defeat; and in addition improved the American service immensely, so that his service became known as the Australian service.

Thus stood Australia in 1902. At the dinner given to the visiting teams in Sydney Harold Fox suggested that Australia should enter a team for the Davis Cup matches, instituted in 1900 as matches between England and America. The suggestion did not bear fruit until 1905, when Norman Brookes and A. W. Dunlop were both in England on a visit, and a young New Zealander, Anthony F. Wilding, was resident at Oxford. These three played for Australasia, and met a strong American team, going down after a good fight. Brookes that year was defeated by H. L. Doherty in the challenge round of the English championship, but showed clearly that his play was of the highest standard, and in a later match turned the tables on Doherty. Next year only Wilding and Dr. Poidevin were available, but in 1907 Brookes went to England again—largely at his own expense, for the gate-money in those days was small. This time Brookes and Wilding achieved success after great contests with America and England; the Davis Cup was brought to Australia, and was retained in 1908 against the assault of Beals Wright and F. B. Alexander, the American representatives. It was the contests in Melbourne between these two teams that first showed Victorians how great a game lawn tennis is. Next year two colts from America, M. E. McLoughlin and M. H. Long (both under 20 years of age), extended even Brookes and Wilding, and these matches taught New South Wales players as the previous year's had Victorians. As a result 'country week' was initiated by country players who had assembled in Sydney to see the Cup matches. To-day 'country week' is the greatest carnival in the world in perhaps any single sport, and is growing so fast that it will be difficult in future to provide a sufficient number of courts.

Since 1907 Australasia has held the Davis Cup for 12 years, and at present Australian players stand in singles only second to those of the United States; in doubles Australia stands just as clearly first, by better methods of play and position. This is the result of nearly 40 years of intercolonial and inter-State matches.

In *Queensland* there has been ever since 1895 a strong body of players. The best is C. B. St. John, who, though disabled from birth by the lack of a right hand, has conquered this defect, and is a fine all-round sportsman—including cricket and football—as well as the best lawn tennis player Queensland has ever produced. *Tasmania* has had one player of outstanding merit in J. McGough, who won the State championship 14 times in all. In *South Australia* the game has flourished for 20 years; R. V. Thomas and G. M. Hone are outstanding players. In *Western Australia* the play is not of so high a standard; but the late E. F. Parker (killed in action) was one of the best players Australia ever produced, though his development was hampered by remoteness from other good players. R. H. Gemmell, the present champion, ranks high. Among *Victorian* players Norman Brookes, of course, has stood out most, but the record of Gerald Patterson for the last five years equals or excels that of any predecessor, and to-day he has only one peer in Australia, J. O. Anderson.

In *New South Wales*, after the retirement of Dudley Webb and H. R. Crossman, Horace Rice came into prominence; he has played in 60 intercolonial and inter-State matches over a period of nearly 30 years, has won championships in every State of the Commonwealth, and has played for Australia in the Davis Cup contest. Dr. G. G. Sharp has the best record—three successive wins in the singles and three in the doubles—and at his best was close even to Brookes. A fine doubles player was G. W. Wright, who with Dr. Sharp won the doubles championship three times, and also won it later with A. B. Jones—whose partnership in 1913 with S. N. Doust, another Sydney player, showed them to be the best pair in the world after the Brookes-Wilding or Brookes-Dunlop pair. In 1922 Patterson and P. O'Hara Wood defeated the American Davis Cup pair, Brookes and Patterson did so in 1919, and J. O. Anderson and Hawkes nearly did so in 1923. In 1919 Thomas and O'Hara Wood won the world's championship, and in 1922 Anderson and Lycett did so; Lycett, by the by, who learnt his tennis from childhood in Australia, won the world's championship doubles three times in succession with different partners.

In every State save Victoria and Tasmania it is possible to play throughout the year on grass, but in country towns the game is usually played on hard courts. The chief difficulty for the last five years has been to provide enough courts. An arena with nearly 50 courts has been constructed near Sydney—thanks to M. H. Marsh, F. D. McMaster and others—at a cost, when the grand-stands have been constructed, of nearly £70,000; a similar ground of less size has—thanks to Mr. Justice Weigall, N. E. Brookes and others—been provided at Kooyong near Melbourne; another area has been provided in Adelaide, and in Brisbane—thanks to R. D. Frew—there is also a large ground with many courts. In Perth there are many fine grass courts. The municipalities of Sydney and Melbourne are providing on the public parks many courts, which are to be let at a small fee; this example is being followed in the other State capitals and by many suburban municipalities. Games are now played on hard courts at night with electric lighting.

In each State the game is controlled by an association to which clubs are affiliated. Over all is the Australasian Association, which controls the Australian arrangements for Davis Cup matches, the relations between the State associations, and the Australasian championships, and sanctions championships.

The game has in Australia such a hold now that the sway of cricket is seriously threatened. An enthusiast in the north of Queensland travels on his aeroplane 60 miles on Sunday morning to the nearest sheep-station, plays all day and 'planes back at night. The Lawn Tennis Association of Victoria had by the end of December 1923 sanctioned 20 tournaments between Christ-

mas and Easter, and in Sydney the entries for 'country week' totalled 98 teams of men and women (usually six in a team) coming from towns, stations, and selections. Championship contests run from early January till late December; in Sydney inter-club matches have sometimes been played on grass each Saturday for two winters in succession, without one interruption by rain. This development here of a single sport in 40 years results from the genius, or the generosity, of three men—Dwight F. Davis of the United States, who gave the famous cup; Norman Brookes of Victoria; and Anthony F. Wilding of New Zealand. The prowess of Brookes and Wilding in 1908 brought the Davis Cup to Australia, and retained it there, with the assistance of lesser players, until 1919 (but for a short interval in 1913). The contests in Australia and New Zealand for the Davis Cup showed Australians what the game really was, and gave them the desire to excel in it. Credit must also be given to another Australian, Dr. W. V. Eaves, who, having learned all his game in England, came here in 1891 and 1892, defeated all opponents, and taught Norman Brookes the higher points of the game. R.M.K.

Lawry, WALTER (1793-1859), born at Bodmin in Cornwall in 1793, was received into the Methodist ministry at the conference of 1817 and appointed to the Australian mission as assistant to Samuel Leigh (q.v.). He arrived in Sydney on 2 May 1818, and worked with Leigh until 1820 when, the mission having been divided into three circuits, he was given charge of Parramatta. His project for the erection of a chapel there met with some opposition, as some subscribers wished it to be a purely Methodist chapel, whereas others wished to throw it open to any nonconformist minister; consequently he built it in the end largely at his own expense, on a site given him by Governor Macquarie. Meanwhile he had interested himself in missionary work in Tonga, and in 1820 his offer to go to the Friendly Islands was accepted by the committee in London. On 16 August 1822 he reached Tonga with a small party, to be at first welcomed by the natives; but their friendliness was soon replaced by suspicion and distrust, and, after facing many hardships, he re-embarked for New South Wales on 3 October 1823. Returning thence to England, he did circuit work there until 1843, when he was appointed general superintendent of missions in New Zealand and Polynesia. This position he held for 11 years, and then returned to Sydney. He died at Parramatta on 30 March 1859. His *Friendly and Fiji Islands* is valuable for its information on early mission effort in the South Seas.

Lawson, HENRY ARCHIBALD (1867-1922), born at the Weddin Mountain diggings near Grenfell in New South Wales on 17 June 1867, was the son of Peter Hertzberg Larsen—a Norwegian who came to Australia as quartermaster of a Norwegian vessel and, like so many sailors of the time, left his ship to seek fortune on the diggings—and his wife Louisa Albury, of whom an account is given below. After a youth spent in the bush near Mudgee Henry came to Sydney in 1883 and earned his living as a house- and coach-painter, a trade in which employment was often very irregular. In 1887 he was working in Melbourne, in 1889-90 in Western Australia (at Albany), and during intervals he took up-country jobs. At the same time he was experimenting with journalism; he helped his mother with her *Republican* and *Dawn,* and in October 1887 saw his 'Song of the Republic' published in the Sydney *Bulletin,* which thereafter took most of his verses and stories. In 1891 he secured a position on the short-lived Brisbane *Boomerang*; when it failed, he came back to Sydney, and in 1892 undertook for the *Bulletin* a tramp (with spells of work on stations) from Bourke to Hungerford and back. From this trip and his youthful memories Lawson gained his intimate insight into bush life and the qualities and emotions of residents 'out back.'

In 1893 he for a short time edited the *Worker*; the next year he spent in New Zealand; then he was given a post in the office of the New South Wales government statistician—it seems a habit of Australian governments to encourage literature by giving the writer a routine clerkship. In 1894 his first book—*Short Stories in Prose and Verse*—had been published from the *Dawn* office; in 1896 appeared two important volumes, verse in *In the Days When the World was Wide,* prose in *While the Billy Boils*—the latter containing what is probably his best prose work. More travel followed, first to Western Australia, then to New Zealand (where he taught young Maoris in a bush school), then—in 1900-2—to London. After his return to Australia he lived nomadically and wrote profusely, on rare occasions equalling or passing his earlier standard; in a selected edition of his verse published in 1918 70 per cent of the contents date from 1900 or earlier. He never succeeded in sustained efforts; the poems by which he will be remembered—e.g. 'The Sliprails and the Spur'—are short lyrics of highly concentrated emotion; and his best work, which has attained a reputation in Europe, is found in his pre-1900 prose stories. Apart, however, from purely literary considerations, his work gained (and will retain) wide popularity in Australia because of its peculiarly Australian quality. No other writer has so continuously and clearly reflected the souls of his own folk; as David McKee Wright says truly, 'there is not a word in all his work which is not instantly recognized by his readers as honest Australian . . . . he is the first articulate voice of the real Australia.' He died on 2 September 1922. It is understood that his second name 'Archibald' was given him by mistake, the rather deaf minister who christened him having misheard the father's 'Hertzberg.' See LITERATURE.

Lawson's published works (with the dates of their first editions) are *Short Stories in Prose and Verse* (Sydney, 1894); *In the Days When the World Was Wide* (Sydney, 1896); *While the Billy Boils* (Sydney, 1896); *On the Track and Over the Sliprails* (Sydney, 1900); *Verses, Popular and Humorous* (Sydney, 1900); *Joe Wilson and His Mates* (London, 1902); *Children of the Bush* (London, 1902); *When I Was King* (Sydney, 1905); *The Rising of the Court* (Sydney, 1910); *The Skyline Riders* (Sydney, 1910); *For Australia* (Melbourne, 1913); *Triangles of Life* (Melbourne, 1913); *My Army, O My Army* (Sydney, 1915). A volume of *Selected Poems,* containing his best work in verse, was published in Sydney in 1918, and a definitive edition of his verse in three volumes in 1925.

Lawson, LOUISA (1848-1920), born at Guntawang near Mudgee in 1848, was the second child of Henry Albury, a Kentishman with gypsy blood in his veins who was successively shearer, carter and timber-getter in the Mudgee district. At the age of 18 she married Peter

Larsen, and they moved to Grenfell in the hope of winning gold on the diggings there, after a year returning to Eurunderee in the Mudgee district and settling there on a selection. The poverty of the land and the droughts of the early eighties drove the family to Sydney, while Peter Lawson (as he was by then called) found work near Rylstone and afterwards near Hartley. Louisa Lawson, after a short venture in boarding-house-keeping, determined to devote herself to journalism. In 1887 she bought a journal named *The Republican* and trained her son Henry to edit it, but in the following year embarked on a new venture—*The Dawn*—a journal edited, printed and published by women, in which for 17 years (May 1888 to July 1905) she upheld the feminist cause. In 1905 she published at the *Dawn* office *The Lonely Crossing and Other Poems* (2nd edition, 1909). It was through her zeal that the insignificant wooden cross at first placed on the grave of Henry Kendall in Waverley cemetery was replaced by a monument more worthy of him. In 1898 she founded the journal *Young Australia*. She died at Sydney on 12 August 1920.

Lawson, WILLIAM (1774-1850), born on 2 June 1774 at Finchley near London, on 20 June 1799 joined the New South Wales Corps as ensign, and in 1800 reached Sydney with a detachment of the corps and was sent to serve on Norfolk Island, where he ran a small flock of sheep. By 1806 he was back in Sydney, and on 14 November was promoted lieutenant; he sat on the court martial that tried D'Arcy Wentworth (q.v.) in 1807, and the criminal court that Bligh assembled to try John Macarthur in January 1808, became Johnston's aide-de-camp after the mutiny, and at the end of the year was appointed commandant at Newcastle. Here he came into collision with Henry Browne Hayes (q.v.), who sided with Bligh, had been exiled to Newcastle therefor, and was issuing pasquinades against the provisional government. When Macquarie arrived, Lawson was sent to England with the corps and summoned to attend the trial of Johnston, who regarded him as an important witness; but in April 1811, before the trial came on, he and two other officers of the corps managed to secure a passage back to New South Wales in the *Admiral Gambier*, and obtained appointments in Macquarie's new 'veteran corps' formed out of New South Wales Corps men who wished to settle in the colony. It would seem that Lawson—whose principal interest from the first was farming—had followed Johnston in the mutiny purely as a matter of discipline, and was not considered by the authorities to have been influenced by those personal motives that undoubtedly swayed Macarthur and others.

Lawson now retired to Veteran Hall, on his property at Prospect, but in 1813 joined Gregory Blaxland in his successful attempt to find a way across the Blue Mountains (see EXPLORATION BY LAND). In this journey Lawson was the surveying expert, and his journal (preserved in the Mitchell Library at Sydney) records times and distances with such minute detail that the explorers' course can be laid down hour by hour on a map. For his services he received a grant of 1000 acres, which he located on Campbell's River near Bathurst; and in August 1819 Macquarie made him commandant of the settlement there, describing him later as 'a most meritorious and useful officer.' During his tenure of this office he devoted a great deal of time to exploration, and in at least three journeys in 1821-2 opened up the district of Mudgee, and a track from Bathurst northwards to Mudgee and right through to the Goulburn River. In the Mudgee district he gradually accumulated large properties, extending to the Talbragar River. Brisbane in 1825 described him as 'one of the most extensive Land and Stock owners in the colony . . . . a reasonable and not illiberal man.' In 1824 he resigned his post at Bathurst and retired to Prospect, where he spent the rest of his life, dying there on 16 June 1850. The discovery of the Mudgee district has often been attributed to him: but he himself gave the credit for it to James Blackman, chief constable at Bathurst, on whose information both Lawson and the Cox brothers hastily opened up the district and secured the best of the land.

It has usually been assumed that Gregory Blaxland was the originator and leader of the expedition that first crossed the Blue Mountains, and the weight of evidence still favours that assumption; but notice must be taken of a claim, put forward in 1827, that Lawson devised the method of penetrating the tableland by keeping along its highest points. The anonymous author of 'A Ride to Bathurst' in the issue of *The Australian* for 13 March 1827 asserts that Lawson frequently discussed the problem with his unsuccessful precursor George Caley; in the end he made up his mind to attempt a crossing along the summit-levels, foreseeing 'that the timber and scrubby underwood would there be thinnest, and that a long continuous flat or table land would offer much smaller impediments' than the previously tried routes up the valleys. So, the anonymous author continues, Lawson 'secured an agreeable companion in Mr. William Wentworth, and a persevering assistant in Mr. Gregory Blaxland,' and achieved the passage. Although several other assertions in the 'Ride to Bathurst' were promptly challenged, this was not. But Gregory Blaxland had left for England a month earlier, and it was no one's business to interfere on his behalf. Lawson, who was living at Prospect Hill, did not trouble to disclaim the assertion.

Blaxland himself states positively that he devised the plan, was asked by Macquarie to carry it out, and invited Lawson and Wentworth to join him (see his letter to John Oxley Parker which prefaces the *Journal of a Tour of Discovery*). The *Sydney Gazette* of May 1813 mentions Lawson first in its paragraph relating to the expedition: on the other hand, Macquarie in his general order and despatch invariably mentions Lawson last of the three. Until further evidence comes to light the anonymous assertion of 1827 cannot outweigh Blaxland's of 1823; but its fulness of detail entitles it to consideration.

Lawyer Vines. See LILIACEAE.

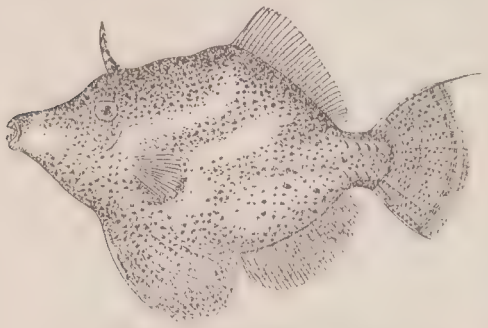
Leaf-insects. See STICK-INSECTS AND LEAF-INSECTS.

Leather-head. See FRIAR-BIRDS.

Leather Jacket. See RHAMNACEAE.

Leather-jackets, members of the family Monacanthidae which occur in all temperate and tropical seas, but are more plentiful in Australia than elsewhere. As is indicated by their vernacular name, they are protected by a tough skin beset with countless minute prickles. A strong spine above the head can be erected, and locked in position by bony structures at its base,

thus becoming a valuable protection against larger enemies that might wish to swallow the fish. Leather-jackets are well known to fishermen on account of their habit of nipping lines through with their sharp teeth; these are remarkably compressed, and so disposed towards one another as to form beak-like structures in the jaws. Their colours are often of great beauty; when the fish are first captured, lines



Fan-bellied Leather-jacket (*Monacanthus chinensis*).

and spots of opalescent green and blue scintillate during their convulsive death-throes, but disappear within a few minutes. Leather-jackets are good eating after the tough skin has been removed. They are often attacked by a large crustacean parasite, which bores under the skin, and eats away the living flesh.

The Monacanthidae and allied families are peculiar among fishes in their use of the dorsal and anal fins. In most fishes these serve merely for balancing, the tail alone being used for propulsion. But in the leather-jackets an undulating, wave-like motion of the dorsal and anal fins serves to move the fish forward, and the tail, in leisurely movement, serves only as a rudder.

A. R. McC.

Leeches, vernacular name of the Hirudinea, a class of worm-like animals usually classed among the chaetopods or bristle-worms (q.v.), widely distributed in all parts of the world, and frequenting both fresh and salt water as well as the land. Of land and freshwater leeches several interesting species are found in Australia; of the former there are two genera, *Philaemon* and *Geobdella*—the first represented by *P. pungens*, which is peculiar to Australia and Tasmania; of the second *G. australiensis* and *G. Whitmani* are Australian and *G. tristriata* is found in New Guinea. They are voracious creatures, lurking among dead leaves and under logs, and eagerly attacking man and other animals. *P. pungens*, however, roams freely about in the scrub, attaching itself adroitly to the ankles of unwary wayfarers, where it gorges itself with blood before dropping off. Its egg-capsules are light-brown spherical objects about one-third of an inch in diameter, whose surface is covered with a peculiar honeycomb-like projecting netting; they are commonly found under logs.

Among freshwater leeches two genera, *Dineta* and *Semilageneta*, are not found elsewhere; the cosmopolitan genera *Glossiphonia* and *Hyperobdella* also occur. The largest of our species, *Limnobdella australis*, is used for medicinal purposes.

See *Proceedings* of the Linnean Society of New South Wales, 1909-1910. T.S.

Leeper, Alexander, born at Dublin on 3 June 1848 and educated at Trinity College, Dublin (B.A., 1871; M.A., 1875; LL.D., 1884) and St. John's College, Oxford (1st class in classics, 1874), in 1875 migrated to Melbourne and in the following year was made warden of Trinity College within the local university. Elected in 1880 to the university council, he resigned in 1887, but was re-elected in 1900. Under his direction were produced the first Latin (*Mostellaria*) and the first Greek play (*Alcestis*) ever staged in Victoria, and in 1896 he staged *Strafford*, the only play by Robert Browning that has been produced outside the mother-country and the United States. His services to classical study in Australia have been great, and he was the founder and first president of the Victorian Classical Association. In 1918 he resigned his wardenship and retired into private life, diversified with a lay canonry of the Anglican cathedral and the chairmanship of trustees of the public library.

Lee Steere, Sir James George (1830-1903), born in 1830 in Surrey, England, was 3rd son of Lee Steere, once member for that county. Migrating to Western Australia in 1860, he became a pastoralist, and in 1868 a nominee member (unofficial) of the old legislative council, of which he was speaker from 1886 to its dissolution in 1890. In that year he was elected to the new legislative assembly, and became its speaker—an office which he held till his death. He took great interest in federation, representing his colony on the federal council in 1886-8-9, and attending as delegate the conference of 1890 and the convention of 1891. He died on 1 December 1903. (Kt. Bach., 1888; K.C.M.G., 1900.)

Lefroy, Sir John Henry (1817-1890), born in Hampshire on 28 January 1817, passed into the royal military academy at Woolwich in 1831 and in 1834 was gazetted second lieutenant in the artillery (lieutenant, 1837; captain, 1845; lieutenant-colonel, 1855; brevet-colonel, 1858; brigadier-general, 1864; major-general, 1868; lieutenant-general, 1877; general, 1882). His military activities were great and useful. He was the first secretary of the royal artillery institution, compiled a handbook of field artillery that was much used during the Crimean war, became scientific adviser to the war minister in the same war (being the first to recommend the use of rifled ordnance), and gained the friendship of Florence Nightingale during a mission to Constantinople; after the war he reorganized the staff college at Sandhurst, initiated the school of gunnery at Shoeburyness, reported on the British fortresses in the Mediterranean, worked on the ordnance select committee (secretary, 1860; president, 1864), and in 1868 was appointed director-general of ordnance. Resigning in 1870, he was next year made governor of the Bermudas (1871-7), and subsequently acted for a year as governor of Tasmania (1880-1). Throughout his life he was keenly interested in magnetic science, and from 1839 to 1853 was entrusted with special observational work of this kind, first at St. Helena (1840-2), and afterwards at Toronto in Canada. His observations during an expedition into north-western Canada (1843-4) 'remain the chief authority for the determination of the approximate position of the forces of magnetic intensity in North America' (*D.N.B.* xi. 841). While in Tasmania he returned to this subject with

a paper read before the local Royal Society, 'On the Magnetic Variation at Hobart.' Returning to England in 1882, he died in Cornwall on 11 April 1890. (C.B., 1870; K.C.M.G., 1877.)

Leguminosae, a very large and widespread family of plants. In number of species it is the second among flowering plants in the world; among those of Australia it is first, being represented by 1276 species of great variety of form and very widely distributed. The family, whose salient character is the seed-pod or legume, is divided into three main groups:
(I) Papilionaceae, or butterfly flowers (e.g. the Darling pea, Sturt's desert pea and the garden bean), containing the majority of pea-flowered genera;
(II) Caesalpineae, having irregular flowers with spreading petals (e.g. the cassias);
(III) Mimoseae, having numerous small flowers combined in a head or spike (e.g. the acacias).

Sphaerolobium is a genus endemic in Australia (and chiefly confined to Western Australia) of small shrubs with rush-like stems, frequently leafless. *S. vimineum* grows in tangled masses, usually in swampy stations; the interlaced wiry stems carry on their tips numerous clusters of small flowers. The small pods (about 2 lines in diameter) are nearly globular. *Daviesia,* also endemic, has small yellow, orange, or red flowers, flattened triangular pods and rigid, more or less spiny leaves. Other endemic genera are *Pultenaea, Goodia* and *Barklya.*

Pultenaea is a large genus of shrubs with opposite or whorled leaves, flowers usually yellow, frequently marked with purple, collected into leafy heads; *P. daphnoides* and *P. flexilis* are ornamental shrubs, easily grown from seeds. *Goodia* comprises shrubs with leaves divided into 3 leaflets (as in trefoil), and large yellow flowers with a purple base; *G. lotifolia,* occasionally called clover-tree, is reputed to be poisonous to stock. *Barklya* consists of a single species, *B. syringifolia,* a handsome tree, largely grown as an ornamental garden-plant. Its leaves are simple, broadly heart-shaped; flowers small, bright golden yellow, in dense narrow spikes; pod flat, the valves thin. It has a close-grained timber of a blackish-grey colour.

Peltophorum is a small tropical genus of tall trees with yellow flowers; the Australian species, *P. ferrugineum,* has a blackish timber much in request for cabinet work.

See Acacia, Albizzia, Bauhinia, Bossiaea, Canavalia, Caesalpinia, Cassia, Castanospermum, Clianthus, Crotalaria, Derris, Dillwynia, Erythrina, Gastrolobium, Gompholobium, Hovea, Indigofera, Jacksonia, Kennedya, Lotus, Mirbelia, Mucuna, Oxylobium, Psoralea, Sesbania, Sophora, Tephrosia, Trigonella, Vigna, Viminaria.

Le Hunte, Sir George Ruthven, was born in Wexford county, Ireland, on 20 August 1852, educated at Eton and at Trinity College, Cambridge (B.A., 1873; M.A., 1880), and admitted a barrister of the Inner Temple in 1881. He was for some time private secretary to Sir Arthur Gordon, the first governor of Fiji, and in 1875-87 served in various offices in that colony; in 1883 he was judicial commissioner on the high commission for the western Pacific. In 1887 he was transferred to the West Indies to be president of Dominica; from 1894 to 1897 he was colonial secretary of Barbados, and for a short time in 1897 was colonial secretary of the Mauritius. In 1898 he was chosen to succeed Sir W. MacGregor as lieutenant-governor of British New Guinea, and for five years administered the protectorate with a genial impulsiveness that sometimes troubled his subordinates greatly. On 1 July 1903 he was transferred to the governorship of South Australia, and left Australia at the end of 1908 to take up the governorship of Trinidad and Tobago—a position in which his administrative talents and knowledge of tropical conditions had more play than at Adelaide. He retired from the public service at the beginning of 1916. (C.M.G., 1898; K.C.M.G., 1903; G.C.M.G., 1912.)

Leichhardt, Friedrich Wilhelm Ludwig (1813-1848), was born at Trebatsch (a village 45 miles SE. of Berlin) on 23 October 1813, studied at Gottingen and Berlin, and with William Nicholson of Clifton travelled in France, Italy, and England. Having evaded military service and been proclaimed a deserter, he migrated in 1841 to New South Wales, and for two years investigated the petrology and botany of the Moreton Bay district, forwarding numerous fossils to Professor Owen in England. The results of his labours appeared in several German scientific periodicals and in Owen's reports to the British Association in 1844. An expedition to explore the northern parts of Australia having been projected, Leichhardt applied for the position of naturalist; but the delays disappointed him, and by means of private contributions and his own resources he succeeded in equipping an expedition, the story of which (and of his later explorations) is told under Exploration by Land.

The most remarkable feature of his first expedition was that it reached any destination at all. Ernest Favenc, himself an explorer, describes Leichhardt as 'a man whose character, to judge from his short career, was largely comprised of contradictions and inconsistencies. Eager for personal distinction, with high and noble aims, he yet lacked that sympathy and feeling of comradeship that attracts men. Leichhardt's followers never desired to accompany him on a second expedition . . . . The journal of the trip reads to a man accustomed to bush life like the tale of the Babes in the Wood, yet he managed to blunder through.' On his last expedition, however (that of 1848), his luck failed him, perhaps because his companions were less experienced bushmen than usual. He wrote cheerfully on 4 April from a camp on the Cogoon River Muckadilla Creek), and then vanished into the unknown western region. No authentic trace of him has ever been discovered; but endeavours to find him were responsible for A. C. Gregory's explorations of 1855-6. Before he died the King of Prussia had pardoned him, at the request of Alexander von Humboldt, for desertion, and given him permission to return to Prussia; but it is uncertain whether the pardon ever reached its destination.

Leichhardt's Tree. See Morinda.

Leigh, Samuel (1785-1852), born of Anglican parentage at Milton in Staffordshire on 1 September 1785, while still young attended Methodist cottage services, and after a time joined the Independent congregation at Hanley. Responding to a call for workers on the mission-field, he commenced the study of theology under Dr. Bogue of Gosport, one of

the founders of the London Missionary Society, with whom he agreed to remain for three years. At the end of the first year, however, he left; Bogue was a Calvinist, and Leigh an Arminian, and their theology would not harmonize. Joining the Methodist Society at Portsmouth as assistant to Joseph Sutcliffe, Leigh met Dr. Coke, the great missionary, then on his way to Ceylon. After labouring at Shaftesbury for two years, he was accepted by the Methodist conference of 1814 for mission work, and nominated to North America; but the Canadian Methodists thought it wiser in that disturbed year to do without a missionary, and Leigh was transferred to New South Wales. When on 3 October he had received ordination from the hands of Dr. Adam Clarke and others (having already on 30 September taken the necessary oaths before the Lord Mayor of London), Lord Sidmouth sanctioned his departure for New South Wales, but (curiously enough) does not seem to have consulted Lord Bathurst, the secretary for the colonies; consequently, when Leigh reached Port Jackson, Macquarie felt bound to report to Bathurst that he had arrived 'without any letter or pass from your lordship's office,' and went on to recommend 'that no persons of his description should in future be permitted to come out.' He had no personal objection to Leigh, but did not want 'sectaries' in a new and rising colony. Bathurst sympathized, and, while authorizing Leigh's residence in the colony 'so long as he shall continue to conduct himself with propriety and decorum,' promised to use great caution in sanctioning the admission of other 'sectaries.'

Leigh sailed in the *Hebe* on 28 February 1815, at the cost and under the direction of the Wesleyan Missionary Society, to which he held himself entirely responsible. On arrival in Sydney (11 August) he waited on Macquarie and on the government chaplains—Marsden, Cowper, and Cartwright. Macquarie was not inimical: Leigh, he reported seven months later had 'conducted himself very quietly and inoffensively;' his personal regard for Leigh grew steadily, and his support was constant and valuable. The chaplains, for their part, received him readily and helped him consistently. He held his first service in a house in the Rocks quarter of Sydney, and went on to organize Methodism in Sydney, Castlereagh, Parramatta, Liverpool, and the settlements on the Hawkesbury (where he preached in a wooden skillion); he also at Macquarie's request visited Newcastle. Not long after his arrival in Sydney he founded a Benevolent Society which, Macquarie having given it a building, became 'The Sydney Asylum for the Poor' and in 1818 the Benevolent Asylum; this was one of the earliest examples of joint effort among the denominations, William Cowper and Robert Cartwright (both Anglican chaplains) joining Leigh in the establishment of the asylum, and Bathurst refusing in spite of strong pressure to make it a denominational institution. In 1818 Leigh, whose health had suffered greatly from privations, persuaded the missionary society to send out William Lawry (q.v.) to his help; he then visited New Zealand (where he stayed nine months), went back to England in 1820, and on his return to Australia in 1821 established a mission at Hobart. In February 1822, at Marsden's suggestion, he went again to New Zealand, where he founded the Wesleyan mission at Whangaroa. Leaving New Zealand in September 1823 in the *Brompton*, he was wrecked on a lonely island and suffered great privation for three days. He again took up work in Parramatta, but not for long; then, returning to England, he continued in circuit work till 1845, when he retired to Reading. While advocating the interests of the Australian mission, he was seized with paralysis, from which he died on 2 May 1852, at the age of 66.

Though not possessing great intellectual power, Leigh was a true missionary, with the earnestness of an apostle. He opened at Castlereagh the first Methodist chapel in Australia; he assisted at the opening ceremonies of Princes-street and Macquarie-street chapels; he rendered valuable help in the formation of a branch Missionary Society, a Tract Society, and a Bible Society. The theological college at Enfield and the Macquarie-street church at Parramatta are named in his honour.

Strachan's *Remarkable Incidents in the Life of the Revd. Samuel Leigh*, published in London in 1855, is the principal authority for Leigh's doings. An account of his New Zealand mission will be found in Buller's *Forty Years in New Zealand*.

Lemons. See FRUIT-GROWING.

Lennox, DAVID (1788-1873), born at Ayr in Scotland in 1788 and trained as a stonemason, was employed until he was 44 on various bridge-building jobs in England, including the masonry of the famous Menai bridge, some of the London bridges, and the construction of a large number of wooden bridges for the government across the Gloucester-Berkeley canal. He was also foreman builder on the stone bridge at Gloucester, of 150-feet span, which Telford had adapted from one of the arches of a remarkable bridge by Perronet over the Seine at Neuilly in France. The unusual design of the Gloucester bridge stuck in Lennox's mind, and several of his best works in Australia are patterned on it.

In 1832 he migrated to Sydney, which he reached on 11 August, and at once took employment as a stonemason on government work. Here almost immediately Major Mitchell, surveyor-general, then much exercised over the poor condition of most bridges in the colony (they were nearly all wooden, and many had been damaged by fire or flood), found him and engaged him as bridge-engineer. (It is probable that Lennox had sent in his testimonials to Mitchell already, but had not awaited a reply before finding work.) Mitchell was enthusiastic about him, and Bourke, with whom the appointment lay, on 1 October made him sub-inspector of roads and superintendent of bridges, with apologies to the colonial office for having appointed a 'practical' man instead of an assistant-surveyor of the type previously supplied from England. Lord Stanley, however, the then secretary of state for the colonies, approved highly of the change; and 'thus,' said Mitchell 23 years later, 'originated all the bridges this colony possesses worthy of the name.' Among them should be noted the Lapstone bridge on the first slope of the Blue Mountains (1833), with a semi-circular arch; the Lansdowne bridge over Prospect Creek on the main southern road, opened in 1836—built on the Neuilly pattern, with a span of 110 feet; the Lennox bridge at Parramatta, an 80-feet span, also of the Neuilly type, completed in 1839; and several smaller stone and wooden bridges over creeks intersecting the main roads to Goulburn and Bathurst. In 1837 Mitchell's department of roads was transferred to the care of a detachment of royal engineers, and Lennox seems to have been at a loose end for some years; in 1839-41 he was building St.

Andrew's Presbyterian church at Parramatta, and in 1843 was made district surveyor to the Parramatta district council. But in 1844 Gipps appointed him superintendent of bridges at Port Phillip for the special purpose of bridging the Yarra, and in 1845 he was entrusted with the construction of a bridge of 150-feet span, again of the Neuilly type, which on 15 November 1850 was formally opened and named 'Prince's Bridge.' The three New South Wales bridges already mentioned are still in use, but Lennox's Yarra bridge had to be demolished in 1884, when the river channel was considerably widened. During his term of duty in Victoria, which lasted till November 1853, Lennox not only designed and built more than 50 bridges, but was in charge of all the construction of roads, wharves and jetties in the Port Phillip district. Having worked all his life on an inadequate salary (Bourke gave him £120 a year, and afterwards £200; Gipps gave him £250, and the Victorian government when it came into existence made the salary £300), he had no savings to retire on, and was granted by the Victorian council £3000—the first adequate acknowledgment of his services. He returned in 1855 to Parramatta, and lived there quietly until his death on 12 November 1873.

The only trustworthy account of Lennox's life, written by Henry Selkirk, was published in vol. vi, part v, of the Royal Australian Historical Society's *Journal*, and from it this account has been summarized.

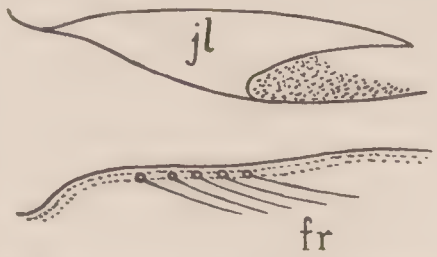
Leopard Tree. See FLINDERSIA.

Lepidoptera, a very large order of insects, abundantly represented in Australia; about 7900 species have already been described, of which 334 are butterflies, the rest moths. Many hundreds of new species still await description. All illustrations referred to in the text will be found on plate ix.

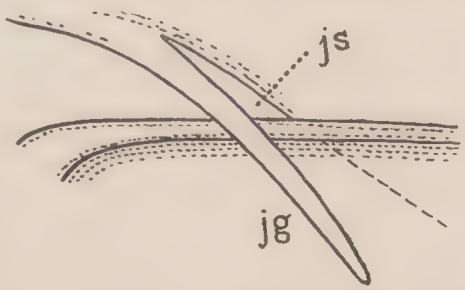
The order as a whole is characterized by the presence upon the wings of scales (modified hairs), in which are deposited the pigments that give the wings their brilliant colours and intricate patterns. The wing-venation is characterized by the elimination, in all but the lowest forms, of the main stem of the media, leaving the wide basal cell as a clear area between the radius and cubitus. The mouth-parts, originally of the mandibulate type still preserved in the lacewings and their allies, have become secondarily evolved to a sucking (haustellate) type, the galeae of the two maxillae becoming elongated to form a sucking-tube; this in some of the higher forms, such as the hawk-moths, becomes immensely long and is carried rolled up in a closed spiral. The larva is a caterpillar, normally with three pairs of thoracic legs and five pairs of abdominal prolegs (claspers), inclusive of the anal pair. The pupa, often called a chrysalis, is usually of the type known as a *pupa obtecta*, but in some cases is a *pupa incompleta*, with greater capacity to move its segments freely. It is often enclosed in a silken cocoon.

The subdivision of the order into butterflies (Rhopalocera) and moths (Heterocera) has long ago been discarded by men of science. In this article a more natural subdivision will be adopted.

In the sub-order Homoneura the venation of the fore and hind wings is similar, each wing having 12 veins ending on the margin, exclusive of the anals. The wings are coupled together loosely in flight, the fore-wing possessing either a fibula or jugal lobe (Micropterygidae)



Jugal lobe and frenulum in Micropterygidae.

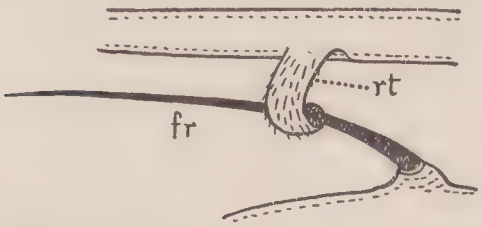


Jugum in Hepialidae, depending from fore-wing so as to grasp costa of hind-wing in jugal sinus.

or a true jugum, which is believed to form a finger-and-thumb clasp for the base of the costa of the hind-wing (Hepialidae). The very archaic little moths known as Micropterygidae, though abundant in New Zealand, are only represented by two species in Australia, the better-known one being *Sabatinca calliplaca*, from Mount Tambourine. Another species (*Anomoses hylecoetes*), originally described as belonging to this family, is now placed in a second family Anomosetidae, while the recently described *Palaeoses scholastica* forms the sole existing representative of the Palaeosetidae. Both these families are related to the Hepialidae.

The Hepialidae (swifts or wood-moths) have their headquarters in Australia, and are represented by a number of very large and handsome forms. The most striking is *Leto staceyi* (Bentwing Moth, fig. 14); the female of this moth expands up to ten inches. There are also a number of large species belonging to the genus *Charagia*, with green or pale blue fore-wings and white or rose-pink hind-wings. *C. ramsayi* is fig. 15. The larvae are wood-borers in the stems of *Eucalyptus, Acacia*, etc. The pupa is incomplete, and much resembles the pupa of the crane-flies. A number of less showy species, whose larvae feed on the roots of trees and grass, are contained in the genera *Pielus, Trictena, Porina, Perissectis, Oncopera* and *Hectomanes*.

In the sub-order Heteroneura the venation of the hind-wing differs from that of the fore, being reduced to eight veins at the most, exclusive of the anals. This is brought about by a distal fusion of Sc with R_1, and by the suppression of all the branches of Rs. The wings are either coupled in flight by means of a frenulum fitting into a retinaculum on the under-side of the fore-wing, or are kept in position simply by the overlapping of the dorsum of the fore-wing upon the enlarged costal area of the hind, as in



Frenulum and retinaculum in Heteroneura (males). In most females the frenulum consists of a number of bristles.

butterflies (q.v.) and emperor-moths (amplexiform types).

The most archaic family is the Cossidae, which, apart from the striking difference of venation, show considerable affinity with the Hepialidae. They are represented in Australia by 36 species, many of great size. The enormous *Xyleutes affinis*, with a wing-expanse reaching up to nearly 10 inches, and a huge cumbersome body as big as a small banana, is probably the heaviest moth in the world. The larvae of this family are wood-borers, mostly in large forest trees.

The peculiar family Castniidae is represented by about 25 species belonging to the genus *Synemon*. They are day-flying moths with clubbed antennae, and thus superficially resemble butterflies. But they possess a frenulum, and their venation is very archaic and quite unlike that of the butterflies. The imagines fly over grasslands, but nothing is known of their life-histories.

The super-family Tortricoidea (500 species) comprises several families of small moths related to the Cossidae, but somewhat more specialized. The dominant family Tortricidae (bell-moths) is well represented here by nearly 300 species. Many of these are exceedingly beautiful, as are some species of lesser-known families, such as *Bondia caseata* (fig. 16) belonging to the Carpocapsidae.

The super-family Tineoidea comprises about 3400 of the known Australian species, mostly small moths. The Oecophoridae, however (1500 species), contain some beautiful species, one of which, *Wingia lambertiella*, is fig. 17. The family Xyloryctidae (nearly 300 species), of which *Xylorycta porphyrinella* (fig. 18) is a fine example, have wood-boring larvae, some very destructive to fruit-trees. The Aegeriidae (clear-wings) are not well represented in Australia, but the small and delicately fringed Gracilariidae are more numerous. Quite a number of showy species belong to the Hyponomeutidae. The family Tineidae (400 species) contains small moths distinguished by the hairiness of their heads; the larvae of many of these latter (e.g. the genus *Xysmatodoma*) make cases which they carry about with them, like those of the Psychidae and caddis-flies. The Gelechiidae are extensively represented, more than 400 species being known.

The super-family Zygaenoidea contains four families found in Australia—the Psychidae (case-moths), the Limacodidae (cup-moths), the Epipyropidae, and the Zygaenidae (burnet-moths). About 25 species of Psychidae are known here, the largest being *Metura elongata*. The bags or cases formed by the larvae are often of elaborate structure and great interest; but the moths themselves are usually ugly, the females being wingless and never leaving their cases, while the males, which are much smaller, have wings poorly supplied with scales, and dash themselves about in the wildest manner as soon as they emerge. The Epipyropidae are an obscure group whose larvae feed upon plant-hoppers.

The Limacodidae are remarkable for their hard oval cocoons, which are neatly opened by the emerging moth, the empty cocoon resembling a cup. The larvae are slug-like, but beautifully coloured; many of them possess a series of urticating tubercles for defence. Our commonest species is *Doratifera longerans*, in which the sexes are very dissimilar in size and coloration. One of the prettiest of this family is *Monopla miltogramma* (fig. 19). Thirty-five species are known from Australia.

The Zygaenidae or true burnet-moths are not well represented in Australia, there being only 16 small species of bright green or velvety black coloration, resembling the forester moths of England. The place of the more typical and showy spotted burnets is taken by the Syntomidae, a specialized offshoot from the Arctiidae, discussed later on.

In the super-family Pyraloidea, the archaic family Thyrididae is represented by nearly 50 species, those of the genera *Rhodoneura* and *Addaea*, found in Queensland, being the best-known. The group of closely allied families Pyralidae, Pyraustidae, Crambidae, and Phycitidae are exceptionally abundant, there being nearly a thousand species, many of graceful shape and beautiful coloration—as may be seen from the two species figured, *Margaronia suralis* (fig. 28) and *Hyalobathra minialis* (fig. 29). One of the commonest is the prettily marked *Zinckenia recurvalis*, whose larvae feed upon saltbush. The aquatic caterpillars of the genus *Hydreuretus* are quite common in Australian rivers. They build cases out of reeds, and carry them about in the manner of caddis-worms. They breathe by means of filamentous gills thrown out from all parts of the abdomen. Little is known of the Australian species. The plume-moths (Pterophoridae and Orneodidae) are somewhat rare in Australia, only 36 species being known, of which six belong to the latter family or 'twenty-plumes.'

All the above represent the more archaic types of Heteroneura. We now come to the more specialized types, in which the cell is always completely formed, and the hind-wing has only two free veins below the cell.

The Lasiocampidae (eggars, lappets) are a very distinct family of which about 40 species are known from Australia. They are mostly grey or brown in colour, and have projecting palpi; our best-known genus is *Entometa*.

In the super-family Noctuoidea are included a number of allied families represented by nearly 1300 species in Australia, of which nearly 900 belong to the dominant family Noctuidae. Many of these latter are serious pests, their caterpillars (cutworms) destroying the roots of grass or vegetables wholesale. The most noteworthy species is the famous Bugong or Bogong Moth (*Agrotis spina*) which often appears in immense swarms in October, hiding in houses, where they may even blacken the ceilings and crawl into every corner and into the folds of garments. They also swarm in crevices of rocks and on the summits of mountains, where the aborigines used to search for them, sweeping them up in thousands and making them into a paste for food. Another large house-haunting noctuid is *Sericea*

spectans, mottled blackish with large eyespots on the wings; *Dasypodia selenophora* is a similar species found in Victoria. The fine moths of the genus *Ophideres* occur commonly in Queensland, where they suck the juices of citrus fruits and bananas. There are many handsome species of noctuids, particularly among the sub-alpine forms. The prettily marked *Fodina sarmentosa* is fig. 25, and the widely-spread tropical species *Paracrama dulcissima* fig. 24. The day-flying moths of the sub-family Agaristinae are known for their conspicuous colour-patterns. The most beautiful of these is the gaudy *Agarista agricola,* while the commonest and most destructive is the Vine Moth, *Phalaenoides glycinae.* The extraordinary Whistling Moth, *Hecatesia fenestrata,* has a peculiar zigzag flight at sunset, and the male makes a whistling noise, supposed to be caused by friction between the antennae and a clear membranous patch on the fore-wings.

The Drepanidae (hook-tips) are rare in Australia, only three species being known. The Lymantriidae (tussock moths), are much more numerous, 60 species being known. Most of these are grey, brown or fawn-coloured, without any special pattern. The Anthelidae include the fine genus *Chelepteryx,* with two very handsome species, one of which, *C. collesi,* reaches six inches in expanse. The larvae of this genus are solitary. Those of most of the Lymantriidae build large shelters in trees or bushes, in which they live gregariously. Their hairs, which are usually urticating, are spun into the fabric of their cocoons, thus making them dangerous to handle.

The small family Hypsidae connects the Noctuidae with the Arctiidae. Several common species occur, notably the day-flying black-and-white moth, *Nyctemera amica.*

The Arctiidae (tiger-moths, footmen) are abundant in Australia, with about 170 described species, mostly of the sub-family Lithosiinae or 'footmen.' Most of these are beautifully coloured in red or orange. Two examples are figured, *Castulo doubledayi* (fig. 21) and *Scoliacma bicolor* (fig. 22).

The Syntomidae (false burnet-moths), already mentioned when discussing the Zygaenidae above, are a specialized offshoot of the Arctiidae, their larvae being lichen-feeders. The adults are mostly black, with pink or orange spots, and closely resemble the true burnets in appearance, as may be seen from the figure of the common *Amata annularia* (fig. 23).

The Notodontoidea include two families, Notodontidae and Sphingidae. The first of these contains two sub-families. The Cnethocampinae include the processional moth *Ochrogaster contraria,* whose larvae may often be seen crossing a road in single file, two or three hundred at a time. Of the Notodontinae (prominents) about 70 Australian species are known, notably the large species of the genus *Hyleora,* whose smooth, green caterpillars feed on the foliage of eucalypts. The spotted white *Cerura australis* also belongs to this family. The Sphingidae (hawk-moths) are represented by about 50 species, many common, but most of them rare and striking forms, chiefly found in the tropics. In eastern Australia the gigantic *Coequosa triangularis,* beautifully marked in orange and brown, is one of the largest hawk-moths known; the female often expands over seven inches. *C. australasiae* is even more beautiful, but not quite so large. Both species are greatly prized by collectors. In Queensland there are to be found a number of species of the day-flying 'humming-bird hawk-moths,' with clear wings and tufted tails, belonging to the genera *Macroglossum* and *Cephonodes.* In *Cizara ardenia* (fig. 20), one of the most striking of the Australian hawk-moths, the combination of a rich, glossy, greenish-black ground-colour with delicate pink markings is unusual.

The super-family Geometroidea (loopers) is named from the well-known manner of progression of the caterpillars, which have only a single pair of pro-legs besides the anal claspers. Nearly 1000 species have been described from Australia. Of these, the Oenochromidae (Monocteniidae), the thorn-moths, include nearly 200, most of them very handsome species. The Boarmiidae (Selidosemidae) contain nearly 300 handsomely marked grey or brown species, with wavy bands on their wings, many being of considerable size. Their larvae, which are common objects in the bush, resemble short twigs or sticks. The Larentiidae (wave-moths) are smaller, often beautifully coloured or patterned with delicate tracery, especially the mountain species. The Geometridae or emerald moths are the most beautiful of all, and are well represented in Australia by 130 species. Two are figured, *Agathia laetata* (fig. 26) and *Uliocnemis partita* (fig. 27).

The Uranoidea contain only the two families Epiplemidae and Uraniidae. The former family includes small moths which, when at rest, twist their fore-wings into a roll, and mimic the attitude of a jumping spider. The Uraniidae are large day-flying moths, confined to the tropics. Superficially they resemble swallow-tail butterflies. Our commonest spieces, *Alcidis zodiaca,* is sometimes found in swarms resting on vines in the tropical scrub.

The Bombycoidea contain only two families, Bombycidae and Saturniidae, of which the former family is represented in Australia by four species only. The Saturniidae (emperor moths) are represented by eight large and handsome species, the commonest being *Antheraea cucalypti.* The caterpillar of this moth is spiny and very handsomely coloured, and is frequently found feeding on eucalypts. The largest species is the magnificent *Coscinocera hercules,* found only in northern Queensland and Papua. Measuring up to 10½ inches in expanse, this is probably the largest moth in existence.

Butterflies form a very distinct group, and are dealt with under their own name. R.J.T.

Leptospermum, a genus of the family Myrtaceae, consisting of shrubs or small trees with alternate leaves. It occurs in Australia and Malaysia, with two species in New Zealand: most of the Australian species are endemic. The calyx-tube is bell-shaped, with 5 herbaceous or membranous lobes; petals 5, orbicular; stamens numerous, in a single row; capsules opening at the top by valves; seeds (in some species) with transparent wings along their angles. The genus is difficult to classify, owing to the paucity of distinguishing characters. *L. laevigatum* is one of our best sand-binders, forming dense shrubberies on the coastal dunes. *L. scoparium* has pink or white flowers, resembling apple-blossom; those of *L. flavescens* are greenish-white. The leaves of the former of these species (called 'manuka' or 'scrub manuka' in New Zealand) were used by Cook's sailors at Dusky Bay, in conjunction with those of the spruce, to brew a kind of beer—and by themselves as a substitute for tea: those of the latter have been more commonly used for that purpose since

Cook's time (see TEA-TREE). Its essential oil has been found to contain 8 per cent of phenol. All the species produce much honey, and are haunted by a great variety of insects and birds. The wood of several species is used by natives to make kangaroo spears and spear-handles.

Leucopogon, a large genus of the family Epacridaceae, consisting of shrubs (rarely small trees); most of the species are endemic in Australia, but a few are found in New Zealand, Malaysia, and the Pacific islands. Of the 133 Australian species most occur in Western Australia. The flowers are white, densely bearded within and borne in short highly ornamental spikes or clusters; hence *Leucopogon* species are sometimes called 'white-beard.' *L. biflorus,* found on the coast and coastal ranges of New South Wales, is locally known as 'old man's beard.' *L. Richei* (Carrotwood) has small white succulent berries, upon which the French botanist Riche sustained life when lost in the bush on the coast of South Australia. The timber of full-grown specimens is of a deep orange colour, inclining to red; being hard, close-grained, and exceedingly heavy, it is used for the knees of boats. The tortuous, rough-barked branches are adapted for rustic work. *L. lanceolatus,* a tall shrub, and *L. amplexicaulis,* with heart-shaped leaves clasping the stem, have small bright red fruits. The wood of the former, as also of *L. melaleucoides,* is hard and beautifully marked.

Lewin, JOHN WILLIAM (1770-1819), is first heard of as a 'painter and drawer in natural history' who in 1798 persuaded the Duke of Portland, then colonial secretary, to give him a passage to Sydney. He arrived in January 1800, in H.M.S. *Minerva.* In 1801 Governor King attached him to the exploring party under Lieutenant James Grant (q.v.) in the *Lady Nelson,* which after an unsuccessful attempt to survey Bass Strait proceeded to the Hunter River and explored it as far as Mount Tangerin, about 9 miles east of Singleton. In November of the same year he went in the *Norfolk* to Tahiti, was shipwrecked there, and returned in the *Porpoise* at the end of 1802. He then settled at Parramatta, where he is noted as sergeant in the local volunteer force; his name figures among those of Hawkesbury settlers who signed a loyal address to Governor Bligh after the rebellion; and in 1810 Macquarie appointed him coroner at Sydney. But his main work was delineation of the natural history of the new country. In 1805 he published *A Natural History of the Lepidopterous Insects of New South Wales,* the plates for which were drawn and engraved in the colony by him; in 1808 he followed this up with *The Birds of New South Wales,* with plates also engraved and coloured by himself in the colony, though the letterpress was set up and the book was first published in London—where the title was altered to *Birds of New Holland.* (This book was reissued in Sydney in 1813 under Lewin's original title.) In 1808, also, he advertised himself as a portrait and miniature painter, and four years later he opened an 'Academy for Painting' in Sydney. Macquarie had a high opinion of his artistic powers; he presented Lord Castlereagh with one of his paintings of Sydney, took him on the famous journey across the new Blue Mountains road, attached him to Oxley's expedition of 1817, and wanted to send him with P. P. King in the *Mermaid.* When Lewin refused this last work as involving too long a separation from his family, Macquarie proposed to the British government that he should be permanently employed as government artist. Lewin died on 27 August 1819, and his widow was granted a pension of £50 a year. Some of his paintings are in the Mitchell Library at Sydney. Two were reproduced to illustrate Oxley's published journal of the 1817 tour. An enlarged edition of the *Birds of New South Wales* was issued in London in 1822; another, with many alterations and additions by later naturalists, in 1838. It is worth noting that his first book, the *Lepidopterous Insects,* was avowedly published 'to furnish the Author with the means of returning to England,' while in 1808 his wife had to run an inn and a shop: before Macquarie's time art was evidently no means of livelihood in New South Wales. See ART.

Lewis, SIR NEIL ELLIOT, born at Hobart on 27 October 1858, and educated at the local high school and at Balliol College, Oxford (B.A., 1882; M.A. and B.C.L., 1885), was called to the bar in London in 1883 and to the Tasmanian bar in 1885. Richmond sent him to the legislative assembly in 1886, and he retained the seat until federation. In 1892-4 he was attorney-general in the Dobson ministry, leader of the opposition in 1894-7, and premier in 1899; the interval he spent as a Tasmanian representative on the federal convention of 1897-8. For the first four months of 1901 he was a member of the first federal ministry (Barton's), without resigning his position in the State ministry; he then gave up the federal position, and remained premier till April 1903. He returned to office in 1909, and (except for about a week in that year) held it till 1912. From 1890 to 1912 he was on the council of the university of Tasmania (vice-chancellor 1903-9). He retired from politics in 1920. (C.M.G., 1901; K.C.M.G., 1902.)

Libraries, Public. *Victoria.*—The first free public library in Australia was that founded in Melbourne in 1853, the existence of which was made possible mainly by the zealous efforts of Redmond Barry (q.v.) and the active sympathy of Governor Latrobe. As early as 1842 Barry had set aside for a free circulating library one of the rooms in his cottage in Bourke-street-west; this contained a fair collection of standard works, which he had taken with him to the colony, and as many of the current English magazines as reached him and his friends. A few books and magazines could also be obtained from the mechanics' institute which was established in 1840. A sum of £13,000 for the erection of a library building and the purchase of books was voted by parliament in January 1853, and in the following July the first board of trustees was appointed, with Barry as chairman. The library was opened with 3846 volumes, for reference only, in February 1856; it was free to all persons over the age of 14 years. A. H. Tulk was the first librarian. In 1858 the establishment of an art gallery and museum in association with the library was considered, and in May 1861 a museum of art was opened in the library building. In 1865 the trustees concurred in the proposal of a commission of fine arts (appointed in 1863) that the public library, the galleries and schools of art, the museum of natural history and allied economic branches relating to science, art, and manufactures should be united to form one institution; they also approved of the suggestion that all the

buildings required for the combined institution should be on the site of the public library. On 29 December 1869 an act was passed to provide for the incorporation and government of the public library, museum and national gallery of Victoria. Until 1882 there was no subject catalogue of the books in the library, nor were there any special lists or indexes for the guidance of readers (except some rough 'bay catalogues'); but in that year a complete reorganization of the library was begun, though some years passed before the work was completed.

In April 1859 it was decided to introduce the system of circulating cases of books amongst municipal libraries and literary institutes, so as to afford a frequently changing supplement to the local collections. At first the experiment, which was put into operation in 1860, was confined to institutions within ten miles of Melbourne; in 1867 this limit was abolished, and cases were sent to country libraries. During 1922 3621 volumes were lent in this way throughout the State. The trustees frequently considered the advisability of establishing a lending branch, but were hampered by lack of funds and accommodation until 8 August 1892, when the lending branch was opened in temporary quarters in the newspaper room. In 1913 the library was moved from the galleries which it had long since overcrowded, and was housed in a new domed building, the central part of which is a magnificent circular reading-room. The library now contains in the reference department 298,000 volumes, besides a very large collection of newspapers; in the travelling libraries section 11,000 volumes; and 41,000 volumes in the lending branch.

New South Wales.—The origins of the free public library of New South Wales date farther back than those of the Victorian library, though its establishment as a public institution was later. In 1821, to lessen the inconvenience occasioned by the lack of books in the colony, a few leading citizens of Sydney devised an ingenious scheme whereby a consolidated catalogue was made of the books in their private libraries; this facilitated the borrowing of books from one another. But the scheme was necessarily limited in scope, and unable to meet the increasing demand for new books; on 3 February 1826, therefore, the Australian Subscription Library and Reading Room was established, the conditions of membership being drawn up with a view to keeping the library 'select.' The entrance fee was five guineas, the annual subscription two guineas; admission was by ballot, one black ball in four disqualifying the applicant. The original printed list of rules, officers and members is preserved in the Mitchell Library at Sydney. On 1 December 1827 the library, consisting of about 1000 volumes (some of which had been obtained direct from England and others locally by gift or loan) was opened on the first floor of No. 1 Terry's Buildings, Pitt-street. The first librarian was Peter Cooke, and he also acted as dispenser of the Sydney dispensary (see HOSPITALS), which occupied the ground floor of the same building. Governor Darling strongly favoured the movement, and his aide-de-camp Lieutenant de la Condamine was the first secretary of the institution. In the first order for books sent to London the great quarterlies had precedence; then came standard works on history, theology, biography, science, and travels; Scott's novels were the only books of fiction. In a couple of years, however, the committee had to yield to the weaker tastes of many subscribers and order the works of 'Bulwer, Dickens, and Lever' and 'any other recent novels which have been reviewed and approved by the writers of the *Edinburgh* or *Quarterly Reviews.*' In 1830 the committee, claiming to have laid the foundations of a public library, asked Darling for a grant of a town allotment, and suggested that the museum (then in an embryo state) should be combined with the library. Darling was sympathetic, and authorized the committee to select two allotments of ground in Hyde Park as a site for the library, on the understanding that suitable provision should be made to house the museum in the proposed new building; he also authorized the selection of two allotments at Rushcutters' Bay, from the sale of which the committee might obtain the funds necessary to carry on their work. The grants were selected, but not confirmed during Darling's term of office. In 1834 Governor Bourke confirmed the grants at Rushcutters' Bay, but substituted others for the Hyde Park allotments, a change which the committee refused to accept; finally they accepted a grant of the site at the corner of Bent-street and Macquarie-street on which the public library now stands. Before the land was conveyed to the society, Bourke formed the opinion that it would be unwise to house the museum in a building belonging to a private society, and suggested that the grant should be cancelled and the government should erect a building with library accommodation; if at a subsequent date the society were required to vacate the premises, it should receive a building allotment or its equivalent in money. In 1838 £4000 was voted to erect a public library and museum; but before commencing operations the government required some assurance that the public should have free access to the books, whereas the committee maintained that, if the institution was to be transformed into a public library, the government should purchase the books, fittings, etc. on which about £3000 had been spent. On 25 October 1838 the committee agreed to set aside a special room for the use of non-subscribers, who would be allowed access to the books for reference; they were of the opinion that the expense of an extra librarian should be met by the government. As the governor would not agree to this proposal the land-grant reverted to the committee in May 1841, and a new building was completed in November 1845. For many years the library had been unsuitably housed. In 1831 the books were removed from the Pitt-street building to rooms provided by the government at the old post-office in George-street, and thence (*a*) to a house in Bridge-street not long vacated by the chief justice, (*b*) to a small annexe to St. James's parsonage in Macquarie-street and (*c*) to rented rooms in Macquarie-place. The only important change made in organization during this period was the incorporation of the library in 1834, and the appointment of trustees; in the same year a first attempt was made to classify the books. The library was seriously hampered by financial difficulties, to meet which Dr. Lang in 1844 proposed that the system of balloting for members should be abolished, and the subscription fee reduced to £1 per annum. This suggestion, though defeated at the time, was partially adopted in 1852, when admission by ballot was discontinued, the nomination of three proprietors being accepted in its place. To widen the basis of admission still further, an act of council was passed whereby the library was formed into a proprietary corporation of 1000 shares of £25 each, the annual subscription being £1 a share.

Shareholders were entitled to a separate frank or token for each share held; these were transferable, and on presentation admitted the bearer to the reading-room—the object being to afford access to the public for reference purposes and to encourage the impression that the institution was in a way a public library. Indeed in 1857 the government recognized the importance of the library by placing in it the English patent law commissioners' publications, about 200 volumes in all. But these expedients did not place the institution on a satisfactory footing, and towards the end of 1859 the trustees urged the government to buy the whole property for £15,000. William Forster, then premier, favoured the proposal, but his ministry went out of office before any decisive action was taken. In April 1862 negotiations were entered into with the works department to convert the premises into government offices. The committee hoped to sell the books and fittings, as well as the building and land, to the government, for it was known that the legislative assembly favoured the establishment of a public library, £25,000 having been voted for that purpose in the previous January. When, however, this proposal was placed before parliament, it was defeated, the library being condemned for its exclusiveness. The shareholders thereupon agreed to a suggestion of P. J. Elliott, then librarian, that he should rent the library from them for £300 a year, and he opened it as a private enterprise under these conditions on 1 January 1864. The experiment was a failure. In April 1866 a private act authorized the reconstruction of the company, shares being written down from 1000 of £25 each to 2000 of £5; this also failed to put matters straight, and the entire property was offered to the government for £8000. On 12 March 1869 the legislative assembly agreed to the purchase, but the decision was not acted upon until September, when the government paid £1500 for the books and £3600 for the building—a sum barely sufficient to cover the trustees' financial obligations. A probably determining influence in favour of the purchase was the fact that the executors of the will of Judge Wise had handed over to the government his library of books, pamphlets, and papers, to be placed in the 'free public library' as soon as one was established; this library of about 6000 volumes included a number of Australian books and newspapers, a section in which the subscription library was very weak. The new free public library was opened on 30 September 1869 as a reference library; it contained about 20,000 volumes, but a number of these were removed from the shelves as being a lure to idle and frivolous persons. In 1885-6 a wing facing Bent-street was added, and in 1889 the rest of the building was remodelled uniformly with the new wing. On 30 June 1924 the reference library contained 216,810 volumes.

The establishment of a lending branch of the library was discussed as early as 1874, but was generally considered impracticable until the library was more suitably housed. Nevertheless a lending branch was established in 1877, but had to be removed to a separate building in 1881; in 1908, under the Sydney corporation amendment act, it was vested, with all its books, papers, and fittings, in the city council of Sydney, which entered into possession in October 1909. This lending library, the only important municipal library in Australia, extended its functions in 1915 to include a children's section. During 1923 the library issued 446,646 books to 22,516 borrowers.

In 1883 a country circulating department was established as a branch of the public library, and boxes of books were sent to literary institutes in the country districts. This department is now divided into the country circulating section and the country reference section. The circulating section was extended in 1919 to include boxes of children's books for small country schools, 50 boxes (each containing about 35 books) being equipped and sent out by the end of 1920. In June 1924 28,973 books were circulating in this way. The country reference section was established in 1913, with the idea of supplying directly to individual borrowers 'definite information on a definite subject;' in June 1924 it contained 10,172 volumes.

Of the gifts and bequests made to the library the most valuable single gift is a first folio edition of Shakespeare, presented in 1885 by Richard and George Tangye of Birmingham. On 17 October 1898 David Scott Mitchell (q.v.) communicated to the trustees his intention of bequeathing to the library his large collection of Australian books, pictures, maps, engravings, and manuscripts—many of which are invaluable—on the sole condition that the government should take early steps to erect a suitable building, with provision therein for keeping his collection by itself and making it freely accessible to students of Australian history under regulations similar to those obtaining at the British Museum. Nothing was done by the government until 1905, when the condition was accepted; the Mitchell wing, begun in 1906, was officially opened in March 1910. For fuller details of the Mitchell Library see the biography of its founder.

To emphasize the value of the public library to the business community, a special exhibition of technical and commercial literature was held in Sydney by the trustees in July-August 1919; as a result of the increased interest aroused, a special research department was created, and a staff appointed to collect material needed for special inquiries, especially of an industrial character.

In May 1919 William Dixson offered to the trustees of the library a number of important historical pictures—including Sir Joshua Reynold's portrait of Captain Cook and Gilbert Stuart's of Lord Sydney—on condition that a gallery to accommodate them was added to the Mitchell Library building. In April 1924, no advantage having been taken of the offer meanwhile, he repeated it, adding that at his death the whole of his Australian manuscripts, books, and pictures would be handed over to the library on conditions similar to those applying to the Mitchell collection. On 17 December 1924 the offer was accepted, provision being made by act of parliament for the eventual erection of a national library adjoining the Mitchell building and the immediate addition to that building of a wing for the reception of Dixson's pictures—to be known as the William Dixson gallery.

In 1851 a committee was appointed by the senate of the university of Sydney to form a library about the small nucleus of volumes purchased from the collection of Dr. Mackaen. By purchase and bequest the library had grown to a considerable size by 1885, when Thomas Fisher of Sydney bequeathed £30,000 'to be applied and expended by the senate in establishing and maintaining a library for the use of the University.' As a building to house the existing collection was urgently required, the senate decided to divide the bequest into two parts, £10,000 to

be reserved as a perpetual endowment fund for maintaining and adding to the library, and £20,000 to be set aside for the erection of a building to be designated the Fisher library. As the building fund was insufficient to provide the necessary accommodation, the government was asked to subscribe a similar sum, but the proposal was not seriously considered until 1900, when it was referred to a parliamentary standing committee of public works. As a result of the committee's report, the government decided to meet the whole cost of the proposed library buildings, leaving the Fisher fund and its accumulations to be a perpetual endowment for library purposes. The new building was opened at the end of 1909. A munificent bequest of books and manuscripts has recently been received from the library of Sir Charles Nicholson (q.v.).

South Australia.—The South Australian Institute, whose library was available for circulation only to subscribers but could be freely used by the public as a reference library and reading-room, was established by act 16 of 1855-6. The institute itself resulted from an amalgamation of a mechanics' institute (founded soon after the establishment of the colony) with a subscription library. In 1859 the institute developed a system of travelling libraries, and claims to have been the first library in the world to circulate books in this way. By an act of 1884 the institute was merged in 'The Public Library, Museum and Art Gallery of South Australia,' controlled by a board of 14, five of whom were appointed by the governor and nine elected by various educational societies. The board now has under its control five departments—administration, public library, museums, art gallery, and archives. The archives department was established for the collection of original documents likely to be of service in compiling a history of the State. To assist in the development of this department Professor G. C. Henderson of Adelaide was in 1914 commissioned by the South Australian government to report on the system of keeping archives in England, France, Belgium, Holland, and Ceylon; he also obtained valuable information from the United States and Canada. A suitable building for housing the documents and staff was provided in 1921. In 1922 the archives contained 171,227 documents, 4298 photographs and 97 maps.

The public library has no circulating or lending department, but the government subsidizes the Adelaide Circulating Library, a subscription library established under the act of 1884. A children's section was opened in 1915, and lectures are arranged. On 30 June 1923 there were 122,647 volumes in the library, 118,010 of which were in the main library, 2550 in the duplicate Australian collection and 2087 in the children's section.

Tasmania.—The public library of Tasmania, though small, has had an interesting history. In 1849 a subscription library was founded under the patronage of Sir William Denison, who placed a sum of £100 on the estimates for the purchase of books. On 25 August 1850 the books and property were vested in trustees 'for the use of the public;' but it was not until 1859, after parliament had voted a subsidy of £ for £ subscribed (in addition to £200 already granted) that the public was allowed free access to the library. Unfortunately, as soon as the library became free the number of subscribers fell off and the additional subsidy was withdrawn; the trustees were thereupon obliged to limit the privileges of the institution to subscribers and honorary members, and in June 1867 had to close it down. It was reopened in 1870 under the joint control of parliament and the municipal council, which had made suitable provision for housing it in the new town-hall building. An act passed during the year provided for the incorporation and government of the Tasmanian Public Library; control was vested in eight trustees, four elected by the governor-in-council and four by the municipal council. In 1902 the trustees decided to take advantage of the offer made by Andrew Carnegie to pay for the buildings and fittings if the corporation would grant an adequate site for a free public library and provide the necessary funds for its maintenance. In 1903 Carnegie undertook to pay £7500, under certain conditions as to site and maintenance, stipulating also that a department should be established for lending books free of charge. A lending branch was opened on 4 July 1907, the additional cost being met by increased grants from parliament and the city council. In 1922 a country circulation branch was opened and a children's library established. In 1923 the library, with an income of £1600, contained 25,000 volumes; the number of issues from the lending branch amounted to 32,000.

Western Australia.—There was no public library in Western Australia before 1889, though the government gave small subsidies to the Perth mechanics' institute (founded in 1851) and the Fremantle literary institute. To commemorate Queen Victoria's jubilee in 1887, the government founded the 'Public Library, Museum and Art Gallery of Western Australia;' the library was the first section opened, in January 1889. It is a public reference library only, but cases of books from a second collection are sent out on loan to country institutions; 201 institutions were served in this way during 1922-3. Since 1914 only small annual additions have been made to the library stock, which in June 1923 comprised 132,767 volumes in the reference section and 15,910 in the circulating section.

Queensland.—The Brisbane Public Library was formed in 1886, its nucleus being a small private library purchased by the government in 1895; the management was vested in a board of trustees. The name was changed to 'The Public Library of Queensland' in 1898, though the institution was not officially opened to the public until 1902. In 1906 the board of trustees was dissolved, and from that time onwards the library has been administered directly by the government as a branch of the public service. It is a reference library only. In 1923 it contained 32,700 volumes.

The Commonwealth National Library.—The library committee appointed by the first federal parliament in 1901 recognized the necessity of making collections for a library which would be useful to members when the federal capital was established. In 1902 the acquisition of books for a Commonwealth parliamentary library was therefore begun, special efforts being made to secure books, records, and maps of Australasian interest. In 1908 negotiations were opened with E. A. Petherick for the acquisition of his Australasian collection, comprising about 10,000 volumes; it was taken over in 1909, the agreement being ratified by parliament in 1911, and Petherick remained in charge of the books until his death in 1917. The committee then decided to subdivide the library into a parliamentary section and an Australasian section, the latter to be developed into a national library for Australia. In 1923, when the Commonwealth government purchased for the library Captain Cook's manu-

script journal of his voyage in the *Endeavour* and four other very valuable Cook documents, the Australasian section was definitely entitled 'The Commonwealth National Library.' In the plans for the federal capital provision has been made to accommodate the parliamentary section in the parliament house, and the national library in a separate building adjacent to it; both sections will, however, remain under one control.

In 1912 the library committee undertook the publication of the *Historical Records of Australia*, of which 30 volumes have now been issued; the committee also publishes a *Commonwealth Parliamentary Handbook*. A classified and author catalogue of the library, exclusive of the Petherick collection, was issued in 1912.

By a provision of the Commonwealth copyright act of 1912 the publisher of any book, pamphlet, etc., printed in Australia is required to supply a copy to the library.

At the end of 1924 the two sections contained between them 67,000 books, 6000 pamphlets, and 2000 bound volumes of newspapers; the library also possesses a fine collection of early Australian documents, maps, pictures, and engravings.

Lice. See BITING-LICE, SUCKING-LICE, and HEMIPTERA.

Lichens, the popular name for vegetable growths composed of certain algae and of fungi supposed by some authorities to be parasitic on them. They are certainly of composite structure; the vegetative thallus is formed of hyphae embracing certain green or blue-green algal cells, whereas the reproductive organs are identical with those of various families of true fungi. The algal cells (gonidia), by means of their chlorophyll contents, form organic carbon compounds by which the fungal cells benefit, but here the true parasitism ends. With the exception of one or two species of *Endocarpon* (an aquatic form) they are regarded as air plants, and take large amounts of CO_2 from the air, deriving no food-supply from the rhizoids by which they cling to rocks, tree stems, old wood-work, etc. They thus differ from fungi, which obtain their nourishment from either living or decomposing animals and plants. Moreover the gonidia are capable of separating from the thallus, and of growing by themselves like free green algae. They have the widest distribution of any plants, being found from the seashore to the highest mountain top and from the equator to the poles. Their utility in nature is due to their peculiar power of burrowing into the hardest of rocks—even flint, glass, or granite—and making for themselves homes in the form of foveoli, thus preparing the way for the reception of larger forms of plant-life. This power is furnished chiefly by the carbonic acid absorbed from the air. Bachmann's observations show that under the attacks of lichen tissue granite is somewhat rapidly decomposed into a clay-like substance; quartz elements, however, are strongly resistant. Limestone, when attacked by the hyphae of *Chroölepus* algae, is perforated and becomes sponge-like.

For purposes of classification the systematic place of the various species depends largely on the relation of the lichen-forming fungus to the lichen algae. The reproductive organs (apothecia) found on the surface of the thallus form the basis of classification, and require microscopic study. They are of several colours and of widely different forms (e.g. semi-globular in *Calicium*, peltate in *Usnea*, plate-like in *Parmelia* and *Sticta*). According to Bruce Fink, lichen spores germinate and attack the free algae as other fungi attack their hosts. Northern New South Wales, Queensland, and Fiji are alike characterized by the number and similarity of their epiphyllous lichens. Many species contain gonidia resembling those of *Chroölepus* algae, especially those found on branches in mangrove swamps. The alga *Chroölepus umbrinus* is found in no less than 13 genera of lichens—or at any rate the algal symbiont of those lichens, if not of that species, resembles it most remarkably. The great majority of our lichens are associated with *Protococcus* or closely allied genera, the algae (usually bright green) that are seen on damp stones, fences and trees. The blue-green algae (Myxophysceae) are distinguished by their colour and gelatinous cell-sheath; the hyphae as a rule permeate the sheath, leaving the cell intact. This type of contact prevails in *G. glaeocapsa* and allied algal forms. See ALGAE.

Light, WILLIAM (1786-1839), was the eldest son of Francis Light, master of an East Indiaman, who married a daughter of the native chief of Kedah in the Malay Peninsula and received as her dowry the island of Penang; this he handed over to the East India Company, renaming it 'Prince of Wales Island' and stipulating for an annual subsidy to his father-in-law. William Light was sent by his father to England in 1792 and placed under the care of George Doughty of Theberton Hall in Suffolk: in 1800 he joined the navy as midshipman aboard the *Clyde* frigate, saw service in eastern waters, and was for a short time prisoner of war in France. In 1808 he left the navy to join the army (cornet of dragoons, 1808; lieutenant, 1809; captain of infantry, 1814; brevet-major, 1817), and served through the Peninsular war at first in the 4th dragoons, afterwards as an intelligence officer on the staff of the Duke of Wellington; Napier relates several anecdotes of his remarkable courage and resource. Leaving the army on 3 May 1821, he travelled in Italy and Sicily, and in 1823 joined as colonel the Spanish 'constitutional' army, which was defeated by French intervention in Spanish affairs under the aegis of the Holy Alliance. Light's next travels, in Turkey and Egypt, resulted in his joining the Egyptian navy at some time in the early thirties: there he met Hindmarsh (q.v.), and, when the latter was chosen to be governor of South Australia, was appointed surveyor-general to that colony. Sir Charles Napier, to whom the governship had been previously offered, strongly recommended Light for the post, but Hindmarsh had already obtained the appointment.

Sailing in the brig *Rapid* (which he navigated himself), Light landed on Kangaroo Island on 21 August 1836, and at once set about finding a site for the capital of the new colony. By the end of the year he had decided on the location which Adelaide now occupies, and successfully maintained his decision against Hindmarsh's preference for Port Lincoln and Jeffcott's for Encounter Bay. During 1837, however, he quarrelled with the London commissioners (who thought him too leisurely in his work), and on 2 July 1838 resigned his post to become the head of a private firm which undertook the survey of Port Adelaide. In memory of his childhood he named his house 'Theberton Cottage;' but an unfortunate misprint in the preface to his published journal has perpetuated

the spelling 'Thebarton.' On 22 January 1839, while he was preparing this journal for publication, a mass of personal documents dealing with his whole European career was accidentally destroyed by a fire which destroyed his house. The shock gravely impaired his already undermined health, and he died on 5 October 1839. He was buried in Light Square in Adelaide, and in 1843 a Gothic cross—designed by G. S. Kingston (q.v.)—was erected over the grave: this monument, having been much damaged by the climate, was replaced in 1905 with a granite pillar. Light is also commemorated by a statue in Victoria Square and a portrait in the Adelaide art gallery.

Light has been described as 'the Admirable Crichton of the early 19th century,' and Napier in his *Peninsular War* mentions 'the variety of his attainments—artist, musician, mechanist, seaman and soldier.' The portrait just mentioned is of Light's own painting, three of his water-colours are in the same gallery, and he published in England *Sicilian Scenery* (1823) and *Views of Pompeii* (1828), with engravings made from his own sketches. His *Brief Journal*, published in Adelaide in 1839, covers only a year or so of his voyage to and life in South Australia, later records having perished in the fire already mentioned.

See Thomas Gill's *Colonel William Light, the Founder of Adelaide* (Adelaide, 1911).

Lighthouses on the Australian coast may be divided into two classes, those that protect inter-State and coastal traffic, and those that merely indicate the entrance to a port. The lighthouses of a permanent character have been for the most part constructed in massive concrete or masonry, and contain lights varying from 500,000 to 1500 candle-power. Their distance apart depends largely on the amount of shipping affected. On the coast of New South Wales the average distance is 32½ miles, and in many instances one light is not lost until the next becomes visible; on the Victorian coast the average distance is 62 miles. On the Queensland coast the average distance is 107 miles; but this includes the long unlit stretches of the Gulf of Carpentaria—on the east coast the distance is only about 64 miles. In South Australia the average distance is 90 miles; in Western Australia and the Northern Territory the distances average 218 miles and 1040 miles respectively. The Tasmanian coast is fairly well lighted, the average distance being 60 miles. The positions of most important Australian lighthouses are noted in GEOGRAPHY, ECONOMIC, q.v.

During the past 20 years the character of the lights exhibited has been frequently altered from fixed to flashing, and from slow flashes to quick flashes. The tendency, however, is to adopt the innovation in all positions, regardless of circumstances; the difficulty of obtaining bearings to a quick-flashing light seems to be lost sight of. In many cases a fixed or slow-flashing light is much more desirable—especially in long channels, where a number of lights can be seen at once, and it is frequently difficult to ascertain the vessel's position in the channel.

The inferior translucency of coloured glass considerably curtails the visible distance of coloured lights: in some instances, therefore, coloured celluloid films have been substituted for coloured glass, with good effects. But in important positions coloured lights should not be used at all.

The use of acetone for unattended lights has much increased their reliability. With occulting gear, and by using the sunlight as an extinguishing agent, these lights now run for as long as 12 months with one charge of acetone. Some trouble was at first experienced with seabirds, but this has been largely removed by the use of fine wire screens to prevent birds from landing on the lanterns. Lights of this character are largely used on the Australian coast, more especially in Spencer and St. Vincent gulfs, to indicate shoals and changes of direction for channels. Acetone, however, is cheap only for quick-flashing lights with a correspondingly long dark gas-saving period.

Historical.—The first lighthouse erected in Australia was that placed by Macquarie on the outer South Head of Port Jackson, close to the present lighthouse. He laid the foundation-stone on 4 June 1816, but did not report the completion of the 'Very Elegant and Strong Stone Tower and Light House' until 16 May 1818; Bathurst promptly rebuked him for spending so much money on it. Greenway the architect, who supervised the construction, was rewarded with a conditional pardon. According to Oxley's report, 'Macquarie Tower and Light' stood 76 feet high on a spot 277 feet above the sea, and the light could be seen from a vessel's deck on a clear night 24 miles away. The expense of maintaining it was met by a charge of 2d. per ton on all vessels entering Port Jackson except such as were registered in New South Wales; and one of the earliest results of its completion was the making of the Old South Head road 'from Sydney to Macquarie tower, South Headland, 7 Miles with 11 Bridges.' In 1846 the administrator of the Port Phillip settlement bestirred himself for the safety of vessels moving along the coast in his charge, and sites for lighthouses were chosen on Gabo Island and Cape Otway; and in 1857 the South Australian government erected its first important lights on Capes Borda and Northumberland.

T.E.B.

Lignite. See MINERALOGY.

Liliaceae, a family of plants widely distributed in warm and temperate regions, with 45 genera and 189 species recorded in Australia. The genus *Asparagus* is represented by an indigenous species, *A. racemosus*, the roots of which are used medicinally in India. *Eustrephus* has also a single species, *E. latifolius*, endemic in Australia; it is a leafy climber with small fringed flowers and orange-coloured berries, which produces small edible tubers. *Rhipogonum* has one species (*R. scandens*, the Supplejack) in New Zealand; the rest are endemic in Australia. They are tall climbers, usually armed with prickles that enable them to climb large trees; the prickly species are popularly known as lawyer vines. The single species of *Dracaena*, *D. angustifolium*, is indigenous; that of *Geitonoplesium*, *G. latifolium*, is endemic. The latter has a glossy blue-black berry, and its young shoots are a fair substitute for asparagus. *Milligania* is a small genus of densely tufted woolly herbs, exclusively Tasmanian, with loose spikes of membranous flowers. *Allania* is an endemic genus of one species, *A. Endlicheri*. It is a small herb with matted intricate thread-like leaves and small clusters of white flowers, growing in fissures of the rocks in shady gullies, in a small area of the Blue Mountains. See ASTELIA, BULBINE, CHRISTMAS BELLS, DIANELLA,

GRASS-TREES, SMILAX, STYPANDRA, THYSANOTUS, XEROTES.

Lilley, SIR CHARLES (1830-1897), born at Newcastle-on-Tyne on 27 May 1830, educated at University College, London, and for some time articled to a London solicitor, migrated to Queensland in 1856 and, while still practising his profession, edited the *Moreton Bay Courier*. When Queensland in 1859 became a separate colony, Lilley was elected to the first assembly by Fortitude Valley (a suburb of Brisbane), and remained member for that constituency until he abandoned politics in 1874. In 1865 he took the attorney-generalship in the Herbert ministry and retained it under Macalister until August 1867, with the exception of three weeks in 1866 when R. G. W. Herbert (q.v.) resumed the premiership. On 25 November 1868 he himself formed a ministry, which lasted till 3 May 1870, and broke up because Lilley on his own responsibility ordered a government steamship to be built in Sydney against the wishes of his colleagues. When nearly four years later (in January 1874) his party came into power again, he refused to take office, and was made temporarily a judge of the supreme court; the appointment was confirmed in the following July, and in 1879 he became chief justice of the colony. In February 1893, having been accused by Sir T. McIlwraith of indiscretion in private references to cases on which he was adjudicating, he retired from the bench on a pension, and died on 20 August 1897.

Lilley was from the first much in advance of his time as a politician. Thirty years later he would have been a Labour leader; in the sixties he was regarded with suspicion as an extremist even by his own followers. On one subject, however, he was listened to with submission; his views on education, during both his parliamentary and his judicial career, had a dominating influence on the educational policy of the colony. He was instrumental in founding the Brisbane grammar school, and was for many years chairman of trustees of the school. In 1874 he was chairman of a royal commission on education whose report was embodied in the education act of 1875—that which established free, secular, and compulsory education in Queensland, and created the department of public instruction. In 1888 his name headed the signatures on a petition for the establishment of a local university; in 1891 he was chairman of a royal commission on this subject, and reiterated his persistent opinion that 'all our public education should be free ultimately.' Among other notable doings may be noted his initiative in creating a ministry for goldfields to help the mining industry, his active support of the Labour party by laying the foundation stone of the Brisbane trades hall while still chief justice (1891), and his extraordinarily active influence on legislation while out of office. It was, for instance, as a private member that he in 1870-1 forced through the bill substituting a simple for a two-thirds majority in the case of bills affecting popular representation in the assembly. He was also, as attorney-general, a member of the royal commission which in 1866-7 revised the statute law of the colony. (Kt. Bach., 1881.)

Lilly-pilly. See EUGENIA.

Limestone Caves. Limestone honeycombed by caves covers wide areas in all the Australian States. It generally outcrops in bold and picturesque cliffs or ranges of Palaeozoic age, although it is found also in beds which range from Recent to pre-Cambrian times. Owing to the intrusion of igneous rocks, the limestone in many places has been changed into white or coloured marbles of fine quality.

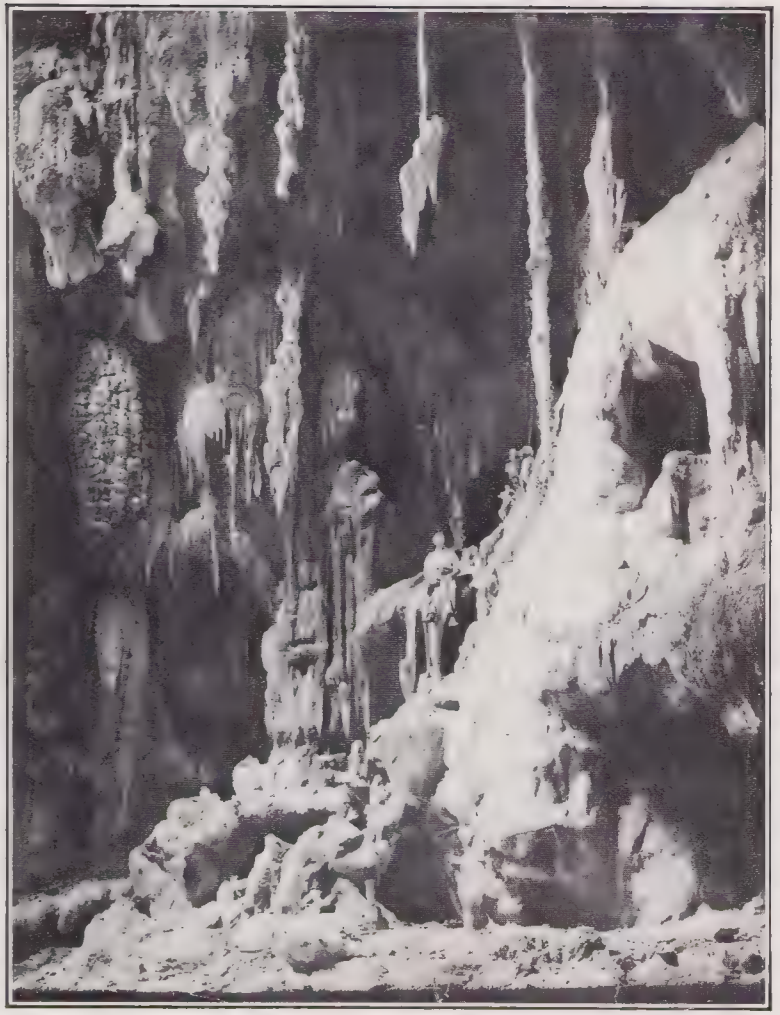
Australian caves are remarkable for their number, extent, and beauty. Stalactites, stalagmites, and columns, curtained and floored with sparkling dripstones, alternate with banded draperies like shawls. Some growths are translucent, others snowy white or tinted with colour. There are 'coral bowers,' 'fairy grottoes,' and white, cream, or amber-tinted 'cascades.'

A stalactite first appears as a slender, reed-like tube, and lengthens at the lower end until choked by lime; then deposition takes place on the outside, forming concentric rings that are distinctly marked when a little iron is present in the lime solution. Crystallization, fibrous and radiating, appears to take place coincidently with deposition, but in many cases is subsequently re-arranged and obliterated by the rhombohedrons of calcite. The presence of aragonite has not yet been determined, although this form of crystallization has been found in American caverns. Irregular or intermittent supplies of the lime-charged water, capillary attraction, and consequent changes in the rates and stages of crystallization, tend to decorate the stalactites with sprays and nodules like coral, and in other respects to alter their contour. The same causes are probably responsible for the groups of lime tendrils which simulate the twisted stems of a climbing plant, or the finest filigree work, and are known as 'helictites' or 'mysteries.'

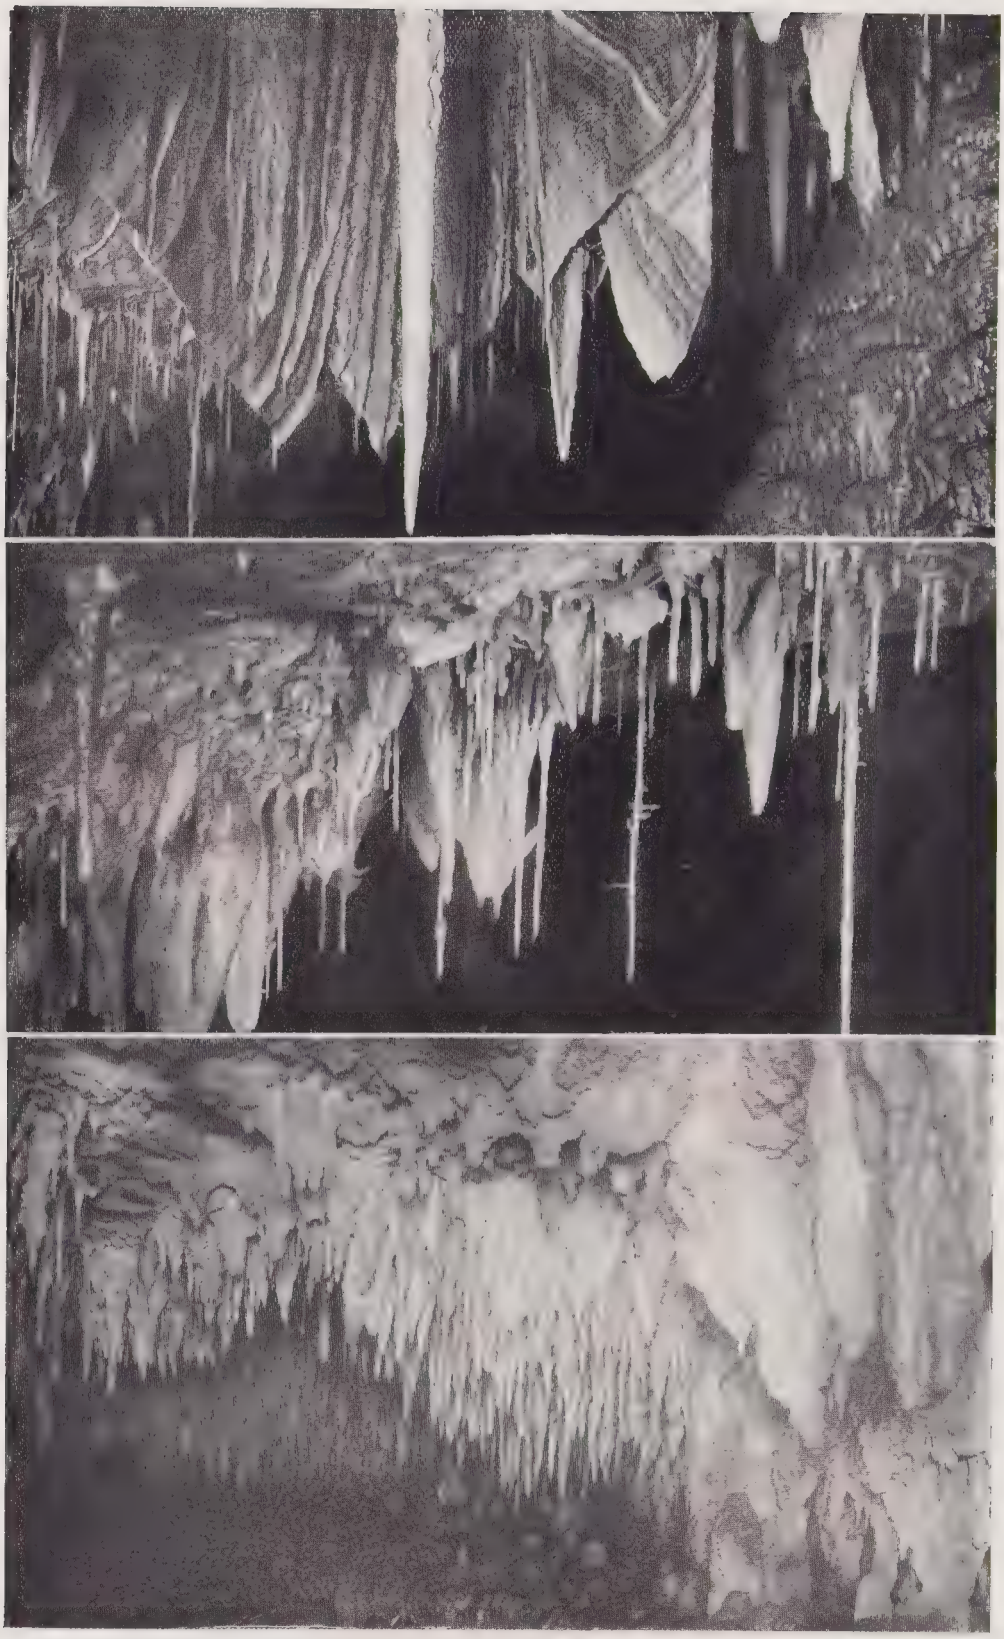
Stalagmites built up by the drip from overhanging stalactites are more regular in shape than those which obtain their supply of lime directly from the roof. Many roof-supplied stalagmites are of great beauty, being terraced by a series of inverted cones, which glisten with crystals on their upper edges but merge downwards into surfaces tinted with cream or amber. Basins and cavities that in the past have been periodically filled with water often exhibit myriads of clear (or tinted), semi-translucent, acute rhombohedral (occasionally scalenohedral) crystals, which form 'jewel caskets' and 'flower gardens.' In some of the shallow basins thin films of lime, which at first floated on the surface of the water, have broken and fallen in flakes that now imitate beds of down. Freakish mimicry of animate and inanimate objects is also of frequent occurrence. About the time taken in forming these curiosities we have no reliable data.

In *New South Wales* the caves near Wellington were described and mapped by T. L. Mitchell as far back as 1833. Four of the many other series discovered since then have been taken over by the government, which has made them easy to reach and comfortable to stay at. The chief series is at Jenolan (q.v.). The next in importance is at Yarrangobilly in the Muniong Range, 3200 feet above sea-level. It is reached by rail to Cooma (265 miles from Sydney) and a 65-mile drive thence by motor-car, or by rail to Tumut (318 miles) and a 47-mile drive. Caves open for inspection are the Glory Hole, the Jersey, the Harrie Wood, the Castle, and the Jillabenan. Like the Jenolan caves and those yet to be mentioned, they occur in Silurian limestones. At Wombeyan in the Main Range, almost due west of Mittagong, the limestone has been altered to a white marble; the caves

SHAWLS, BUCHAN CAVES, VIC.



CHILLAGOE. CAVES, Q.



1. FOLDED SHAWL, WALLINGUP CAVES, W.A.
2. NARRACOORTE CAVES, S.A.
3. MOLE CREEK CAVES, TAS.

are 1900 feet above sea-level, and are reached by train from Sydney to Mittagong or Bowral and a drive thence of about 42 miles. From Goulburn they are 50 miles by road. Caves open for inspection are the Creek (through which the Wombeyan Creek finds its way in flood-time), Fig-tree, Wollondilly, Kooringa, Guineacor, Junction, Forest Creek, Tinted, and Basin caves. The last-named is remarkable for a series of stalagmitic cavities shaped like swallows' nests, which vary in size down sloping walls until one of them (named 'The Royal Tub') is five feet deep and 3½ feet broad. Water passing over the sloping rock scoured out cavities; the liberated lime formed ridges on the outer rims of the cavities, and ultimately built up semi-circular walls decorated with crystals. The Wellington caves, five miles from Wellington on the western railway, are controlled by the local authorities, and are chiefly remarkable for their fossil remains, among which the following have been found:—*Diprotodon australis, Nototherium, Thylacoleo, Macropus,* and *Thylacinus* (Tasmanian wolf). At these caves mining for phosphates was at one time carried on. The Abercrombie caves, 26 miles south of Newbridge near Bathurst, consist mainly of a beautiful archway through which Grove Creek passes. Cathedral, Grove, and the Palace caves, and King Solomon's Temple, are also known, but are at present unimportant. They may be reached from Newbridge (26 miles) or Bathurst (43 miles).

In *Victoria* only the Buchan caves have been prepared for the reception of visitors. They are reached by rail from Melbourne to Sale (128 miles) or Bairnsdale (171 miles) thence by steamer through the Gippsland lakes and rivers, and finally by coach; they are 111 miles from Sale, 64 miles from Bairnsdale. They occur in an area of Devonian limestone that covers 70 square miles. The Fairy, Moon, Royal, Kitson, and Spring Creek caves are close to the township of Buchan; the Wilson lies to the east, the Murrindah and Lilypilly 2 miles north, and the Slocombe 11 miles north-east, near the Snowy River.

In *Queensland* limestone outcrops occur in many places, but its caves are for the most part unexplored. In the limestone belts between Brisbane and the Palmer River the best-known caverns are Olsen and Johannsen's, in Devonian limestone, 16 miles north of Rockhampton, and the Chillagoe, in Silurian limestone, about 140 miles west of Cairns. The latter include large chambers of considerable beauty. Caves of great size, one containing a remarkable subterranean lake, have been found 12 miles east of Camooweal, near the border of the Northern Territory.

In *South Australia* the numerous caves have received little attention, except those of Narracoorte, which occur in limestone of Miocene age seven miles south-east of the township and near the Victorian border. They include the Big, Victoria, Bat, Stick, West, Victoria, and Alexandra caves.

In *Western Australia* a gneissic granite range occupies an area in the south-western corner running 60 miles south from Cape Naturaliste. On the irregular seaward slopes of this range drift-sand and shells, including myriads of microscopic foraminifera, have been piled up in dunes to a height of 700 feet; the liberation of carbonate of lime from the shell-debris has cemented the loose particles into a calcareous sandstone, and wherever shells were most plentiful, masses of limestone have been formed, through which escaping waters tunnelled their way and formed caves. In this Recent limestone many fossil remains of vertebrates are found, both of existing and extinct species. In the Mammoth cave, 30 miles from Yallingup, the position is complicated by the intermingling of later fauna with an older series originally deposited elsewhere. Numerous bones and teeth have been identified as belonging to the common echidna (*Tachyglossus aculeatus*), extinct echidna (*Tachyglossus oweni*), giant echidna (*Zaglossus hacketti*), extinct Western Australian wombat (*Phascolomys hacketti*), and a kangaroo (*Stenthurus occidentalis*) quite distinct from the eastern Australian form. *Nototherium* is practically abundant, and several extinct kangaroos—*Macropus magister, M. anak, M. titan, Palorchestes crassus* and others not yet identified—also occur. There are 30 known caves, many of which have been made accessible for inspection. From Perth the nearest are in the electrically lighted Yallingup group, 20 miles from Busselton and 150 miles from Perth. Fifteen miles farther on is the Margaret River group; the Nindup group is about 30 miles from Yallingup. In the Lake cave of the Nindup group a thin sheet of lime ('the suspended table') 14 feet by 7 feet is held to the roof by glistening columns which emerge from countless delicate pendants, and is reflected in the clear waters of an extensive pool.

In *Tasmania* caves in Silurian limestone are frequent, both in the northern and in the southern districts, but only in the former have they been opened up. They include the Chudleigh caves, the Mole Creek series—Scott's, King Solomon's, Bayard's (Marakoopu), and Baldock's caves, all within easy distance of Mole Creek, 60 miles from Launceston—the Ulverstone caves at Gunn's Plains, 16 miles from Ulverstone, and the Winkleigh caves near Beaconsfield. In some caves (particularly in those at Ida Bay in the Huon district) myriads of glow-worms dot the cavern roofs with sparkling points of light.

Most of the Tasmanian caves are privately owned; those at Wellington in New South Wales are (as has been said above) under the management of the local municipal council; otherwise nearly all the caves in the various States are under government control. Where prepared for inspection, they may be viewed in comfort owing to the construction of well-graded pathways, cement, stone, and iron stairways together with protective wire-netting. Capable guides are employed, and accommodation houses are erected either at, or convenient to, the caves. O.T.

Limpets. See MOLLUSCA.

Lincolnshire, MARQUESS OF. Sir Charles Robert Wynn-Carrington, first marquess of Lincolnshire, third baron (from 1895 first earl) Carrington—born on 16 May 1843 and educated at Eton and Cambridge (B.A., 1863), entered the army and became captain in the Royal Horse Guards and lieutenant-colonel of the militia battalion of the Oxfordshire Light Infantry. From 1865 to 1868 he was member for Wycombe in the house of commons, but in the latter year succeeded his father as baron. Accompanying the then Prince of Wales (afterwards Edward VII) to India in 1875-6 as aide-de-camp, he established a personal friendship with the royal family; this, and his attachment to the liberal party in English politics—which was out of office in 1886-92 and 1895-1905—

account for his later career. From 1881 to 1885 he was captain of the corps of gentlemen-at-arms; in 1885-90 he was governor of New South Wales, in which position he entertained lavishly and set an example that his successors found it difficult to follow; in 1892 he became simultaneously lord chamberlain to Queen Victoria's household and a 'progressive' member of the London county council; in 1895 he was created earl Carrington and viscount Wendover. On the return of the liberal party to power in 1905 he was appointed president of the board of agriculture (1905-11), and afterwards lord privy seal (1911-12); he then retired from active public life with the dignity of marquess of Lincolnshire.

His surname has been a puzzle to journalists for many years. That of his grandfather, the first baron Carrington, was Smith. The second baron in 1839 altered it by royal licence to Carington, and this was confirmed to the third baron in 1880. But in 1896 he changed it again, also by royal licence, to Wynn-Carrington. See Round's *Peerage and Pedigree*. (P.C., 1881; G.C.M.G., 1885; K.G., 1906.)

Ling. See Cod.

Linlithgow, Marquess of. John Adrian Louis Hope (1860-1908), first marquess of Linlithgow, better known to Australians as the earl of Hopetoun, was born at Hopetoun on 25 September 1860 and educated at Eton, succeeded to the earldom in 1873, and spent his adolescence in travel through the East and in America. He took little part in active politics, though he was a minor member of the Salisbury administrations of 1885-6 and 1886-9; in 1887-9 he was high commissioner to the general assembly of the Church of Scotland. In September 1889 he was made governor of Victoria, and officiated during the financial crisis of 1891-3—one result of which was the reduction of his salary from £10,000 to £7000. He made himself very popular (but somewhat incommoded his successors) by unbounded generosity and hospitality, as well as by his genuine interest in racing and hunting. Returning to England in 1895, he was given minor posts in the third Salisbury administration (paymaster-general, 1895-8; lord chamberlain, 1898-1900), and became president of the Institution of Naval Architects. When in 1900 it became necessary to appoint a governor-general for the Commonwealth, Hopetoun's previous popularity and great wealth made the colonial office think him the right man for the place, and on 16 December 1900 he landed at Sydney to take up the position. He figured sumptuously at the inauguration of the Commonwealth on 1 January 1901 and during the visit of the then Duke of York in May and June; but the lavish expenditure which he and those who had appointed him thought necessary was not fully recouped him by parliament, which had fixed his salary at £10,000 and his extra expenditure at another £10,000. Further, his intimation that the salary was insufficient failed to procure an increase; so in May 1902 he resigned, left Australia on 17 July, and returned to England to be made marquess of Linlithgow, and to become after an interval secretary for Scotland in the Balfour administration (3 February to 5 December 1905). Then, the illness from which he had suffered since 1900 increasing on him, he retired into private life and died at Pau in France on 29 February 1908.

He was an ill man throughout his governor-generalship, and no doubt welcomed the early retirement. But the scale on which he felt it fit to keep up his position, both in 1889-95 and 1900-2, was beyond both the wishes of Australians and the competence of many men who would have made excellent colonial governors, and harmed the Commonwealth's reputation—since British officials came to regard Australians as people who demanded wealthy governors and were too mean to pay them adequately. In actual fact, when after Hopetoun's resignation Lord Tennyson took his place and told his ministers that he would spend his salary but not a penny more, they assured him that Australians did not expect anything else; and, when at last that fact was brought home to the colonial office, the selection of governors was made both easier for the British authorities and more satisfactory to Australia. (G.C.M.G., 1889; K.T., G.C.V.O., 1900.)

Lisgar, Baron. Sir John Young (1807-1876), first and only baron Lisgar, was born at Bombay on 31 August 1807, educated at Eton and Corpus Christi College, Oxford (B.A., 1829), and called to the bar at Lincoln's Inn in 1834. From 1831 to 1855 he represented county Cavan in the British parliament, was a lord of the treasury from September 1841 to May 1844, and a secretary to the treasury from that date to July 1846. In 1848 he succeeded to his father's baronetcy. In the Aberdeen ministry of 1852-5 he was chief secretary for Ireland; on 20 March 1855 he was made lord high commissioner of the Ionian Islands, but displeased the populace by his opposition to their wish to be absorbed in Greece, and resigned on 25 January 1859. On 22 March 1861 he was appointed captain-general, governor-in-chief, and vice-admiral of New South Wales and its dependencies. Practically his first official act was to consent to Charles Cowper's proposal for forcing the hand of the legislative council by appointing to it 21 new members (see Cowper, Sir Charles). Regretting this hasty act, he called Wentworth into consultation and made him president of the new council. The passing of the 'free selection before survey' act by the Cowper-Robertson ministry, the introduction of *ad valorem* duties, and the education act passed by Henry Parkes in 1866, are among the notable events of his administration. On 24 December 1867 he left the colony, and on 2 January 1869 was appointed governor-general of Canada. In 1870 he was raised to the peerage as baron Lisgar in recognition of his services. In 1872 he returned to England, and died on 6 October 1876. As governor of New South Wales he distinguished himself by his advocacy of social reforms and his wise guidance of Henry Parkes during that statesman's first administration. (G.C.M.G., 1855; K.C.B., 1859; G.C.B., 1868.)

Lissanthe, a small genus of plants belonging to the family Epacridaceae, endemic in Australia. *L. sapida* (Native Cranberry) has an edible fruit resembling that of the European cranberry in size and colour, but with a much thinner fleshy coating. *L. strigosa* and *L. montana* also have small edible fruit; the berries of the latter are white and transparent.

Literature. Probably everyone who has attempted to discuss the literature of any given country has been perplexed at the outset by the question how much, or how little, may be fairly included under this head. Is the term literature to be restricted to works of pure imagination?

If so, it would tend to exclude historians, philosophers, and biographers, who are nevertheless usually given place in literary histories if they possess any power and grace of style. It is difficult to conceive a history of English literature that should exclude the names of Berkeley, Gibbon, or Macaulay. Perhaps it will be useful in this connection to draw a distinction similar to that used in science, and to speak of 'pure literature' and 'applied literature;' 'pure literature' including all varieties of writing that depend wholly or mainly on imagination, and having poetry, drama, and prose fiction for its main kinds, while 'applied literature' is that in which the imaginative or aesthetic purpose is secondary, and is subordinated to some extraneous end, historical, political, or other. Pure literature is obviously the more important of the two kinds, and the more distinctive of the country which produces it. Indeed, in such a survey as this, applied literature can be only very briefly noticed: and it shall be noticed at once, so that the ground may be cleared for the discussion of the more important kind, and for the general questions connected with it.

It was natural, in a young country of stirring and romantic origins, that attempts should soon be made to record the details of early discovery and development. History has always been a hardy growth in Australia, and some very distinguished Australians have devoted their gifts to telling the story of their country. It has indeed been claimed that Australian literature began in 1819 with Wentworth's *Statistical, Historical, and Political Description of New South Wales*, a work frequently inspired by that passionate hatred of abuses, and that not less passionate nationalism, which were the motive forces of its author's life. Another early historian of New South Wales was John Dunmore Lang, whose narrative (1834: revised and completed, 1875) is written in a strongly partisan spirit. Dr. Lang also wrote voluminously, and as a rule polemically, upon the political questions of his day. Though the most important work of Wentworth and Lang was published in England, both are thoroughly Australian in spirit and outlook. From their time onwards a great deal of Australian history and biography has been written by native-born Australians and by Englishmen domiciled in Australia. The leading general histories are *A History of Australia* by G. W. Rusden (2nd edition, 1897); *A History of the Australasian Colonies* by Edward Jenks (3rd edition, 1912); *A History of Australia* (11th edition, 1925) by Arthur Jose; and *A Short History of Australia* (1916) by Professor Ernest Scott. The last two are written with considerable insight and grace, and are easily the most serviceable works for the student.

Of works dealing with special chapters or individual characters of Australian history only a few can be mentioned here. Into the first class fall *A History of the Colony of Victoria* by Henry Gyles Turner, and *The First Decade of the Australian Commonwealth* by the same author, both written with a strong party bias. Equal bias and greater gusto distinguish *The Making of the Australian Commonwealth* by B. R. Wise. In the second class may be reckoned several excellent biographies of great men; notable among them are those of La Pérouse and Flinders by Ernest Scott, that of Father Therry by E. M. O'Brien, the *Memoir of George Higinbotham* by Professor Edward Morris, and the *Life of Sir George Grey* by Professor G. C. Henderson. The early discovery and subsequent exploration of Australia have their special literature; but no detailed account can here be given of original records (e.g. Flinders's *Voyage to Terra Australis*), or of the narratives of Eyre, Leichhardt, Sturt, Forrest, and other explorers; nor yet of such volumes of research as Ernest Scott's *Terre Napoléon*, dealing with Baudin's French expedition of discovery. Works dealing with the aboriginal races of Australia, such as *Native Tribes of Central Australia* by Sir Baldwin Spencer and F. J. Gillen, and *Native Tribes of South-east Australia* by A. W. Howitt, which rank definitely as literature, are discussed under ABORIGINES.

The legal, sociological, and constitutional writings of Professors Hearne and Harrison Moore and Sir R. R. Garran fall only indirectly under the present heading: but honourable mention must be made of the work done in classical scholarship by Professors Badham, H. A. Strong, T. G. Tucker, and Christopher Brennan; in English scholarship by Professors M. W. MacCallum, John Le Gay Brereton, and W. H. Williams, and by E. H. C. Oliphant; in philosophy by Professors Boyce Gibson, W. Mitchell, and McKellar Stewart; and in literary criticism by Professor Walter Murdoch and A. G. Stephens.

In Australian literature written for its own sake the two outstanding kinds are poetry, lyrical or narrative, and prose fiction. The earliest specimens of Australian poetry are more curious than delightful. There is little worth in the long series of King's Birthday odes by Michael Robinson which began in 1810; in *First Fruits of Australian Poetry* (1819) by Barron Field (friend of Charles Lamb, and judge of the supreme court of New South Wales); or even in *Australasia, an Ode*, by W. C. Wentworth, written in a Cambridge university prize competition, and probably the first poem published by a native-born Australian. Yet interest in poetry was not lacking in the young colony, and the *Wild Notes from the Lyre of a Native Minstrel* by Charles Tompson, junior (Sydney, 1826), which he dedicated to his teacher Henry Fulton (q.v.), are at least more scholarly—in eighteenth century fashion—than much verse published in Australia to-day. The Hawkesbury district, from which Tompson came, must have been a source of inspiration, for the earliest true poet of Australia, Charles Harpur, was born at Windsor on the Hawkesbury in 1817, and lived for the most part in the bush until his death in 1868. His desire for literary fame was eager and constant, and the praise of great poets of the past was his frequent theme: he also made translations from the *Iliad*, and has left a few sonnets, some well-turned. His best, and best-known, poem is 'The Creek of the Four Graves,' which describes an episode of adventure in the bush and so anticipates much of the later verse-product of Australia. Harpur was a lonely singer, and had neither local tradition nor environment to help him. A sweeter voice was that of Henry Kendall (1841-1882), who like Harpur was bush-bred, but spent many of his later years in Sydney and Melbourne. His work is dealt with in detail under his name: here we are concerned mainly with its quality and inspiration. From his youth onwards Kendall maintained a deep and sensitive love for the bush, which appears constantly in his poetry, and helps to give their distinctive beauty to such poems as 'Mooni,' 'The Hut by the Black Swamp,' and 'September in Australia.' He was not a profound or original thinker, nor on the other hand had he watched nature with the

close scrutiny of a Wordsworth: but he had a true and delicate gift of song, and fine emotional sensibility. Perhaps the finest and most moving poem he ever wrote is 'Araluen,' a lament for the death of his infant daughter. Many critics still regard him as the truest poet Australia has yet produced.

If Kendall is the first notable lyrist of the Australian bush, Adam Lindsay Gordon is its first notable ballad-maker. His romantic, daredevil and, withal, melancholy personality, and his preoccupation with adventure and sport, have impressed themselves indelibly on the imagination of Australians: and his spirited and adventurous verse has touched, and will always touch, a responsive chord in their hearts. His best and most individual—though not his most pretentious—work belongs to the class of which 'The Sick Stockrider' and 'Wolf and Hound' are the most famous examples. His 'Romance of Britomarte,' set in the Cavalier period, is a very spirited and well-written ballad. But much of his reflective and dramatic poetry is derivative and inferior, and, despite his vogue in Australia, there is little force in the claim made for him to the title of Australia's national poet. Keenly interested in her life, he was at the same time but a sojourner and an alien within her borders, and only in a very small degree did he help to mould or interpret her national character.

A notable poet who belongs to what may be called the period of transition is Brunton Stephens, who left Scotland and settled in Queensland in 1866. In 1871 he published a long narrative poem, *Convict Once*, which, despite obvious defects, displays a psychological insight all too rare in Australian poetry. In 'The Dominion of Australia' Stephens has left one of the finest patriotic poems ever written in this country. He wrote much miscellaneous verse: his best essay in the comic is 'My Chinee Cook.'

The poetry of Australia, up to the stage now reached, had few characteristics (apart from those of subject) which might differentiate it from verse written in other English-speaking countries. Many of her poets had looked upon her merely with the eyes of interested sojourners in the land: a few had even regarded her as a place of exile. But through the vision and enterprise of J. F. Archibald, the founder (in 1881) of the Sydney *Bulletin*, an opening was provided for men who wished to write of Australia as Australians, and to reveal her spirit and atmosphere through the medium of verse or prose. The influence of the *Bulletin* affected many who never contributed to its pages. Men began to write of Australia no longer as a land of exile, but as their own country, to the making of whose destiny they were eager to contribute. The *Bulletin*, though striving ever toward a fuller nationalism, set its face against sentimentalism, and did not insist that its poets should plaster their pages with local colour, or with indiscriminate praise of their country. Two early writers for the *Bulletin* illustrate the different forms in which the new spirit might find expression. Truly Australian in outlook is Barcroft Boake (1866-92), a poet who, like Gordon, led an adventurous life, and, like Gordon, died by his own hand. Boake's work is uneven, even beyond the wont of Australian poets: but his best verse has a sinister power and an individual rhythm. He, too, responded, though less tenderly than Kendall, to the spell of the Australian bush, of which he has left an impressive picture in the opening of 'A Vision Out West.' It has been contended that the melancholy common to the verse of Kendall, Boake, and other Australian poets is the mere result of a literary convention originally set by Gordon's life and writings, and of his self-inflicted death; but the cause lies far deeper than this. Melancholy is a thing not manufactured out of literature, but springing directly from nature and life.

The most distinctive verse of Victor James Daley (1858-1905), on the other hand, has a glamour that owes little to the scenery or the life of his adopted country, but appears rather as an emanation from that Celtic wonderland that was Daley's true home. His best verse, collected in *At Dawn and Dusk* (1898) and *Wine and Roses* (1911), has peculiar grace and distinction and sometimes achieves an almost Heinesque quality. In sharp contrast with him stand two other poets, Andrew Barton Paterson and Henry Lawson, born respectively in 1864 and 1867. These two are the most widely read of recent Australian poets. Their best work is easy, vigorous, and racy of the bush. Paterson's verse at its strongest is capital band-music. Lawson's has greater intensity, vision, and idea, though his fullest strength has probably been reached not in poetry but in prose. A finer singing quality, with less strength, may be found in the best verse of W. H. Ogilvie, a Scotsman whose temporary sojourn in Australia produced several good ballads and charming lyrics. His 'Bowmont Water' is the best poem of exile ever written in Australia.

Australian after a more austere fashion is Bernard O'Dowd. He is the most intellectual of all Australian poets, and the symbolic revaluations of life which he has embodied in *The Silent Land* (1906), *Dominions of the Boundary* (1907), and *The Seven Deadly Sins* (1909) are always interesting, and not infrequently profound and beautiful. In his long poem, *The Bush* (1912), he expresses eloquently his aspirations for the future of Australia. Many of his admirers must have wished that he would more often exchange the hair shirt of the anchorite for the singing robes of the true poet whom they know him to be at heart. But his strong sincerity, loftiness of aim, and powerful and original imagination should win him honour from every true Australian.

John Farrell (1851-1904) who wrote extensively in the *Bulletin* and published a collection of verse, *How He Died*, in 1887, often showed true power, and in *Australia to England* gave fine expression to his country's national sentiment. A more delicate poetic gift was that of George Essex Evans (1863-1909), who has left verse of beauty and distinction, often inspired by his keen sense of Australia's natural loveliness. The veteran George Gordon McCrae, who was a fellow-contributor with Lindsay Gordon to the *Colonial Monthly*, and published his last volume of verse in 1915, wrote in his earlier days two poems (*The Story of Balladeadro* and *Mamba*) founded on aboriginal legends. His son, Hugh McCrae, is among the first of living Australian poets: his verse displays an elvish imagination, and has a fine singing quality. High place must also be given to Arthur H. Adams, whose earlier verse has force, precision, and beauty. Delicacy, subtle colour, and Celtic glamour distinguish the poetry of Roderic Quinn, who has attained his highest power in short poems, such as 'The Lotus Flower' and 'The Seeker.' E. J. Brady has given us some admirable ballads and chanteys: his most notable volume of verse is *The Ways of Many Waters*.

Several good chanteys have also been written by C. H. Souter, who has a happy knack of both light and serious verse. Edward Dyson's ballads of mining life have much raciness and power. The Elizabethanism of John Le Gay Brereton is reflected in his lyrics and sonnets, which have something of the grace and spontaneity of the 'Great Age.' The fine and individual poems of Christopher Brennan suggest the influence of the French symbolists, in whose work this most learned writer has steeped himself. Delicacy, distinction, and a certain wistful beauty are present in the verse of James Hebblethwaite. F. S. Williamson, though his verse is most uneven, possesses at his best as true a singing quality as does any Australian. C. J. Dennis occupies a place apart in Australian poetry. His best-known work, *The Sentimental Bloke*, is racy and amusing, and has had an immense vogue. He uses slang with piquant effect, and offers a quaint yet authentic presentation of certain aspects of Australian character. A more tragic interpretation of Australian life, in bush and city, may be found in the verse of Louis Esson, who has also written some delightful songs. *An Irish Heart*, by David McKee Wright, contains charming lyrics and ballads. Many of the lyrics in Shaw Neilson's *Heart of Spring* embody their author's keen delight in nature: the best of them have a delicate and exquisite music. Australia has produced several soldier poets; the most notable is Leon Gellert, some of whose lyrics show great power. The sonnet has been much practised in Australia: among her best sonneteers may be numbered Patrick Moloney, William Gay, John Bernard O'Hara, Arthur Bayldon, Louis Lavater, and Zora Cross. Zora Cross is one of the most recent of Australia's woman-poets, notable among whom are also Marie Pitt, Mary Gilmore, and Dorothea Mackellar; the last-named writer's lyric 'My Country' is typically Australian in sentiment and sympathy.

Of the art of novel-writing there have been many practitioners, but few masters. Three books stand out:—*For the Term of His Natural Life* by Marcus Clarke, published serially in 1870-2 and in book form (much condensed) in 1874; *Geoffry Hamlyn* (1859) by Henry Kingsley: and *Robbery Under Arms* (1888) by 'Rolf Boldrewood.' Marcus Clarke arrived in Australia at the age of 18, included in his much varied career banking, bush life, and journalism, and in the end obtained a position in the Melbourne public library. During the 14 years of his greatest literary activity he produced two novels, 12 plays, and many short stories, besides several pamphlets and much miscellaneous journalism. The novel by which he is remembered proved him a great artist in the sinister. In *Geoffry Hamlyn* we are in another world—one of hope and contentment and adventure. Henry Kingsley (1830-1876) for some part of the five years he spent in Australia was forced to rough it as police-trooper and swagman: but his chief novel reflects, in the main, the happier elements of his sojourn, those connected with his residence on a station in the 'Western District' of Victoria. It deals with the adventures of a gently-born but impoverished Devonian, who seeks to repair his fortunes in the great new land of the South: and it presents pastoral life in Australia during the 'forties' as set in a golden age before the rush for gold. Still another aspect of Australian life is presented in *Robbery Under Arms*. 'Rolf Boldrewood'—Thomas Alexander Browne—had a long, adventurous, and chequered experience of squatting, both in western Victoria and the Riverina: he had to face the enmity of hostile blacks, and of more hostile and devastating droughts: and he had been also brought into touch with mining life as police magistrate and goldfields warden in New South Wales. He put all this experience to use in his many novels, and in *Robbery Under Arms* gave the world the most famous story of bushranging ever written. All good Australians are familiar with the Marstons, with the faithful aboriginal Warrigal, and with that dashing Claude Duval of the south, 'Starlight.' Boldrewood's style has obvious defects, and his interpretation of character is downright rather than subtle; but his best work, as represented in this novel and in *The Squatter's Dream* and *The Miner's Right*, has great gusto and swing, and communicates to its readers its author's delight in spirited adventure. His *Old Melbourne Memories* is an interesting and lively record of life in Victoria during and after the 'forties.'

These three books—Clarke's, Kingsley's, and Browne's—stand in a class apart. Novels and stories enjoying considerable popular vogue have also been written by 'Ada Cambridge' (Mrs. Cross), 'Tasma' (Madame Couvreur), Mrs. Campbell Praed, Ethel Turner, Edward Dyson, 'Steele Rudd' (A. H. Davis), J. H. Abbott, Miles Franklin, and Louis Stone. A truer artist than any of these is Mrs. Aeneas Gunn, whose books—*The Little Black Princess* and *We of the Never-Never*—give a vivid and authentic picture of life in the backblocks of northern Australia. Louis Becke did not come to his own till after he had left Australia, but served his literary apprenticeship with the *Bulletin*, to which some of his most brilliant work was contributed. Two writers of Australian short stories stand out from the rest—Henry Lawson and Barbara Baynton. Lawson, whose most widely-read prose volumes are *While the Billy Boils* and *Joe Wilson and his Mates*, has great dramatic force, great strength and directness of style, and the eye of a true artist for the detail and colour of bush life. Australians are sometimes accused of taking their own literature too seriously, and of praising it too highly: it is therefore gratifying to be able to justify the general admiration felt in Australia for Lawson by the testimony of a distinguished foreign critic, Professor Emile Saillens, who gives him enthusiastic praise. Good European judges, he says, 'have not hesitated to compare Lawson in the short story with Bret Harte, Gorki, or even with our own Maupassant.' The best work of Barbara Baynton is contained in her *Bush Studies*, which reveal the more cruel side of bush life with vivid and relentless power; she has probably as much genius as any living Australian author, and her work deserves a place beside that of Ambrose Bierce.

Australian prose writings are for the most part fiction or what has been already denominated 'applied literature:' but a few works deserve mention that can scarcely be classified under either of those headings. Such are E. J. Banfield's *Confessions of a Beachcomber*, first published in 1908, and C. E. W. Bean's *On the Wool Track* (1910), both steeped in Australian atmosphere, the one picturing the warm tropical comforts of coastal Queensland, the other the harder, drier, heat-constrained life of the interior. Two volumes by E. J. Brady—*River Rovers* and *The King's Caravan*—also depict well the colour and humour and adventure of Australian life by river and road.

Of the many plays written in Australia hardly any rank as literature. The repertory theatre movement, instituted with such fine results in Melbourne and Sydney by Gregan McMahon, and in Adelaide by Bryceson Treharne, has given Australia almost its sole opportunity of seeing the best plays of leading European dramatists, and has done its best to encourage local talent; so far, however, it has only produced one dramatist of note—Louis Esson, several of whose plays have been produced in Melbourne. In two of his one-act plays, *The Woman Tamer* and *The Sacred Place,* he portrays Australian slum life with realistic strength and skill; in *Dead Timber* he offers a remarkable study of the tragedy and grim humour of Australian bush life. His longer plays are somewhat less successful, but his best work shows him to be a master of situation and dialogue. Among dramatic work published in Australia, a study of Renaissance Italy entitled *A Man of His Time,* by Helen de Guerry Simpson, merits particular notice for its characterization—a quality not common in Australian drama.

It will be seen, then, that out of the always effervescing literary activity of Australians there has emerged a certain amount of really valuable achievement. Bernard O'Dowd claimed a few years ago that, though Australia so far has produced no poet of the first order, she possesses in several individuals the component parts of such a poet. There is nothing in the conditions of her life to forbid such an one arising. On the other hand, higher standards of criticism —especially of self-criticism—and less of mutual admiration are very urgently needed in Australian literature to-day. At present there is charm, and no lack of it, in our native bush-notes wild: but more than charm, and more than mere cleverness, must go to the making of the great Australian poet or playwright who is still to be.

A. T. S.

Lithgow, WILLIAM (1784-1864), was born in Scotland and educated for the church, matriculated at the university of Edinburgh and became a licentiate of the Church of Scotland. As tutor to the family of commissary-general Allan he went to Heligoland, where Allan procured for him an office in the commissariat department; in 1811 he was promoted to Mauritius, and in 1820 to New South Wales as assistant commissary-general. In addition to his commissariat duties Brisbane in November 1824 appointed him auditor-general of colonial accounts, and he was private secretary to Darling during much of that governor's term, as well as clerk of the executive council during the absence of Colonel Dumaresq, and a commissioner of the clergy and school lands corporation. Darling in 1826 made him a director of the Bank of New South Wales, and Bathurst, in disallowing the appointment, suggested that he be made official inspector with control over the directors. As auditor-general he was appointed an ex-officio member of the legislative council in January 1829, and held the office until January 1843; between 1843 and 1852 he was three times renominated to the new council, and finally left politics in February 1856, when that council ceased to exist on the introduction of responsible government. In 1852 he retired from the auditor-generalship with a pension, and died on 11 June 1864, leaving £1000 to the university of Sydney for a scholarship.

Litsea, a genus of the family Lauraceae, consisting of trees, largely represented in tropical Asia. Six species are indigenous to Australia. *L. reticulata* (Bolly Gum) is a coastal-brush tree of 60-80 feet with a diameter of 2-3 feet; it ranges from the Hawkesbury River in New South Wales to Rockingham Bay in Queensland. It is a handsome shade tree, and produces a useful timber known commercially as bolly gum (this trade-name is, however, used for the timber of several species of *Litsea*). *L. dealbata* (Pigeon-berry) in favourable situations reaches a height of 60 feet; its leaves are pale underneath, with prominent veins, and are frequently found in the playgrounds of the tooth-billed bower-bird. The fruit is reddish-purple, and has an aromatic odour.

Liver-flukes, vernacular name of the class Trematoda of the phylum Platyhelminthes, for which see FLAT-WORMS. They are in shape somewhat like Turbellaria, but have no external cilia. They exist as parasites (external and internal) of vertebrate animals, a few being found in invertebrates, and are provided with one or more suckers by means of which they can attach themselves to their host. They have, for the most part, complex life-histories, requiring the participation of an intermediate host, for a type of which the history of the liver-fluke of sheep will serve.

The adult Liver-fluke (*Fasciola hepatica*) is found in the larger bile-ducts of the livers of sheep fed in damp pastures. It is a flattened, leaf-like animal, upwards of an inch in length, with a triangular head-lobe and two suckers at the broader (anterior) end. It is hermaphrodite and self-fertilized; the eggs, which are produced in enormous numbers, pass by means of the common bile-duct into the alimentary canal of the host, and out with the faeces. Only those eggs which fall into water undergo further development. From these a minute ciliated larva hatches out, swims about freely for a while, then burrows into a pond-snail, and enlarges into a cyst. From the internal wall of this cyst other stages are budded off, which differ according to season. In winter the buds become cysts, which enlarge by the destruction of the mother-cyst, and may continue to proliferate several generations of cysts. In summer bodies known as rediae develop within each cyst, which give rise internally to larva flukes (cercariae), differing from the adult in possessing a motile tail. These cercariae break out from the tissues of the pond-snail, live a free life for a longer or shorter time, and then encyst upon grass bordering the water. When grass bearing such cysts is taken into the stomach of the sheep, the cyst-wall is dissolved, and the young fluke, making its way up the bile-duct to the liver, grows to the adult form. It will be noted that a single egg may, if conditions be favourable, give rise to several hundred flukes by proliferation in the cystic stages. When infection is heavy, the flukes cause a condition known as liver-rot. As the life-history of the parasite demands the presence of standing water and pond-snails, fluke usually occurs only in marshy pastures.

A peculiar group of ectoparasitic trematodes, belonging to the genus *Temnocephala* and its allies, occurs commonly on the surface of Australian freshwater crayfishes, and has been monographed by Haswell (*Macleay Memorial Volume,* Linnean Society of New South Wales). These are somewhat leech-like creatures, with a large sucker at the posterior end; the anterior end is split into five or six finger-like lobes, which are adhesive, and enable the animal to loop along the surface of the host. Trematodes occur in

all classes of vertebrates. The Australian species, other than Temnocephaleae, have been described by S. J. Johnston, W. Nicholl, Harvey Johnston, and O. Tiegs, the first-named dealing particularly with those of frogs, birds, and mammals, and the last-named two authors especially with those of fish.

Liversidge, ARCHIBALD, born at Turnham Green near London on 17 November 1847 and educated at the Royal College of Chemistry (exhibitioner, 1867), Royal School of Mines (medallist, and associate in metallurgy and mining, 1870), and Christ's College, Cambridge, was in 1872 appointed first reader in and then professor of geology and mineralogy in the university of Sydney. In 1881 his chair was renamed of chemistry and mineralogy, and in 1891 became one of chemistry only. From 1879 (when the faculty was first constituted) to 1904 he was dean of the faculty of science, and in 1890 founded the school of mines. But his work at the university, valuable as it was, constitutes a small part of his value to New South Wales. He was essentially an organizer of scientific affairs and material. His enduring monument is the Australasian Association for the Advancement of Science, which he founded in 1885, acting as its honorary secretary from 1888 to 1909; from 1875 to 1889 he was honorary secretary to the Royal Society of New South Wales and editor of its journal; he was a member of the first local board of technical education, a trustee of the Australian Museum (1874-1908), and first chairman of the Sydney branch of the Society of Chemical Industry (1903-5). For his untiring work in these directions Cambridge gave him its M.A. degree, Glasgow its LL.D., and the Royal Society of London a fellowship (1882), and he is a fellow of many other learned societies. His only published book is *The Minerals of New South Wales* (1876-82-88), but he has also published many papers on mineralogy and kindred subjects. In 1907 he resigned his chair, and now lives in retirement at Kingston-on-Thames.

Liverworts, vernacular name of a class (Hepaticae) of green flowerless plants, classed with the mosses (q.v.) as bryophytes, which are exceptionally numerous in Australia and Tasmania. Like mosses, liverworts are characterized by alternation of generations, and the plant-body bears the sexual organs; but only the foliose hepatics are liable to be confused with mosses, and the following general points of difference may be noted. (*a*) In hepatics the leaves are usually in two rows, are often bilobed, lack a midrib, and consist of a single layer of cells—whereas the leaves of mosses seldom occur in two rows, and are very rarely bilobed. (*b*) In hepatics the capsule remains within the calyptra until the spores are ripe, and splits longitudinally into (usually) four valves, which are free at the apex; spiral threads (elaters) are generally mixed with the spores; there is no operculum and no columella (except in one family, the Anthocerotaceae), and the seta, or pedicel, is hyaline and fragile.

It is useful to distinguish between hepatics in which the plant-body is a flat thallus, and

Liverworts. (1) *Aneura pinguis.* (2) *Anthoceros punctatus.* (3) *Lejeunea mimosa.* (4) *Jungermannia monodon.*

those in which it is a stem with leaves, after the manner of the mosses. But this distinction can hardly be made a basis of exact classification, because of overlapping forms. The accepted arrangement provides three orders, Marchantiales, Jungermanniales and Anthocerotales.

Marchantiales, of which many species are found in Australia, are all thallose, the thallus consisting of several layers of complex tissues; the sexual organs are usually borne in a more or less umbrella-like receptacle on a long stalk. There are two families, the Ricciaceae and the Marchantiaceae. In the former the sexual organs are immersed singly in cavities of the dorsal surface. We have several interesting species of the genus *Riccia*. The Marchantiaceae are characterized mainly by the stalked umbrella-like receptacle referred to above. The chief Australian genera are *Fimbriaria* and *Marchantia*.

In Jungermanniales (which include most Hepaticae) the plant-body is sometimes a thallus without distinct layers of tissue, sometimes a cylindrical leafy stem. To the former belong the genera *Aneura, Metzgeria, Pallavicinia,* and *Fossombronia,* all occurring in Australia. *Metzgeria* species are of delicate and beautiful structure. To the leafy plants belong numerous genera, of which the most frequently seen are *Trichocolea, Lepidozia, Radula, Frullania, Madotheca, Isotachis, Cheiloscyphus, Cephalozia, Lophocolea, Zoöpsis* and *Plagiochilus. Lepidozia* is often very beautiful in leaf-texture, and *Frullania* and *Madotheca* in their open capsules. Dr. Stephani subdivides the old genus *Lejeunea* into a number of separate genera well represented in Australia.

Anthocerotales represent the highest development among hepatics; they possess a columella, and so approach the mosses. The plant-body is a thallus. The mature capsule dehisces down-

wards by two valves. The single genus (*Anthoceros*) includes several species.

See J. D. Hooker's *Flora Antarctica* (1844-7) and *Flora Tasmaniae* (1860); the *Synopsis Hepaticarum* of Gottsche, Lindenberg and Nees (1844); Franz Stephani's *Species Hepaticarum* (1900 onwards); and articles by F. M. Bailey, R. A. Bastow, Carrington and Pearson, F. von Mueller, L. Rodway, W. W. Watts and T. Whitelegge in the *Proceedings* of the Royal and Linnean Societies of New South Wales and in other scientific journals.

Lizards, vernacular name of the order Lacertilia, the largest group of reptiles to be found in Australia. Lizards may be generally distinguished from snakes by their possessing limbs. Two families, however, contain snake-like reptiles, some species of which have lost all signs of external limbs. Unlike snakes, adult lizards have the two halves of the lower jawbone more or less firmly united in front; most, moreover, have movable eyelids, and a visible organ of hearing that appears externally as a tympanum. They range in size from the tiny skinks, found in the grass or on timber, to the monitors or so-called 'goannas,' the largest Australian species of which reach seven feet in length. Although a few are semi-aquatic, most are adapted to land life. The body is invariably covered with scales. Paired copulatory organs (hemipenes) are present, but these are normally retracted in pockets in the cloaca. Most species lay eggs; but there are many exceptions, and in some the young are born almost as soon as the eggs are laid. The small oval eggs of the common skink are often found amongst rubbish in gardens. Sometimes these are so mature that, when the eggs are purposely broken, the young ones will immediately wriggle out and run away, apparently quite prepared to start life on their own account.

Lizards have a curious organ, situated on the top of the head, which is a very degenerate third eye—the pineal eye. It may often be detected externally, and in the shingle-back skink and goannas appears as a transparent scale, below which the bone is perforated to the brain. In a remarkable New Zealand reptile, the tuatara, this third eye is not so degenerate; and the ancestors of these reptiles, in common with many fossil forms, probably had a functioning third eye.

In the belly, near the hind-limbs, there are present in many lizards the so-called 'fat-bodies;' these in the goanna attain a large size, and are considered by some people to possess medicinal properties. No Australian lizard is venomous, but many are armed with sharp teeth set in strong jaws; as they feed on decaying material, a bite may convey poison to the blood of the victim. The great majority, however, are harmless, and useful as insect destroyers.

Australia has more than 200 species of lizards, included in five families: the geckos (Geckonidae), the snake-like pygopodes (Pygopodidae), the dragon-lizards (Agamidae), the monitors or goannas (Varanidae) and the skinks (Scincidae). No chameleons are indigenous to Australia; a few have been introduced as pets from South Africa.

Geckos are represented by about 50 species. In a typical species the body-scales are soft, often accompanied by granular tubercles. The toes of many terminate in adhesive disks, by the use of which they can walk up walls and windows, and even run across the ceiling; these disks are soft and elastic, and adherence is gained by pressing out the air and forming vacua, not by stickiness. The eyes are covered with transparent skin, the true lids being rudimentary. A healthy specimen will shed its outer skin in a complete slough periodically. Most species have a soft, 'clicky' voice: the word 'gecko' is an attempt to represent the sound made by a common species. The tongue is fleshy, and slightly divided in front; the tail is often curiously shaped, and usually very brittle. When a bird or snake attacks a gecko, it often seizes the prominent tail, which falls off and wriggles, thus attracting the pursuer, whilst the lizard runs away. In a few months a new tail is grown, usually quite unlike the original. A brittle tail is thus a distinct advantage. Most geckos are nocturnal, and devour large quantities of insects. In country districts they make themselves at home in dwellings.

In the Barking Lizard (*Nephrurus asper*) the tail ends in a ball. This gecko has a big head, large eyes, a rough skin with pointed tubercles, and long, angular legs, and is about five inches long; it has the habit of raising itself to the full stretch of its legs, and then lowering the body nearly to the ground; this is done repeatedly. When disturbed, it often gives a short

Barking Lizard.

side-spring and emits a cough-like bark, from which its name is derived. Its bite is not harmful. In captivity it feeds on small grasshoppers and other insects. Specimens are occasionally found in northern Queensland and central Australia, whilst a species with a smoother skin has also been described. In the Leaf-tailed Gecko (*Gymnodactylus platurus*), a larger species found in New South Wales and Queensland, the tail is flattened. A closely-allied form with markedly protective colouring resembles the lichen-covered bark of a tree. These have no adhesive disks to their digits. Some are very handsome, *G. miliusii* being chestnut-brown above, with white cross-bands. Because of their grotesque appearance certain geckos, though harmless, have been given the inappropriate name of 'wood adder.' The genus *Diplodactylus* contains no less than 20 species; a familiar one (*D. vittatus*) is sometimes, from the pattern on its back, called the carpet gecko. The Ribbon-tailed Gecko (*G. taenicauda*) has a curious streak of tawny colour on the tail. Several species of *Oedura* are commonly found under the loose bark of trees. *O. tryoni* is a handsome species with ocellated spots on the back.

In several respects our most interesting family is the Pygopodidae, confined to Australia and

LIZARDS, SNAKES, AND FROGS

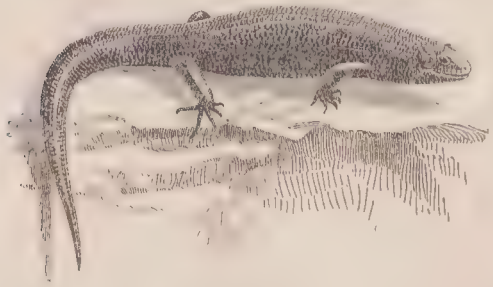
7. Black Snake (*Pseudechis porphyriacus*).

used to pick them up. The Water Dragon (*Physignathus lesueuri*), a large lizard, is occasionally found near water in the eastern States; it grows to over three feet in length, and is possibly the reason why 'young crocodiles' have been allegedly seen in the southern parts of Australia. Several large, compressed scales form a crest along the upper neck, which is continuous with a smaller series that crests the body.

The Varanidae (monitor lizards) are in Australia popularly called goannas: this word is a corruption of 'iguana,' but—since the true iguanas are not found in Australia—has been adopted as an independent name for Australian monitors. The skin of these lizards is covered



Land Mullet.

with small scales and tubercles; the tongue is very long, divided in front, and can be put forth for a considerable distance as an organ of investigation; the teeth are sharp, and are attached to the inner side of the jawbones. Fingers and toes are armed with sharp claws, useful in climbing. A common species is the Tree Goanna or Lace Monitor (*Varanus varius*), which grows to at least six feet, and is a great climber. Its prevailing colours are black and yellow; it may be readily distinguished from *V. gouldii* (which is more characteristically a ground form) by the presence of alternating black-and-yellowish bands on the tail. These goannas are great robbers and scavengers, devouring any dead or living animals they can secure, and are very fond of birds' eggs, including those of the domestic fowl. A specimen of *V. varius* in the Queensland Museum was found with a native porcupine partly swallowed. Goannas lay about a dozen eggs with tough shells, of oval shape and above two inches in length. Fourteen species have been described.

The skink family (Scincidae) is by far the largest family, and includes a variety of forms, from little lizards that run in the grass and on fences to species of *Egernia* which are fully two feet long. Most have well-developed limbs, and are clothed with smooth scales, but a few are prickly and spinous. The giant of the family is *E. bungana* (sometimes called Land Mullet), a shining black skink which grows to over two feet and is found in the mountain scrubs of eastern Australia. After wet weather it may be seen lying out in the sun on logs. There are about 10 other species, of which two from the western and central regions have spiny tails. *E. cunninghamii*, not uncommon about Melbourne and Sydney, is a prickly species about a foot long. The blue-tongue lizards are clumsy, smooth-scaled skinks with short limbs and a bluntly triangular head. They have been mistaken for death adders by careless observers. The commonest, *Tiliqua scincoides*, grows to about 18 inches. In captivity this will feed on raw meat, and is known to eat fungi. The blue-tongue lizard and some species of *Egernia* will emit violent blasts of breath when disturbed, this being caused by a muscular, bellows-like movement of the body. An allied skink, *Hemisphaeriodon gerrardi*, has a long tail which is somewhat prehensile—a very unusual characteristic of this family. The Shingle-back or Double-headed Lizard (*Trachysaurus rugosus*), considered our ugliest lizard, grows to about 15 inches, and is very sluggish. The tail is short, broad, and almost as large as the head. The scales on the back are large and thick: as they overlap considerably, the name 'shingle-back' is appropriate. The lizard is in reality armour-plated, as each thick scale hides a bony plate. Specimens are often infested with ticks (not cattle-ticks). In captivity the shingle-back will eat raw meat, which at first it investigates with its dark purple tongue. The young are brought forth alive, and are of astonishing size, being nearly half as big as the mother. The genus *Lygosoma* contains a large number of skinks, greatly varying in size and structure. Some of the smaller forms have on the lower eyelid a transparent space which forms a little window. These lizards can thus close their eyelids and still look out. In this genus we get all stages of limbs, from lizards with well-developed legs, each supplied with five

Blue-tongue Lizard.

Lygosoma punctatovittalum

toes, to worm-like or snake-like reptiles in which all external signs of limbs have disappeared (*L. ophioscincus*). The number of toes is variable, some species having tiny stumps with no digits. In several there is no external sign of an ear. One of the commonest, *L. verreauxi*, grows to over a foot; on the small forelimb there are three small divisions or toes, whilst the still smaller hind-limb is a simple stump. This lizard is often found under logs, and is dark-brown above with a white band at the back of the head. Another, *L. punctatovittatum*, is illustrated here. The majority of skinks are brown, with a brilliant sheen in sunlight, and often have an elegant pattern of darker markings. One of the largest is *L. lesueuri*, a handsome lizard with white-edged black bands along the back and upper parts of the sides, and with white spots. It grows to nearly a foot, and is very swift. Some skinks have fragile tails, which grow again if partly broken, and form a bifurcated or so-called double tail; more rarely specimens are seen with three divisions to the tail. Skinks of the genus *Ablepharus* have a transparent disk covering the eye. *A. boutoni* is a very common, agile lizard, marked along the body with black-and-white bands which have gained for it the name 'railway lizard.' It is found on fences, where it preys on flies. H.A.L.

Lobster. See CRAYFISHES.

Local Government. In every State of the Commonwealth a system of local government is in operation. Generally speaking, local authorities exercise their powers under (*a*) constituent acts by which they are created and empowered to carry out necessary functions, and (*b*) general acts, each dealing with a single subject or group of subjects, which give them administrative authority for the purpose of such acts. But in Australia general acts are usually administered directly by local officers of the central government, e.g. those relating to education, police, etc. The system of local government in operation here, as in England, is based on the principle of a grant of specific powers by the State legislatures to the local authorities; their autonomy is, however, more or less limited by the provision which is made for general supervision by a department of the central government or by the governor-in-council. Otherwise, within the scope of the acts under which they are constituted or which they have to administer, they are responsible only to the ratepayers. The cities of Sydney, Melbourne, Geelong, Hobart, and Launceston, incorporated under separate acts, stand outside the general scheme. The powers and responsibilities of local bodies are in general similar in all the States, and cover such matters as the upkeep and construction of roads and bridges (see ROADS AND BRIDGES), water and sanitary services except in the chief cities (see WATER SUPPLY AND SEWERAGE), lighting, and the administration of the dog acts, food and drugs acts, slaughtering acts, weights and measures acts, width of tires acts and similar measures. There are also a number of functions which local authorities may perform, either with or without the consent of the ratepayers or the governor-in-council; e.g. they may establish hospitals, recreation grounds, libraries, museums, and transport facilities, provide asylums, and support charitable institutions; they may also obtain additional powers for special undertakings by means of special acts. As regards the election of officers, methods of valuation and rating powers, the systems differ considerably in the several States. A system of local government was in operation in Western Australia in 1838, though not on an elective basis; the first elective body in Australia was the municipality of Adelaide, which was incorporated in 1840.

New South Wales.—The first act which provided for any degree of local government on an elective basis was the parish roads act of 1840, under the provisions of which one-third of the proprietors of lands through which, or within three miles of which, a parish road passed, could requisition the magistrates in petty session for authority to elect trustees who were empowered to levy a rate not exceeding 6d. per acre, to buy, sell, or exchange lands, to appoint surveyors, to establish toll-bars and tolls, and let them on lease for a period not exceeding one year, and to borrow money for the purposes of road-making and repairing. During 1842, by the Imperial act for the government of New South Wales and Van Diemen's Land (see CONSTITUTIONS), the governor was empowered to constitute district councils with local functions, the revenue for which was to be raised by rates levied within each district. The qualifications for councillors and electors were respectively the same as those for members and electors of the legislative council. The duties of these councils covered the construction and upkeep of roads, streets, bridges, and public buildings; the establishment and support of schools; the making of orders-in-council; the purchase, sale, and management of property; the provision of means for defraying such expenses connected with the administration of justice and police within the districts as were by law directed to be defrayed by the district. But this comprehensive scheme of local government was strongly opposed in the colony because it involved payment by the proposed councils of half the police expenses, though the governor retained full control of the police force; it was therefore only partially enforced. Under its provisions Appin, Campbelltown, Camden, Narellan, and Picton were in 1843 incorporated under one district council, Appin and Campbelltown being later constituted separate districts, and by 1844 there were eight district councils in New South Wales; but, with the exception of certain road-trusts especially established, no further extension of the principle of local government took place in that colony until 1858, when the municipalities act was passed. It provided for the incorporation of any town or rural district as a municipality upon petition from 50 resident householders, unless a stronger counter-petition were made. Every ratepayer was eligible as elector or councillor. The municipal revenue was derived from tolls, from a general rate not exceeding 1s. in the £ on the assessed annual value, and from special rates for sewerage, etc. Provision was also made for a government subsidy for 15 years after incorporation. Under the act 35 districts were incorporated, and of these 33 still exist. An act of 1867 repealed the act of 1858 and provided for the classification of all future municipalities into boroughs or municipal districts; existing municipalities were classified as boroughs. Any city, town, or suburb of the metropolis, or of any populous country district, might be constituted a borough if it had a population of not less than 1000 and an area of not more than nine square miles, of which no part was more than six miles distant from any other part; any part of the country not containing a borough, and having

an area of not more than 50 square miles and a population of not less than 500, might be constituted a municipal district. Incorporation was on a voluntary basis. Plural voting for aldermen was allowed. This act with its successive amendments was consolidated in 1897, but no new principle was introduced until the shires act was passed in 1905. The voluntary system—which had been very unsatisfactory, only 2830 square miles being incorporated in 1906 out of a total State area of 310,367 square miles—was abandoned; the State, with the exception of existing municipalities and the western division, was divided into shires, and these subdivided into ridings with equal representation in the shire council, in which wide general powers were vested; the rates, which were to be not less than 1d. nor more than 2d. in the £, were no longer to be charged on the annual rental but on the unimproved value of land, and as soon as they were imposed the operation of the State land tax act ceased. The principles embodied in the shires act were extended to municipalities by the local government extension act of 1906, by which the distinction between boroughs and municipal districts was abolished and the governor empowered to proclaim as a city any municipality which had, during the five years preceding such proclamation, an average population of at least 20,000 and an average revenue of at least £20,000, and which formed an independent centre of population. A local government act of 1906, consolidating the acts governing shires and municipalities, came into operation on 1 January 1907; it was amended in 1907 and 1908, and was repealed by the local government act of 1919, which continued and improved the system adopted in 1906. Provision was made for the continuation of existing shires and municipalities, for the creation of new ones, and for their reconstruction by uniting, dividing, altering, or converting areas. Provision was also made for the constitution of a larger municipal unit by empowering municipalities or shires to join in creating county districts; four county districts (St. George, Richmond River, Clarence River, and Southern Riverina) have since been formed by municipal and shire councils co-operating for specific purposes. It was also deemed advisable to provide for municipal units smaller than the shires, and under the act any village or town in a shire may be proclaimed an urban area, with a committee of three members exercising certain powers locally under the supervision of the shire council. There are 75 urban areas now in existence.

Under the act each shire is divided into three ridings, and each municipality may be divided into wards by petition of the council (or a majority of the ratepayers) to the governor. A shire council consists of either six or nine councillors (presided over by a president), and a municipal council of six to twelve aldermen (presided over by a mayor) with certain exceptions. The election of councillors takes place simultaneously throughout the State every three years. All adult owners or rent-paying occupiers of rateable property of a minimum annual value of £5, who are either natural-born or naturalized British subjects, are entitled to the municipal franchise, and any person so enrolled (unless otherwise ineligible) is qualified for election as councillor or alderman; women were made eligible by the women's legal status act of 1918. The local authorities are empowered to construct and maintain roads and streets, to provide a public water-supply and sewerage or sanitation system, to supervise the public health and enforce the public health acts, to carry out town improvement schemes, to regulate the erection of buildings, to provide and maintain public reserves, parks, baths, libraries, hospitals, etc., to manufacture and supply gas, electrical or hydraulic power, to provide telephone services for outlying districts, to acquire and preserve places of historic interest or scenic attraction, to control the plucking of wild flowers, to keep rivers and watercourses free from obstruction, to impound straying animals, to regulate burials and cremations and provide cemeteries and crematories, to establish public markets, weighbridges, wharves, abattoirs, sheepdips, inland watering-places for travelling stock, etc., to regulate the sale of fish and meat, to license vehicles, to build light lines of railway and tramways and maintain ferries, to build and sell houses for working-men, to provide and manage employment registries, to compel the destruction of noxious weeds, etc. The powers of local bodies in the other States correspond on the whole to those exercised in New South Wales, and will not be separately indicated.

All land (except public parks, the sites of charitable institutions, unoccupied crown lands and similar areas) is rateable in New South Wales. Four kinds of rates are levied. In shires a general rate of not less than 1d. nor more than 2d. in the £ is levied on the unimproved capital value of land, power being vested in the governor to sanction a rate of less than 1d. if the proceeds more than suffice to meet the needs of the council. The municipal general rate must be not less than 1d. in the £ and not more than is required to yield a sum not exceeding the amount that would be derived from rates of 2d. in the £ on the unimproved capital value and of 1s. 6d. in the £ on the assessed annual value of all rateable land. Special and local rates may also be levied on either the improved or the unimproved value, but a poll may be demanded by the ratepayers to decide the basis of assessment. If a council proposes to raise a special loan, it must levy a loan rate sufficient to provide a sinking-fund as well as interest; 25 per cent of the ratepayers may demand a poll on the question whether a loan shall be raised and whether the loan rate shall be levied on the unimproved or the improved capital value. The total of all rates must not exceed the amount that would be yielded by rates of 2d. in the £ on the unimproved capital value and of 2s. on the assessed annual value; but this maximum may be exceeded with the special permission of the governor. Profits made on public undertakings must not be used to reduce rates. Government grants may be made to municipalities and shires for specific purposes; in addition a government endowment of not less than £150,000 is distributed annually among the shires, the amount paid to each shire being determined according to the extent of the shire, the necessary expenditure, etc., and paid on the basis of the amount of general rates collected in the preceding year. In 1922 a sum of £156,861 was paid as government endowment. Both shires and municipalities have borrowing powers within a limited range. A uniform system of accounts is prescribed, and all town and shire clerks are required to hold certificates of competency issued by a committee appointed under the local government act. If a local government area defaults under the terms of the act, the governor

is authorized to appoint an administrator for such area. The act is administered by the local government department, which was first constituted as a branch service when the 1906 act was under consideration, and has since been made an independent department with a ministerial head. The autonomy of councils is limited by the authority of the department, which not only acts as an intermediary between the councils and the governor in regard to proposals requiring the governor's assent, recommends the basis of distribution of government subsidies, and finally determines the alteration of boundaries, but also directly supervises local borrowings, inspects the annual balance sheets, and exercises a certain amount of vigilance to see that members do not engage in trade with their own councils; it may also grant or withhold authority to levy rates in excess of the legal maximum, to sell land held by the council, to exercise powers under the native dogs and poisoned baits act of 1901, etc. The department further makes available to councils its expert engineering staff, assists them with advice on town-planning, and collects and collates information.

The city of Sydney was incorporated in 1842. In 1849 a select committee reported that the city council had 'entirely lost the confidence of the citizens, and was regarded as an impediment to the improvement of the city;' it recommended that the corporation be dissolved, and its powers vested in three commissioners. A resolution embodying these recommendations was defeated in the legislative council in 1849; but in 1853 (after further consideration by a select committee in 1852) the corporation was dissolved and three city commissioners were appointed by the governor. In 1857 self-government was restored.

The city is now (1925) divided into 13 wards, each returning two aldermen; the franchise may be exercised by any adult natural-born or naturalized British subject who is (*a*) the owner of freehold property assessed at not less than £5, or of a leasehold of an annual value of £25, or of a house, shop, etc. of the value of £10, (*b*) has been a lodger continuously for six months and occupied lodgings of the value of £10 or upwards. Any enrolled adult is eligible for election as alderman; women are qualified under the women's legal status act of 1918. In 1908 the city council was empowered to assess general rates on the unimproved capital value instead of on the improved value, and under these conditions the levying of the land tax was suspended. The general rate must not be less than 1d. in the £ in addition to any other rate, but the total amount of all rates levied must not exceed 3d. in the £ on the unimproved value, or 2s. in the £ on the average annual value. The city is not subject to the supervision of the local government department.

Under the fire brigades act of 1909 municipalities in New South Wales contribute, equally with the colonial treasurer and the insurance companies, to the expenses of the board of fire commissioners which was then created and given jurisdiction over the eight fire districts into which the State was divided; but expenditure must be so regulated that the proportion payable by the councils in any fire district must not exceed the amount obtainable from a rate of one farthing in the £ on the unimproved capital value of the district. The contribution of the municipalities in 1922 was £53,979.

The total area of the State incorporated at the end of 1922 was 183,985 square miles, 2845 square miles in municipal areas and 181,140 in shires. There were 185 municipalities, with a total population of 1,471,020, an unimproved capital value of £123,823,897 and an improved capital value of £349,902,171; and 136 shires, with a population of 688,560 and an unimproved capital value of £135,380,748.

Victoria.—Until 1850 Victoria then known as the Port Phillip district, was under the jurisdiction of New South Wales, and Melbourne and Geelong were incorporated under special acts of the New South Wales legislative council in 1842 and 1849 respectively. The Imperial act of 1850, which created the colony of Victoria, empowered the governor to proclaim districts under the Imperial act of 1842 upon petition of the inhabitants, and to establish elective district councils with power to make by-laws for constructing and maintaining roads and bridges, establishing schools, and levying local tolls and rates. The clause requiring a district council to provide half the cost of maintaining the police within its district was deleted. But a more comprehensive scheme of local government soon became necessary to meet the needs of a rapidly growing population, and in 1853 there was passed a roads act which (*a*) made provision for the creation of a central road board for the care of main roads, and (*b*) authorized the governor to divide the colony into road districts within which local boards responsible for parish roads and with power to levy local rates might be elected by resident property-holders. This act, which made provision chiefly for local government in country districts, was repealed in 1863, when a road districts and shires act was passed. The central road board was abolished; any road district having an area of not less than 100 square miles and a revenue from general rates of not less than £1000 might be incorporated into a shire, with powers additional to those of the district, including the right to raise loans and grant licences. An act of 1854 had already provided that any district having an area of not more than nine square miles, no part of which was more than six miles distant from any other part, and having a population of not less than 300 persons, could be incorporated into a municipal district or borough. The principal clauses of this act were consolidated (with amendments) in the boroughs statute act of 1869. The provisions of both the shires statute act and the boroughs statute act were consolidated by a local government act of 1874, which after further amendments was itself consolidated by the local government act of 1890. In 1899 a select committee (later constituted a royal commission) was appointed to enquire into the local government system then in operation; to its report, issued in 1902, was attached a draft bill which became the local government act of 1903, consolidated with amendments in 1915. Under this act provision is made for the continuation of municipalities already established and the incorporation of others. Any part of the State returning from rateable property, at a rate not exceeding 1s. in the £, a sum of £1500 may be constituted a shire upon petition of at least 50 inhabitants; any area not exceeding nine square miles and with no point more than six miles distant from any other point, and having a population of not less than 500 resident householders and rateable property yielding from a rate not exceeding 1s. in the £ on annual value a sum of £300, may

be constituted a borough upon petition of at least 250 householders; any area not exceeding three square miles in extent in any shire and distant more than ten miles from the city of Melbourne, may be proclaimed a township upon petition of 25 ratepayers. In municipalities the number of council members is a multiple of three, not less than six nor more than 24; if the area is subdivided, three councillors represent each subdivision. Any male adult holding property of the rateable value of £20, unless otherwise ineligible, may be elected a councillor. The councillors elect their own chairman, who in cities, towns and boroughs is called the mayor and in shires the president. Every adult (except non-naturalized Chinese) with property rated at £5 a year, or on which there is a dwelling-house, may exercise the local franchise providing that rates have been paid three months or more before elections and that the occupier and the owner of any rateable property are not both enfranchised in respect thereof, the former having the prior right to enrolment. Corporations liable to rates may enrol in their stead not more than three persons; joint occupiers and owners not exceeding three are each entitled to enrolment. Plural voting is allowed on a fixed scale. All land (including buildings and improvements thereon) within a local government area is with certain exceptions rateable property, the valuation of property being computed at its net annual value (that is to say, at the rent at which it might reasonably be expected to let from year to year free of all usual tenant's rates, taxes and cost of maintenance), providing that the sum so computed be not less than five per cent upon the fair capital value of the fee-simple. A council may, however, with the consent of the ratepayers—obtained, if required, at a poll—levy rates on the basis of the unimproved capital value of the land, and adopt the valuation made by assessors under the land tax act of 1915. The councils may levy general, extra and special rates. General rates must not exceed 2s. 6d. in the £, nor be less than 6d. in the £, on the net annual value, and must be levied on the occupier of the property rated—or, if there be no occupier, or if the occupier be the Crown or some public authority or body, then upon the owner of the property. Extra and separate rates may also be levied under given conditions. The councils may borrow money to a limited sum. The government endowment to boroughs and shires is based by law on the annual amount of general and extra rates received; no city or town is entitled to such assistance. In 1922-3 government endowment amounted to £50,000, and an extra sum of £64,340 was paid as the equivalent of licence fees, etc., incurred under the licensing act of 1915. The whole State (with the exception of French Island) is now subject to the provisions of the local government act, though the cities of Melbourne and Geelong, incorporated under separate and early acts, are subject to it only in a few details.

Melbourne, incorporated as a town in 1842, was proclaimed a city by letters patent on 25 June 1847, an act to that effect being passed in 1849. The city is now divided into eight wards, each represented by one alderman and three councillors. The lord mayor is elected annually by the councillors and aldermen from among their number, and the councillors (elected for three years) choose aldermen who hold office for six years. Two assessors for each ward and two auditors for the city are elected annually. The qualifications for councillors, assessors and auditors are that they be male adults in possession of real or personal estate to the value of £1000 or assessed in respect of rateable property having an annual value of £50. The franchise may be exercised by adults occupying any house or shop of an annual value of £10, and by resident householders in the city or within seven miles thereof. Plural voting is provided for. Geelong, incorporated as a town in 1849, was proclaimed a city in 1910, the acts passed for Melbourne being made applicable to Geelong. In 1923 there were 53 cities, towns and boroughs and 139 shires incorporated in Victoria. Victoria is divided into a metropolitan fire-district (under a metropolitan fire brigades board) and nine country fire-districts (under a country fire-brigades board). The municipalities are represented on the boards, and contribute to their expenses.

Queensland.—Shortly before the separation of Queensland in 1859, Brisbane was incorporated under the New South Wales municipal corporations act of 1858. In 1864, by a Queensland municipal institutions act, the governor of the new colony was empowered to incorporate as a municipality any city, town or rural district with a population of not less than 250 inhabitants on the petition of at least 100 resident householders. Powers vested in the councils included the construction and maintenance of roads, bridges, ferries, cemeteries, baths, water-supply, lighting and sewerage, and the prevention of the erection of easily inflammable buildings in 'first-class divisions.' The provincial councils act of the same year (1864) empowered the governor, on petition, to proclaim any portion of the colony a province, and to appoint a council of not less than three or more than nine members. Only one council was constituted under the provisions of this act, and it soon collapsed. During the seventies certain road trusts were also established, though without legislative sanction, to effect minor improvements. No new principle was introduced until 1878, when a local government act made provision for the compulsory incorporation of municipalities and for the division of rural areas into shires of the Victorian pattern. But this shire-system was found to be unsuited to the conditions of a sparsely populated country, and in the following year a divisional boards act authorized the governor to constitute any portion of the colony outside existing municipalities a division, with a board of not less than three nor more than nine members. Provision was made for postal voting. The act was applied to about 660,000 square miles of territory, which was cut up into 74 divisions, some of vast extent and very sparsely populated. The new boards were to be subsidized by the government to the amount of 1s. in the £ on the annual value, plus an endowment equal to £2 for every £1 of rates collected for a period of five years and thereafter £ for £. Should a division fail to elect its board, the governor was empowered to nominate members; of the new divisional boards about half were appointed in this way. The divisional system with certain amendments (e.g. in 1890 provision was made for the levying of rates on the unimproved capital value of the land instead of on the annual value) was retained until 1902, when a local authorities act was passed; this act with amendments now constitutes the principal act. Under its provisions the whole State is incorporated into cities, towns, and shires; all municipalities

formerly constituted as boroughs are towns, all shires and divisions are shires. The act declares Brisbane, Rockhampton, and Townsville to be cities and empowers the governor to proclaim other cities—the city of South Brisbane was proclaimed in 1903. The power to alter municipal boundaries lies entirely with the governor-in-council, who may act on his own initiative. Local authorities may constitute joint boards to exercise certain specific powers of the constituent local authorities. Town councils consist of seven, nine or eleven aldermen—or, if the area is divided into wards, of three aldermen from each ward; shire councils consist of five, seven or nine councillors, or, if the shire is subdivided, of not more than three from each division. Members are elected for three years; one councillor from each ward retires annually in a divided area and a fixed proportion of councillors in an area that is not divided. On petition of at least one-fifth of the ratepayers the governor may dissolve the council and order a fresh election. The municipal franchise is extended to all adult natural-born or naturalized British subjects within the jurisdiction of the local authority, plural voting being provided for; with certain exceptions every enfranchised adult, wherever his residence, is qualified for election as alderman or councillor. All land (except unoccupied crown land, land used for public purposes, etc.) is rateable, both general and special rates being levied on the unimproved capital value, which must be determined at least once every three years in a town and once every five years in a shire. The general rate must not exceed 6d. in the £ nor fall below ½d.: special rates must not exceed 3d. in the £—but this provision does not include separate rates, special water rates, loan rates, cleaning rates or tramway rates. The councils are empowered to raise loans; there are practically no government subsidies. The municipalities contribute towards the maintenance of local fire-brigades. The central administrative authority is divided between different departments, the chief being the home secretary's department which administers the constituent acts. Certain powers of supervision and control are reserved to the central departments. In 1922 there were in Queensland 36 cities and towns and 134 shires, the former having a total area of 522 square miles and a population of 343,799 and the latter an area of 669,372 square miles and a population of 427,739. The capital value of the cities and towns was £19,486,391, and of the shires £50,284,568.

In 1924 was passed an act for the good government of the city of Brisbane, which, like other cities of the State, had previously been subject to the provisions of the municipal acts. Provision was made for the creation of a new city area from the amalgamation of the cities of Brisbane and South Brisbane, six towns, 10 full shires and parts of two other shires. The city council consists of 20 aldermen, each representing a different ward, and a mayor chosen by the electors of the city voting as one electorate. The first election was held on 21 February 1925, and the council met on 18 March; but it will not exercise full powers until October 1925, when various boards constituted under the local authorities act, the health act and the electric light and power act will be dissolved.

South Australia.—In this State the settled districts are controlled for purposes of local government by two types of local authorities, which function under separate acts—municipal corporations and district councils. Large areas of the State are still unincorporated. A system of main road boards was established in 1849, but they were abolished in 1887; their powers were vested in the corporations and councils. In the third annual report (1839) of the colonization commissioners for South Australia a recommendation was made that towns with 2000 inhabitants should be given municipal institutions; an ordinance was therefore issued in 1840 for the incorporation of Adelaide. In 1849 a municipal corporations ordinance empowered the governor to incorporate, on petition of not less than two-thirds of the resident householders, any town, village, or hamlet with certain exceptions; but only five municipalities, exclusive of Adelaide, had been constituted when the ordinance was repealed in 1861 by the municipal corporations act. Under this act the governor was empowered, on petition, to proclaim any place a municipality; municipal corporations were authorized to maintain streets, common sewers and water-works, to levy water-rates, to control public slaughter-houses and markets, to contract for cleansing and the removal of night-soil, and to organize fire-brigades, etc. A consolidating act of 1880 was in turn consolidated by the municipal corporations act of 1890, which is still the principal act relating to municipalities, though it has been amended several times. Under its provisions the governor is empowered to constitute new municipalities, or to alter the boundaries of existing ones, on petition of not less than two-fifths of the ratepayers or owners of rateable property concerned, provided that the value of rateable property therein is sufficient to produce at least £300 per annum from the general rate; he may also re-arrange, increase or diminish the number of wards of a municipality on petition of not less than one-fifth of the ratepayers therein. The first district councils act (passed in 1852) empowered the governor on petition to constitute districts; all occupiers, owners and tenants were qualified to vote for a council of five members, who were given control of the roads within the district, and were authorized to license pounds, to issue slaughtering, depasturing and timber licences, and to nominate persons to serve as constables each year. This act with amendments was consolidated by the district councils act of 1858 (which gave additional powers to the councils), but no important alterations were made until 1887. Plural voting was then abolished; drainage boards were merged with the councils, which were also vested with the powers previously exercised by the main roads boards and with other new powers. In 1914 a district councils act repealed all acts relating to district councils; this with amendments is still in force. It provides for the continuation or amalgamation of existing districts and for the incorporation, on petition, of any area not held under pastoral lease, containing rateable property capable of yielding £200 on a rate not exceeding 1s. in the £, providing that the petition be signed by 50 inhabitants—or, if the area concerned comprise part of an existing district, by a majority of the ratepayers, providing that such majority owns or occupies more than half the rateable property. Municipal corporations consist of a mayor for the municipality and of two councillors for each ward therein, elected by qualified voters; on petition of the corporation, confirmed by a poll of ratepayers, the governor may proclaim that the portion of the act relating to aldermen is to be applied, whereupon

aldermen elected by the whole municipality are added to the councillors. District councils consist of five to ten councillors, who elect a chairman from among their number. Every adult ratepayer (women were included in 1914), with certain exceptions, is qualified to be elected either to a municipal or district council; the local franchise may be exercised by every adult ratepayer, but in municipalities aliens may not vote. In municipalities voters have one vote for each ward in which they have property. Rates are levied in municipalities on the rent at which property would let for seven years, with a minimum of 5 per cent of the total value. In districts, all land outside townships and all occupied land or buildings within them are assessed at four-fifths of the gross annual rental at which they would let for seven years or at 5 per cent on the capital value of the fee simple; town lands unbuilt on are rated at 5 per cent of their value, and mining land leased from the crown on a valuation that must not exceed their annual rental. Municipal corporations may declare a general rate not exceeding 1s. 6d. in the £, a lighting rate not exceeding 4d., a rate for the improvement of park-lands, squares and reserves not exceeding 3d., and a fire-brigades rate not exceeding 3d.; a watering rate may also be levied. With the consent of the ratepayers special rates may be levied, providing that the total rate does not exceed 2s. in the £. In districts rates are of five kinds: general, special, separate, differential separate, and watering; the general rate must not be less than 1s. nor more than 2s. in the £ on the assessed annual value. Both municipal and district councils have borrowing powers, and, under the district councils and corporation subsidy act of 1890, are entitled to grants from the general revenue in lieu of fees formerly received under the auctioneers act of 1862 and the licensed victuallers act of 1880 up to a quarter of the sum collected from general rates not exceeding 1s. in the £ declared during any one year. The city of Adelaide was first incorporated in 1840 under a special ordinance, but the council was abolished in 1843; from that date until 1849 the city was managed as a government department, and from 1849 to 1852 by city commissioners. In 1852 a council was again elected under the provisions of the municipal corporations ordinance of 1849. Since the passing of the municipal corporations act of 1881 Adelaide has been subject to the provisions of the acts relating generally to municipal corporations. The city and other metropolitan municipalities are represented on the fire brigades board of South Australia, and contribute to its expenses.

In 1917 a local government department was established to maintain closer relations between the government and the local bodies, to control the grants-in-aid, to advise on road construction and generally to co-ordinate the road work of the department with that of the local authorities. Usually it has no control over local loans; the minister has power, however, to withhold subsidies payable to local authorities if they fail to carry out any duty imposed by legislation. There is no central control of local officers, except officers of health, whose appointment or dismissal is subject to the approval of the central board of health. All works carried out with financial help from the government are inspected by officers of the central department. The accounts of district councils are subject to the inspection of the auditor-general. By-laws must be approved by the governor. The central department has an advisory rather than a controlling authority.

In 1922 there were 35 corporations and 151 district councils in the State, the corporations covering 59,279 acres with a population of 220,559 and a capital value of £51,100,946, and the district councils 30,196,509 acres with a population of 272,104 and a capital value of £68,293,518. The assessment value of the corporations was £2,544,974 and of the district councils £3,429,776.

Western Australia.—Here three distinct local authorities function: municipal councils, district road boards and local boards of health. The municipal system was established in 1838, when towns were placed under the jurisdiction of non-elective trusts consisting of all resident justices of the peace and landowners. In 1851 Perth was made a city, and in 1871 a municipal institutions act substituted municipal councils for town trusts. Under this act only a few areas were incorporated; it was repealed, except in so far as it affected Perth, by the more comprehensive municipal institutions act of 1895, which was itself repealed by the municipal corporations act of 1906. This act with amendments is now in force. Under its provisions the governor is authorized, upon petition of 50 prospective ratepayers, to incorporate any portion of Western Australia containing rateable property yielding £750 on an annual rate, and to reconstitute municipalities on petition of the council or the ratepayers. The councils consist of a mayor and from six to twelve councillors according to the population of the municipality. Every male adult ratepayer who is a British subject is, with certain exceptions, eligible for election as mayor or councillor; every adult ratepayer who is a British subject, and has paid all rates due for the current financial year, may exercise the local franchise. The term of office is three years; elections take place annually. Plural voting is provided for. All land with certain exceptions is rateable property, rates being assessed on the annual value. Generally the annual value of improved or occupied land is deemed to be the average rent obtainable, less 20 per cent for outgoings; but in no case may the annual value be computed at less than four per cent of the fee-simple value. The annual value of unimproved or unoccupied land is taken to be not less than 7½ per cent of the capital value. General rates may not exceed 1s. 6d. in the £ on the annual value. A special rate may be levied under specified circumstances. The councils have certain borrowing powers, and have a claim to participate in the annual parliamentary grant, provided they have levied a minimum general rate of 1s. in the £ and collected therefrom not less than £300. Newly constituted municipalities, during the first year of their existence, are allowed a subsidy of £2 for every £1 of the produce of the general rate. The city of Perth is subject to the acts governing other municipalities. In 1923 there were 21 municipalities in Western Australia, covering an area of 58,981 acres and with a population of 172,881 and property of a capital value of £31,054,031 and of an annual value of £1,810,173.

Under the road districts act of 1919, which consolidated and amended all previous road acts, the governor is empowered to establish a road district controlled by a road board in any part of the State not included in a municipality. In addition to their special functions relating to

roads and bridges (q.v.) these boards (which consist of from 5 to 13 members elected by adult ratepayers who are British subjects) are invested with most of the powers exercised by the municipal councils. Their revenue is derived from rents, fees, fines, and moneys payable in respect of general, local or loan rates. Rates are levied on the unimproved capital value or, in town-sites, on the annual value. In 1923 there were in the State 121 road districts covering an area of 975,828 square miles.

Until 1886 provisions relating to health and sanitary arrangements were included in the municipal acts; in that year was passed a health act which authorized the appointment of a central board of health, and of local boards in the municipalities, the expenses of the central board being met by the government and of the local boards by a health rate levied by the municipal councils. In 1892 the members of any municipal council were constituted the local board of health; in 1895 the governor was empowered to appoint a local board of health in any area defined by order-in-council, the expenses of which were to be met by the central government; in 1898 all local boards were authorized to levy a special health rate. The consolidating health act of 1911 (which is still in force) substituted a commissioner of public health for the central board, and provided that, where a health district was conterminous with a road district, the road board should be the local board of health. Boards of health may therefore be constituted by municipal councils or road boards, or may be established independently. In 1923 there were 125 local boards of health in the State. Local authorities contribute to the expenses of the fire-brigade service, and are represented on the central board.

Tasmania.—Until 1906 Tasmania was divided into districts of various kinds, each controlled for a specific purpose by a board. These districts had to do with (*a*) main roads, (*b*) roads, (*c*) rabbits, (*d*) fruit, (*e*) public recreation, (*f*) health, (*g*) schools, (*h*) works. There were also rural municipalities and town boards, in addition to the cities of Hobart and Launceston. Under the rural municipalities act of 1858 any town (or any electoral, police, or road district) could be proclaimed by the governor on petition of at least 50 persons concerned who were proprietors or occupiers of property of the annual value of not less than £20. The control of such municipalities as were proclaimed was vested in a council of six members, elected by adult males owning or occupying property of the annual value of £15—provided that, if they were aliens, they held letters of denization. The functions of the council covered the care and management of public roads and streets, the control of the police, water-supply, licensing butchers, registration of dogs and the administration of common-lodging-house and impounding acts. Councils were empowered to levy rates, and received a government subsidy. This act was amended from time to time, but no new principle was introduced. A town boards act passed in 1884 empowered the governor to proclaim towns, but did not apply to any town situated within the boundaries of a rural municipality. Provision was made for the election of town boards, which administered the police act of 1865 with respect to the health and improvement of towns. They were authorized to levy rates. Amending acts vested in them additional powers. All separate districts, together with rural municipalities and town boards, were abolished by the local government act of 1906, under the provisions of which a commission was appointed to divide the State into not more than 60 districts, and to subdivide each district into not less than three nor more than five wards. The cities of Hobart and Launceston were exempted from the provisions of the act. Forty-nine districts were established at the time, but the number has not remained constant. Under the act and its amendments the governor is empowered to incorporate municipalities, to alter boundaries, etc. In each municipality the number of councillors is three for each ward; the warden is elected by the councillors from among their number. Every male elector of a municipality who is resident or has a place of business therein is, generally speaking, eligible for election as councillor; the local franchise may be exercised by any adult ratepayer who is a natural-born or naturalized subject, and by any corporation or joint-stock company the name of which appears on the assessment roll. Plural voting is provided for. A council may define a local district, and assign to it a special standing committee with power to exercise functions vested in it by the council. Every council is empowered to exercise within the limits of its jurisdiction all the powers conferred upon (*a*) the council of a rural municipality by the rural municipalities act of 1865, the rabbit destruction amendment act of 1893 and the police act of 1905; (*b*) the trustees of a road district and a main road district board by the roads act of 1884; (*c*) a board of a town by the town boards act of 1896; (*d*) a local authority by the public health act of 1903; (*e*) a fruit board by the codlin moth act of 1888; (*f*) the trustees of a public recreation ground by the public recreation grounds act of 1888; (*g*) the trustees of a public cemetery by the cemeteries act of 1865; (*h*) a council of a rural municipality as the trustee of a water district; (*i*) a board of advice by the education act of 1885; (*j*) the chief of any inspector of sheep under the Californian thistle act of 1883, with extension of such powers to other noxious weeds. Councils may unite by permission of the governor for the construction of certain works, etc. General and special rates are levied on the annual value of all properties with certain exemptions. Councils have, in addition, borrowing powers, and are entitled to government subsidies. The local government act is administered by the minister for lands and works, who is empowered to settle disputes; local by-laws must be approved by the attorney-general; municipal accounts are subject to government audit. The governor-in-council is empowered to regulate elections, to repeal by-laws, to receive and dispose of petitions, etc.

The cities of Hobart and Launceston are not subject to the general provisions of the local government act. By the Hobart Town commissioners act of 1846 Hobart was divided into five wards, each represented by three commissioners elected for two years; municipal councils for both Hobart and Launceston were constituted in 1852. The city of Hobart was incorporated in 1857, and Launceston in the following year. In 1893 all acts relating to the corporation of Hobart were repealed by the Hobart corporation act of that year; those relating to Launceston were repealed by the Launceston corporation act of 1894. The provisions of these acts, with amendments, are still in force.

In 1922 there were 49 municipalities in Tasmania. The municipalities are represented on the local fire brigade boards and contribute towards the expenses, being authorized to levy a special rate for the purpose either on annual or capital value if the municipal fund is insufficient to meet the charge.

In the *Northern Territory* Darwin has been incorporated as a municipality, and a Bagot road district has been created.

Loch, BARON. Henry Brougham Loch (1827-1900), first baron Loch, born on 23 May 1827 and entered in the navy at the age of 13, left it in 1842 and in 1844 was commissioned cornet in the Bengal cavalry. In 1852 he was made adjutant and second-in-command of Skinner's Horse; in 1854 he was sent to Bulgaria and the Crimea (with the local rank of major) to organize irregular Turkish cavalry; from 1857 to 1860 he was attached to Lord Elgin's missions to China and Japan, in 1858 taking to England the treaty of Yeddo, and in 1860 that of Tientsin, after having been treacherously captured by the Chinese and exhibited in a cage along with the correspondent of *The Times*. After a couple of years spent as private secretary to the then home secretary, he was in 1863 made lieutenant-governor of the Isle of Man; in 1882 became commissioner of woods and forests; and in 1884, the Marquess of Lorne being unable to accept the position, was made governor of Victoria, reaching Melbourne on 15 July of that year. His term of office practically coincided with the prosperous years of the Gillies (q.v.) regime, and his lavish hospitality and encouragement of philanthropic and educational movements soon made him exceptionally popular. In March 1889 he took leave of absence to visit England, and during his stay there was persuaded by the British government to undertake the administration of South African affairs as high commissioner for South Africa and governor of the Cape Colony. He therefore returned to Melbourne for a month only (18 October to 16 November 1889), and proceeded thence to Cape Town, where he remained till 1895. Retiring in that year with a barony, he lived privately in England till his death on 20 June 1900. (C.B., 1861; K.C.B., 1880; G.C.M.G., 1887; G.C.B., 1892; P.C. and baron, 1895.).

Lockyer, EDMUND (1784-1860), born at Plymouth on 21 January 1784, in 1803 entered the army (ensign, 1803; lieutenant, 1804; captain, 1805; major, 1819). With the 19th regiment he served in India and Ceylon, but in 1824 exchanged into the 57th regiment, while quartered in Ireland, and in 1825 sailed from Portsmouth in the *Royal Charlotte* with a detachment of that regiment, reaching Port Jackson on 28 April. Under instructions from Sir Thomas Brisbane, he left Sydney on 1 September in the cutter *Mermaid* to explore the Brisbane River; although it was in flood, he navigated it for a distance of 121 miles, and returned to Sydney on 16 October. He reported very favourably on the area he had traversed, and mentioned the discovery of a coal-seam, specimens from which he brought back for examination. In 1826 the British government, fearing the formation of a French settlement on the western coast of Australia, directed that an expedition should be despatched from Sydney without delay to occupy some station on that coast. Under instructions from Darling, Lockyer in November 1826 sailed in the brig *Amity*, with a detachment of the 39th regiment and a party of convicts, to establish at King George's Sound a settlement of which he was appointed commandant. Darling's instructions to him were detailed and important; if he found the French already in possession, he was to tell them that 'the whole of New Holland is subject to His Britannic Majesty's Government' but, if he reached the Sound first, and French explorers came later, he was merely 'to avoid any expression of doubt of the whole of New Holland being considered within this Government, any division of it, which may be supposed to exist under the designation of New South Wales, being merely ideal.' Lockyer left Sydney on 9 November, put in at Port Dalrymple on the 20th, reached Hobart east-about on 1 December, and anchored in Princess Royal Harbour—the inner basin of King George's Sound—on the 25th. He succeeded in establishing friendly relations with the aborigines (after a brief trouble resulting from their previous brutal treatment by visiting sealers), founded a village on the site afterwards known as Albany, and formally annexed the territory on 21 January 1827. Having fulfilled his mission, he returned to Sydney on 3 April in H.M.S. *Success* with Captain James Stirling (q.v.). In 1827 he explored the Grose valley in the Blue Mountains, but failed to penetrate it. In September 1827, deciding to settle permanently in Australia, he sold his commission and retired from the army, and in November was appointed police magistrate at Parramatta. On 6 June 1828 Darling made him principal surveyor of roads and bridges, but, the colonial office having decided to abolish this office, on 1 January 1830 he handed over his department to the surveyor-general, T. L. Mitchell. In 1827 he had settled at Ermington near Parramatta, and in 1828 acquired by grant and purchase (the grant being a reward for his work in Western Australia) a property near Goulburn which he called Lockyersleigh. In 1847 he took a prominent part at Goulburn in the anti-transportation movement. In January 1851 he attempted to develop an iron deposit near Goulburn which also gave indications of copper, but had no success; over 30 years later the wall of the shaft he sunk was found to contain gold, but not in payable quantities. In 1852 he was appointed sergeant-at-arms to the legislative council, and in 1856 usher of the black rod to the new council. He died on 10 June 1860.—A son, NICHOLAS COLSTON LOCKYER, born at Sydney on 6 October 1855, became Commonwealth comptroller-general of customs in 1910, was a member of the inter-State commission in 1913-20, served as honorary comptroller of A.I.F. canteens during the war, with the honorary rank of major on the retired list, and in 1917 acted as first comptroller of repatriation for seven months, retiring when he had organized the department. In 1921 he was made chairman of the A.I.F. canteens funds trust, which administers the McCaughey bequest for the education of soldiers' children. (I.S.O., 1906; C.B.E., 1916.)

Locusts. See GRASSHOPPERS AND LOCUSTS and CICADAS.

Loftus, LORD. Augustus William Frederick Spencer (1817-1904), fourth son of the second marquess of Ely, was born at Clifton near Bristol on 4 October 1817, privately educated, and trained by his father for the

diplomatic service; his first appointment—to the British legation at Berlin—was dated on the first day of Queen Victoria's reign. His career in diplomacy, which was exceptionally brilliant and important, concerns Imperial rather than Australian history; he was a member of a special mission to various German courts during the revolution of 1848, and served in Prussia during the Crimean war, at Vienna during the Franco-Austrian war, again at Berlin during the Schleswig-Holstein crisis, and—as ambassador—during the Austro-Prussian and Franco-German wars, while from 1871 to 1879 he was ambassador at St. Petersburg. Desiring easier work in a warmer climate, he was at his own request in 1879 made governor of New South Wales, holding the post from 4 August 1879 to 9 November 1885. His term of office included several events of importance to Australia—the completion of direct railway communication between Sydney and Melbourne in 1883, the conferences preliminary to federation of 1881 and 1883, the Sydney International Exhibition of 1879, the visit of Princes Albert and George in 1881, and the despatch of troops to the Sudan in 1885 (see SUDAN CONTINGENT); but only in connection with the last-mentioned event is it asserted that he exercised any personal influence, and the claim that he first suggested the sending of these troops is disputed by adherents of W. B. Dalley and Sir E. Strickland. Returning to England in 1885, he busied himself with the compilation of diplomatic memoirs extending to 1879, and died at Ascot on 7 March 1904. (G.C.B., 1866.)

Logan, PATRICK, entering the army early in life, served in the Peninsular war and was present at six general engagements. On 3 April 1823 he was commissioned captain in the 57th regiment, and in the following year proceeded with it to New South Wales, reaching Sydney in 1825. On 6 March 1826 he was detached with his company to take charge of the new settlement at Moreton Bay, where (although he was not actually the first commandant) he erected most of the necessary buildings—and did the work so thoroughly that until comparatively recent times many of them were in occupation, the old treasury being his military barracks, the observatory his windmill, and the lower floor of the State stores in William-street his commissariat store. As commandant (from the end of 1826 onwards) of a penal station specially formed for the reception of criminals convicted and sentenced in New South Wales—which must, therefore, be a place of real punishment for the worst offenders—his rule was necessarily strict. While actively ruling his small domain, he found time for many journeys of exploration, discovering in October 1826 the river which Darling named after him, and in 1827 investigating by himself (and in 1828 with Allan Cunningham) the south-western ranges of the Brisbane watershed and on 3 August 1828 climbing Mount Lindesay—as it should properly be spelt—for the first time. (This hill is now known as Mount Barney.) In 1830 his regiment was due for relief, and Logan prepared to hand over the post, but desired first to complete a detailed and accurate map of the district. On 9 October he set out to survey an area on the upper Brisbane; on the 11th, when near the Pine ranges, his party met unfriendly blacks, but drove them off; on the 17th, his survey being practically finished, Logan rode away by himself towards Mount Irwin (now known as Mount Beppo) to follow the tracks of a lost horse, and did not return. Four days later the body was found in a shallow grave, the head beaten in with waddies. The reason for the murder was never discovered; but the rumour, set about in the first place by unruly convicts, that other convicts had persuaded the blacks to avenge their wrongs, may be entirely disregarded, and would not be mentioned here had it not been repeated in books published many years later. His body was taken to Sydney, where it received a public funeral.

Log-runner, a genus (*Orthonyx*) of terrestrial birds, frequenting the scrubs of eastern Australia and New Guinea. These birds, of which there are three species, are among the most anomalous of the Australian region, and their relationship to other perching birds is quite uncertain. They were originally placed among the creepers (Certhiidae), and two New Zealand birds known as 'canaries' were also included in the genus. More recently they have been placed in the so-called family Timaliidae, an artificial collection of birds which did not belong to any other recognized family. It seems best to create for them a special family, Orthonycidae, as has recently been done by G. M. Mathews.

The Spine-tailed Log-runner (*O. temmincki*) is an inhabitant of the scrubs of southern Queensland and New South Wales. It is mottled with brown and black above, with yellowish-

Spine-tailed Log-runner.

white on the breast; the male has the throat white, in the female it is pale chestnut. The tail is rather long, and the shaft of each tail-feather is continued as a spine beyond the barbs. The legs and toes are very long and stout for the size of the bird—which is not much larger than the 'willy wagtail;' it uses them for scratching away leaves and sticks beneath which it finds its food. The name 'log-runner' is not specially appropriate, as the birds keep entirely to the ground, and move by hopping rather than running. The curious form of the tail seems to have no relation to the birds' habits. In other birds with similarly modified tail-feathers the tail is used to support them when climbing trees (woodpeckers) or clinging to cliffs (spine-tailed swifts).

The Black-headed Log-runner (*O. spaldingi*) is a decidedly larger bird, about the size of a thrush, with dark brownish-black plumage above and white below; as in the other species, the throat is white in the male, chestnut in the female. As far as is known, this species is confined to the scrubs near Cairns in northern Queensland. In habits it resembles its smaller relative, but is said to be a noisier bird.

The New Guinea Log-runner (*O. novaeguineae*) is closely similar to the southern Australian form, not as might have been expected, to the northern one.

Log-runners construct large domed nests of moss, with a lateral entrance near the bottom,

placed usually on the ground or on the top of a low stump. The eggs are pure white, and very large for the size of the birds; the spine-tailed log-runner lays two, the black-headed species only one.

W. B. A.

Lomatia, a genus of the family Proteaceae, consisting of shrubs or trees with white or pale yellow flowers arranged in pairs. It is represented in extra-tropical South America, but the species indigenous to Australia are endemic. The corolla has an oblique tube open along the lower side and tapering at the top, the segmented lobes cohering for some time; fruit a leathery follicle opening on one side, the valves spreading until the open pod is almost flat; seeds imbricately folded in the fruit, and produced into a broad terminal wing; leaves alternate, entire, toothed, or deeply divided. *L. longifolia* (Mountain Beech), has a hard, light-coloured ornamental wood, used for turnery; *L. ilicifolia* (Native Holly) is an ornamental shrub with holly-like leaves; *L. silaifolia* has finely dissected leaves simulating a fern-frond.

Longbottom, WILLIAM (1799-1849), born at Bingley in Yorkshire on 10 December 1799 and educated locally, was in 1827 admitted to the Methodist ministry and sent by the London Missionary Society to India, where he worked arduously for nine years. In 1836 it was decided to transfer him to Cape Town for the sake of his health, but after a short stay there he went back to India. In 1837 he was ordered to Western Australia, having to travel thither via the Mauritius and Tasmania; and, leaving Hobart in the *Fanny* on 9 June 1838, was wrecked on the 21st on the Coorong beach in South Australia (east of the Murray mouth), rescued after severe trials by the *Lady Wellington,* and brought to Adelaide on 17 August. The small Methodist community there (which lacked a minister) received him with enthusiasm, and he determined to stay among them; but his health soon gave way again, and he was appointed to New Norfolk in Tasmania. Here he stayed till 1843, when he was removed to Sydney; but, hearing that the Church's affairs in South Australia were in confusion, he volunteered to return, reached Adelaide in April 1844, and in spite of bad health worked there for two years more. In 1846 his health failed altogether, and he was forced to resign, members of other Churches as well as of his own contributing a comfortable pension. He died in Adelaide on 29 July 1849.

Long-snouted Honey-mouse, a small mouse-like marsupial (*Tarsipes spenserae*) belonging to the opossum family (q.v.) but with some special features of its own. The head and body are only three inches long, the tail four inches. The short coarse fur is grey above, striped with black or brown, yellowish-white below. The head is long and narrow, with an elongated muzzle. All the claws are rudimentary, except those on the second and third toes of the hind-foot, which are very closely united (syndactylous). The elongated, thinly-haired tail is prehensile. The long-snouted honey-mouse is confined to south-western Australia, where it appears to be fairly numerous in certain districts; it is nocturnal and arboreal, and its chief food consists of honey (which it extracts from flowers by means of a long, narrow tongue) and soft-bodied insects.

W.A.H.

Longstaff, JOHN, born at Clunes in Victoria in 1862, in 1883 joined the art school conducted by G. F. Folingsby in connection with the Victorian National Gallery, and in 1887 won the first travelling scholarship awarded by the trustees of the gallery with a notable picture, 'Breaking the News.' By sheer coincidence the exhibition of this picture followed closely on a mining disaster at Creswick, and many people believed—indeed, it is still believed widely—that it was a deliberate portrayal of an actual incident. The scholarship took Longstaff to Paris, where he studied under Fernand Cormon and gained a *mention honorable* at the Old Salon in 1891 for his 'Young Mother.' In 1893 he made successes at the Royal Academy with 'The Sirens' (now in the Melbourne gallery) and at the Old Salon with 'A Portrait Study'—usually known as 'The Woman in Black'—now in the Sydney gallery. Since that time he has devoted himself mainly to portraiture, being represented at Sydney by portraits of (among others) Henry Lawson (1900), King Edward and Queen Alexandra (1904), and General Monash (1918); in the Melbourne gallery, curiously enough, he is chiefly represented by historical work—'Bush Fires in Gippsland' (1898) and 'The Death of Burke and Wills' (1901), both specially commissioned.

W. M.

Long Toms (also known as needle-fish), members of the family Belonidae, in England and America called garfish—in Australia that name has been wrongly but irrevocably applied to the half-beaks of the family Hemirhamphidae. The Belonidae have the upper and lower jaws equally produced, and armed with rows of needle-like teeth. More than a dozen species occur on the temperate and tropical coasts of Australia, and all are excellent food-fishes. They have green-coloured bones—a peculiarity which has led to the erroneous belief that they are unwholesome as food. Long Toms have the habit of leaping from the water, either when pursuing their prey or in escaping from their enemies. They are voracious fishes, and occasionally attain a length of six feet.

A.R.McC.

Lonsdale, WILLIAM (1800-1864) was commissioned 1st lieutenant in the 4th (King's Own) regiment on 4 March 1824 (captain, 1834), and reached New South Wales on 14 December 1831 with a detachment of his regiment in the *Bussorah Merchant.* After serving in Tasmania (1831), at Cox's River (1832), and at Port Macquarie (1834) he was stationed at Parramatta until September 1836. On the 9th of that month he was appointed police magistrate of the new settlement at Port Phillip and commandant of the troops stationed there, with general superintendence of all such matters as required the immediate exercise of the authority of the government. He reached Port Phillip in the *Rattlesnake* on 29 September, a staff of surveyors with apparatus and provisions following soon afterwards. Lonsdale's salary at the time was £250 per annum, increased to £300 when in March 1837 he resigned from the army. At first he was handicapped by lack of accommodation, and was obliged to reside on board the *Rattlesnake* until 30 November, while a four-roomed cottage was erected. His first business was to determine the official site of the new settlement—then popularly known as Bearbrass. He decided to abide by the existing site, since

at the rival site (Point Gellibrand, now Williamstown) the water-supply was very deficient.

Following the precedents of Sydney and Hobart, he proposed to name the town Glenelg, after the secretary of state for the colonies; but Bourke (who confirmed the choice of site, but did not like it) gave the King's name to the site he personally preferred—Williamstown—and that of the prime minister to Melbourne. The first census of the district was taken in November 1836, when 364 residents were enumerated. Immigrants continued to arrive, and Lonsdale was soon confronted by the difficulty of placing newcomers in suitable employment. The erection of requisite public works and the survey of the district were proceeded with, but the work of survey was hampered by unfriendly relations between Lonsdale and the surveyors—Hoddle, indeed, refused to acknowledge Lonsdale's authority outside his sphere as police magistrate. To deal with the aborigines Lonsdale took into government employ William Buckley (q.v.), but he proved unsatisfactory as an official and retired after a year's service. After an unsuccessful attempt to establish a Church of England mission house under the care of George Langhorne, a department for the protection of aborigines was established under instructions from the colonial office, and in 1839 George Robinson (q.v.) was invited to become first protector. Meanwhile Bourke had advised the colonial office that more adequate provision should be made for the administration of the distant settlements at Melbourne and Geelong, and suggested that a lieutenant-governor or superintendent be appointed, with civil and military authority over all the southern districts of New South Wales, subject to the authority of the governor in Sydney. Charles Joseph Latrobe (q.v.) was therefore made superintendent of the Port Phillip district, and reached Melbourne on 30 September 1839. Lonsdale retained his position as police magistrate for eight months, and was then appointed sub-treasurer of the new administration. He was subsequently appointed interim mayor of Melbourne in 1842, acting-superintendent in 1846-7 (during Latrobe's absence in Tasmania), and colonial secretary of the new colony after separation. This position he resigned in 1853, and returned to England, where he died on 28 March 1864.

Loquat. See FRUIT-GROWING.

Loranthaceae, a family of much-branched shrubs, parasitical on the branches of trees and shrubs—except *Nuytsia* (q.v.) and *Atkinsonia* (q.v.)—abundant within or near the tropics, but less common in temperate regions. Of the five genera indigenous to Australia three (*Nuytsia, Atkinsonia, Notothixos*) are endemic. The petals or perianth segments are 4-6, free or united; fruit a berry or drupe with a single seed. The parasitic species sometimes simulate the shape and colour of the foliage of their host. See ATKINSONIA, LORANTHUS, NOTOTHIXOS, NUYTSIA, VISCUM.

Loranthus, a large genus of the family Loranthaceae, consisting of parasitic shrubs, chiefly tropical and subtropical. They are usually known as 'mistletoes,' their habit of growth resembling that of their near relative the English mistletoe (*Viscum*). Australia has 26 species, the majority endemic. The flowers are elongate, from bright red to dull green; petals 4-8, free, or more or less united into a tubular corolla; fruit a berry; leaves usually opposite. Some loranths are parasitic upon their own kind, as well as upon other trees. Birds eat the succulent berries, and distribute the seeds in their droppings.

Lord, EDWARD (1780-1859), joined the royal marines as second lieutenant on 12 September 1798 (1st lieutenant, 1804), and reached Australia with the detachment that accompanied Collins to Port Phillip in 1803. When, early in 1804, Collins moved to the Derwent, the senior marine officer was left behind, and Lord found himself in charge of the guard at Hobart. There he built the first house, near the corner of Harrington and Macquarie streets, a site so far from the camp that it was known as 'the house in the bush.' In 1805 he applied for leave to return to England; but Collins sent him to Sydney for King's approval, and King, finding him interested in live stock, after six months sent him back to Tasmania with a number of ewes and 'a ram as near the Spanish breed as Government is in possession of.' In 1806 his flock of 100 sheep was the largest privately owned in Tasmania, but by 1809 two other breeders had passed him. In 1807 he became senior officer next to Collins himself, and when Collins died suddenly on 24 March 1810 took over charge of the colony; but Macquarie, preferring to have in Tasmania a deputy he knew he could depend on, hastily sent over John Murray, a captain of his own regiment, told Lord he could go back to England as soon as he liked, and rather peremptorily relieved him of all his offices. Early in 1811, therefore, Lord left Tasmania on 12 months' leave, and at the expiration of it retired from the marines and returned to Hobart as a private settler and merchant. In this capacity he repeatedly fell foul of the authorities: Macquarie listed him for Sorell's benefit as a dangerous and troublesome person, and described him to Bathurst as vindictive and implacable. Brisbane talked about his 'sordid interests,' and proposed to remove him from the magistracy. On the other hand Sorell considered his conduct 'unexceptionable' and in 1818 made him a member of the lieutenant-governor's court, and Bathurst, meeting him while on a visit to England in 1820, specially commended him to Sorell's attention—a recommendation which procured his appointment in 1821 to the magistracy. He was then the largest proprietor in the settlement, and in 1823 was one of the original proprietors of the Bank of Van Diemen's Land. By that time, however, he was residing in England, where he lived for the rest of his life, dying in London on 15 September 1859.

Lord, SIMEON (1771-1840), was in 1791 transported to New South Wales (his offence is not known for certain, but Davey in 1817 declared it was picking pockets and Bigge called it 'insignificant'), and reached Port Jackson in the *Atlantic* on 20 August. He was at first assigned as servant to an officer of the New South Wales Corps, but developed a business ability that soon made him his own master. By 1798 he was acting as agent for certain ship-captains, and in 1800 was one of a syndicate that persuaded Hunter to let them purchase goods direct from incoming vessels, and so broke up the Corps' monopoly of trading; the same year he and Hugh Meehan bought a prize ship, and in 1801 began trading on their own account. By 1803 he was a licensed auctioneer, and in 1804 was registered as a shipowner dealing in wool, oil, and sheepskins. By 1806 he must have been rich, for at least one debtor owed him

£2300 and was given easy terms; but in the same year he fell foul of Governor King, who suspected him of illicit trade with the French, then our enemies. In 1807 he quarrelled with Governor Bligh over the method of trans-shipping some cargo, was sentenced without trial to a month's imprisonment, and became Bligh's bitter enemy (Bligh was censured by the colonial office for this injustice); he was one of the six who signed the pre-mutiny requisition to Johnston (the requisition still extant was possibly drawn up, and certainly signed by most of the petitioners, after Bligh's arrest), and for a time was high in favour with the mutineers. But Lord, like the Blaxlands (with whom he at this time went into partnership), was primarily a business man, and only interested in politics so far as it affected his trade. Johnston was at loggerheads with him by April 1808, and Macarthur (for once agreeing with Bligh) accused him of acquiring a fortune by infamous means. Foveaux, however, took him back into favour, made him government auctioneer, and gave him the freehold of the block in Macquarie Place, Sydney, on which he had built the well-known house that maintained his memory until early in the present century. Macquarie favoured him greatly, made him a magistrate on 17 May 1810, and encouraged him to frequent government house as a guest.

Lord had by now launched out into useful speculations of several kinds. He became prominent in the whaling and sealing industry, and promoted attempts to import and manufacture New Zealand flax; the unfortunate *Boyd*, whose crew was massacred by the Maoris in 1809, was chartered to him, and in 1815 he was again asking Macquarie for leave to form the 'New South Wales New Zealand Company.' In 1808 he was interested in pearl fisheries; in 1812 he applied for permission to mine iron ore at Port Dalrymple in Tasmania; in 1813 he was trading in sandalwood; in 1819 he backed Thomas Kent (q.v.) in experiments for extracting tannin from wattles and soda from Tasmanian seaweeds. In 1815 we find three Bengali workmen in his employ, but their special duties are not indicated. But during the intervening years the feeling of the free settlers against Macquarie's intimacy with emancipists had grown bitter. Marsden refused to sit on the bench with Lord, but other free magistrates would not go so far. Ellis Bent was sarcastic about his business integrity, and Barron Field (with whom he was associated in 1817 as a member of the supreme court) thought him not 'sufficiently literate,' too much biassed in favour of emancipists, and likely to 'take every advantage as a Tradesman.' The latter charge was probably a result of local prejudice, for Bigge notes that his trustworthiness as an agent commended him to 'those who were strangers to the colony.' In 1819, however, his lack of experience and breeding produced awkward scenes in court of which Bigge and others took advantage to put pressure on Macquarie, and at the governor's instigation Lord in 1821 resigned his justiceship and devoted himself for the rest of his life to business. It is said that he was the first man to manufacture home-grown wool in his mills at Botany; these, as well as his hat factory, were in existence before 1819. One instance of his excellent business instinct may be noted. Foveaux had, as mentioned above, given him the freehold of land in and near Macquarie Place, and Macquarie had resumed about half an acre of it to create the park that still exists there, but had not definitely allotted him compensation; Lord after many years' persistence persuaded Governor Darling to settle the matter, and in 1828 obtained nearly 18,000 acres of land on the Hunter and beyond the Blue Mountains in exchange for the half-acre. In later life he went to live near his Botany mills, and there he died on 29 January 1840. His family must not be confused with that of Edward Lord, lieutenant of marines, who in 1810 administered for a few months the government of Tasmania.

Simeon's son GEORGE WILLIAM LORD sat in the first and second New South Wales legislative assemblies as member for Wellington and Bligh (1856-9), and from 1859 to 1877 represented the Bogan; he was treasurer in the Martin ministry of 1870-2. From 29 October 1877 to his death on 10 May 1880 he was a member of the legislative council. Another son, FRANCIS, represented Bathurst in the legislative council from 1843 to 1848, and sat in the nominee council from 1856 to 1861 and from 1864 till his death in 1892.

Lord Howe Island is situated in 31° 33′ S. lat., 159° 5′ E. long., 300 miles due E. of Port Macquarie and 450 miles NE. of Sydney. The nearest land eastward is Norfolk Island (500 miles) and south-eastward New Zealand (750 miles). Nearly seven miles long by an average width of one, the main island has an area of 3220 acres, of which from a quarter to one-third have been estimated as capable of cultivation. Detached islets are Gower Island at its southern end, the Sugar-loaf to the north, Mutton-bird Island about half a mile to the east, and Goat or Rabbit Island within the western lagoon. A quarter of a mile northward lie six rocks known as the Admiralty Islets; North Island and its companion rock lie beyond these. Ten miles SE. rises the almost inaccessible Ball's Pyramid (named after the discoverer of Lord Howe Island), which rears its 1816 feet sheer from the ocean with a base only 60 by 25 chains. The largest of the Admiralty Islets is nearly half a mile long, probably 300 feet high, and, like the main island, precipitous on its eastern face. A landing here, as on Mutton-bird Island, can only be effected in the calmest weather.

History.—The island was discovered by Lieutenant Henry Lidgbird Ball, commander of H.M. tender *Supply*, on 17 February 1788, during a passage from Port Jackson to Norfolk Island. Ball examined the island on his way back to Port Jackson, and reported that it abounded in turtle. On 6 May, therefore, Phillip sent him back for a supply, as fresh meat was scarce in the settlement; but he had to report that no turtle could be found, nor any sign of their breeding there, and that the water-supply was poor. In January 1790 he tried again, and after much hunting secured three turtles, but found that there was no good anchorage. Consequently the island was for many years neglected. Whalers occasionally put in, and some introduced pigs, goats and, unfortunately, cats, which almost destroyed several rare birds—among them a woodhen (*Ocydromus sylvestris*), a sort of guinea-fowl and a ground-pigeon. *Notornis alba*, another gallinule, was extirpated by the crews of whalers, who found it as edible as it was friendly.

In 1834 three white men from New Zealand—Ashdown, Bishop, and Chapman—accompanied by three Maori girls and two Maori boys, landed

from the whaling bark *Caroline* and formed the first settlement. They were bought out by a Sydney ironmonger named Dawson and his partner Poole for £350; Dr. Foulis came in as a third partner. The original settlers then returned to New Zealand, and in 1843 Wright, McAuliffe, and Hesketh, with their wives, went to the island in Dawson's little vessel the *Rover's Bride*, followed by Margaret Andrews and her husband and A. P. Mosely; but Dawson found his venture unprofitable, and abandoned it, only those remaining on the island who chose to do so independently. The patriarchal method of Poole's government is shown by his treatment in 1843 of a new arrival, who would not work, by chaining him to a tree, confining him in stocks, and finally taking him to Sydney in a cask. In 1851 Dr. Foulis furnished the government with a report stating that about 16 persons were resident, and that from 60 to 80 whalers put in for wood, water and provisions; the residents kept poultry, pigs and goats, and cultivated maize, potatoes and onions—the last being especially prolific and good for export. In 1869 there were 35 residents on the island, and in 1875 it was proclaimed a reserve. The census of 1921 showed the population as 121. The chief industry is the gathering and export of *Howea* (better known as *Kentia*) palm seed. Lord Howe Island lies east of the 154th degree of longitude, which is the eastern limit of jurisdiction of the government of New South Wales; consequently in the constitution acts and in proclamations applying to the whole State, it has to be specifically included by name.

In July 1912 a royal commission appointed to enquire into the palm-seed trade issued a report that resulted in the formation of a board of control, sitting in Sydney, for island affairs, with a local advisory council on the island itself. Under the board the residents are mostly shareholders in a company controlled by the government. A resident born on the island acquires so many shares upon attaining his majority. No land is privately owned, and the residents pay no rent. The island is included in the King division of the Sydney electorate.

Neither implements, nor rock carvings, nor any other traces of an aboriginal population have been discovered.

A survey of the island was made in 1835 by H. F. White, whose map was apparently first published by Hill in 1878. Many of the original names of prominent features—presumably given by White—have since been altered. A good map was issued with the *Report on Lord Howe Island* made by J. Bowie Wilson in 1882. The island is crescent-shaped, and consists of three volcanic ridges, connected by lower undulating land formed by wind-blown coral sand. Of these ridges by far the greatest—forming, roughly, half the total land area—is the southern massif, with its two giants Mount Gower (2840 feet) and Mount Lidgbird (2504 feet) and the lesser hills North Hummock and Intermediate Hill (647 feet). The first two are separated by the deep Erskine valley. Intermediate Hill sends out an eastern spur towards Mutton-bird Island, with which it was probably connected in recent geological periods. The northern ridge consists of semi-detached peaks, with a bold sea-face of precipitous cliffs 600 to 700 feet high. The chief feature of this is Mount Eliza, an isolated peak—'cut vertically in half, concave towards the sea' says Etheridge; northeast of this lies North Peak, or Poole's Lookout. The third (the intermediate) ridge is formed by a conical hill, Mount Look-out (414 feet), with its seaward extension, known locally as Clear Point, but marked on the admiralty chart as Observatory Point. On the eastern side three sandy beaches occur, known as Ned's Beach, Middle Beach, and Blenkinthorpe Bay; the second contains the best landing-place, immediately north of Clear Point. A short, narrow inlet near Mount Eliza is known as the Gulch. A fringing coral reef forms the chord of the island crescent, extending from Phillip Point to the base of Mount Lidgbird, and within it lies the lagoon—about four miles long by an average breadth of half a mile—having narrow entrances through the reef, and washing a beautiful stretch of sandy beach 1¼ miles long at the middle of the island. Hedley has remarked that Lord Howe is the farthest south of islands having coral reefs. The chief freshwater creeks are Deep Creek, which with its branch Soldier's Creek drains the western flanks of Intermediate Hill and Mount Lidgbird; Freshwater Pool, a rocky gorge of the latter mountain; the Valley of the Shadow of Death near Middle Beach, and a short water-course that drains the eastern part of the northern ridge. Abundant showers, chiefly from the SE., afford an ample water-supply, and nourish the luxuriant vegetation with which the island is clothed.

The tide rises and falls about six feet. Two good anchorages exist; the NE. roadstead, off Ned's Beach in 16-18 fathoms, and the SW. roadstead, outside the middle entrance to the lagoon in 15-18 fathoms. The prevailing winds in summer are from the SE., in winter from the SW.; the latter are often accompanied by violent rain squalls. E. S. Hill states that occasional cyclones from the NNW. devastate narrow areas, while miniature whirlwinds, termed 'wollies' by the inhabitants, sweep from the deep gullies to the sea. The summer temperature seldom rises above 80° Fahrenheit, and the winter climate is genial, so that the island has been termed 'the Madeira of the Pacific.'

Mount Gower may be ascended by two routes. The longer is a rough track round the eastern spurs of Mount Lidgbird; a more hazardous one, known as the Lower Road, skirts the face of the mountains 500 feet above the sea. This is in places but two feet wide; footholds have been cut on it with a pick, but there is little or nothing but the rough surface of the wall as handhold. Mount Lidgbird is even more difficult of access, and requires energetic climbing with the aid of ropes.

Geology.—Two-thirds of the island is composed of volcanic rocks, sections of which may be seen along the coast and on the precipitous sides of the mountains. Thus 'on the face of the North Ridge' says Etheridge 'a section, 700 feet high, shows a successive alternation of beds of agglomerate and a harder and denser rock, seamed in all directions by dykes and veins, a number of which are quite vertical and run up the face of these magnificent cliffs like so many ladders.' 'These volcanic rocks' writes Sir Edgeworth David, 'appear to belong to three leading types, (1) basalt with olivine, (2) basalt without olivine, lateritic, (3) basalt, diabasic: probably of considerable geological antiquity . . . . A vast period of time must have elapsed between the eruption of (3) and (1). . . . All the basalts, with the exception of the diabasic types, are probably not earlier than Tertiary, and some may be post-Tertiary. The

diabasic basalt is probably pre-Tertiary, and may be Palaeozoic.'

A. R. Wallace noted that a submerged bank extends at a depth of about 1000 feet from New Zealand north-westerly to Lord Howe Island; this is confirmed by the soundings made by the *Challenger* expedition. The connection with New Zealand has further corroboration from zoology. According to Etheridge 'there is reason to believe that Lord Howe Island originally formed part of the New Zealand volcanic area, and certainly dates back to the Pleiocene period, perhaps further;' the coral-sand rock is wind-blown (aeolian) in origin, and tallies well with Dana's description of drift-sand rock (*Corals and Coral Islands*, p. 154); and 'the supposition that Lord Howe, as we now know it, was composed of a few small islets is based on the fact that it would require a depression of but comparatively few feet to return it to this condition. This granted, we have but to imagine a slight upheaval, and circumstances favourable for the accumulation of the coral-sand rock would at once exist.'

Natural History.—The crowning glory of Lord Howe Island is its vegetation, which covers the greater part of its surface with a dense growth of plants—many of them peculiar to the island. In the earlier days the undergrowth was partially cleared by pigs and goats liberated by the first settlers; but domesticated goats have been got rid of by mutual consent of the islanders, the pigs have been penned in, and the wild goats and pigs are now confined to the extremities of the island. Travelling is difficult except along the beaten tracks. The islanders largely employ sleighs, wheeled vehicles being scarce. To quote Allan McCulloch:—'The shady paths winding over the island are wonderfully beautiful, and here and there present glimpses of the lagoon and the mountains which are rare pictures of delicate colour and charm. Sometimes they pass through forests of palms which wall them in on each side with a dense growth in every stage, from the fresh young shoots just appearing above the ground to the tall trees whose leaves form a canopy overhead, filtering the sunlight to gleam on the shining green undergrowth.'

There are four species of these palms. The Thatch Palm (*Howea Forsteriana*), the seed of which forms the chief commercial asset of the island, flourishes on the lower ground and up to 400 feet above sea-level; the Curly Palm (*H. Belmoreana*) extends to 1200 feet above; the Umbrella Palm (*Hedyscepe Canterburiana*) is found from the 1000-ft. contour-line to the summit of the two mountains; the Dwarf Mountain Palm (*Clinostigma Mooreanum*) is confined to the summits of Gower and Lidgbird. The thatch palm is confined to coral-sand rock formation; the others are found only on volcanic soil. The most remarkable tree on the island is the Banyan (*Ficus columnaris*) which, starting life as a parasite in crevices of other trees, sends down trailing stems that after a time strangle the host, and later develop adventitious roots that form rope-like stems. These often coalesce to form trunks, a few dozen of which will cover an area of two or three acres.

In the 1882 report of J. Bowie Wilson the prevalence of a disease amongst these trees was noted, due to a psyllid insect, causing defoliation and death on a wide scale. An even wider devastation of the tree is occurring at the present time; photographs by A. R. McCulloch show many dead banyans, probably due to the depredations of insects following the wholesale destruction of birds by the rat pest. A. M. Lea has observed the presence on this tree of the same chalcid wasp (*Pleistodontes froggatti*) that fertilizes the Moreton Bay fig in New South Wales.

'The top of Mount Gower' wrote the late W. W. Watts, 'is a veritable paradise of plant life. Here on this rich plateau may be found fern after fern and moss after moss that occur nowhere else in the world.' Of tree-ferns the most superb are *Cyathea brevipinna, C. Macarthuri,* and the two indigenous species *Alsophila robusta* and *Hemitelia Moorei.* The magnificent *Asplenium melanochlamys* somewhat resembles a young tree-fern. On the slopes of the mountain occur the beautiful ferns *Dryopteris nephrodioides* and *Blechnum Fullagari* (the latter in profusion) as well as three species of *Hymenophyllum*; *H. pumilum* and *H. multifidum* grow in the utmost luxuriance, together with *Trichomanes Bauerianum.* Here also is to be found the rare, large-fronded *Leptopteris Moorei, Polystichum Whiteleggi*—locally known as the 'heavy fern'—and *Polypodium pulchellum,* remarkable for its clothing of reddish-brown hairs. Other parts of the island have ferns of wider distribution, such as *Adiantum aethiopicum, A. hispidulum, Platycerium alcicorne, Marattia fraxinea* (known to the islanders as the horseshoe fern) and *Ophioglossum vulgatum.*

In 1893 Professor R. Tate recorded from the island 207 species of plants belonging to 154 genera; 56 of these species were endemic. His general conclusion is that 'the affinity of the species is certainly greater with Australia than with any other region of the Australasian Province. But, as the flora presents certain marked affinities with that of New Zealand, and keeping in mind the large community of species between Norfolk Island and Lord Howe Island, and the fairly well-marked affinity generically with Norfolk Island and New Zealand, there is no choice but to regard Lord Howe Island as a companion outlier to Norfolk Island of the New Zealand region' (*Macleay Memorial Volume,* p. 214). The affinity, he adds, of the land faunas, particularly in the classes of birds and gastropods, is rather with Polynesia and New Zealand than with Australia.

Zoology.—One of the strongest arguments in support of the relation of the fauna to that of New Zealand is the absence of an indigenous mammalian fauna. The only indigenous lower mammal known is a scarce bat (*Scotophilus morio*). On the other hand certain introduced mammals have rapidly increased. Hill states that about 1845 'a number of cats were sent ashore from a whaleship. These soon became populous and found an easy prey in the native birds. Their descendants, or those of later domestications, still exist in the hills, where are also found goats and swine—the last confined to the southern end.' Mice (*Mus musculus*) were accidentally introduced about 1868, and in two years swarmed over the island. The latest and worst of these pests is the rat, introduced in 1919 from a stranded vessel. 'In two years,' says McCulloch, 'they have made the note of a bird rare, and the sight of one, save the strong-billed magpie and the kingfisher, even rarer. Within two years this paradise of birds has become a wilderness, and the quiet of death reigns where all was melody. The very few birds remaining are unable to breed, being either destroyed upon their nests or driven from

them by the rats, and their eggs eaten . . . . With the birds gone, injurious insects have increased unchecked, and are destroying the produce of the island gardens. The rats also eat the corn ere it ripens, and extract the pulp from bananas, pomegranates and other fruits . . . . Dire distress threatens the residents unless some unsuspected cause brings about a reduction of the rats.' Introduced rabbits existed for a time on Rabbit Island, but were never established on the main island, and appear to have died out.

Birds.—In 1788 the birds (writes McCulloch) 'having no enemies other than of their own kind, for there were neither mammals nor reptiles to prey upon them, knew not what fear meant, and wandered up to observe what strange intruders had come to disturb their seclusion . . . white birds with scarlet bills (*Notornis alba*), about the size of a hen, being plentiful.' These fearless and flightless birds were, alas! good to eat, and the crews of visiting whalers slaughtered them wholesale, while the introduced cats and pigs completed the annihilation. No material record remains of this unique species, save a skin in the Vienna museum and a specimen in the Liverpool museum.

Woodhens (*Ocydromus sylvestris*), that once roamed plentifully over the whole island, are now confined to the upper parts of the mountains. 'A bird whose curiosity overcomes its shyness and comes hurrying out of the forest to investigate the cause of such noises as the tapping of two stones together or the notes of a mouth-organ—approached sufficiently close to be snared with a palm-leaf noose,' says McCulloch. The beautiful little green pigeon (*Chalcophaps chrysochlora*) was in 1907 very plentiful, and so tame that it could easily be snared by a noose at the end of a stick. Hull records 22 species of birds, belonging to 20 genera, as breeding on the island. As with the flora, 'the character of the avifauna is more distinctly Australian than New Zealand; although the woodhen (*Ocydromus*) and the extinct *Notornis alba* and *Nestor productus* may be regarded as of greater value in determining the original route of emigration.' The Mutton-bird of Tasmania (*Puffinus tenuirostris*) breeds in large numbers on the island, and emits at night weird moanings and wailings during the breeding period, while digging burrows in the sandy soil. The Little Mutton-bird (*P. chlororhynchus*) breeds on the smaller islets. The Sooty Tern (*Sterna fuliginosa*), locally known as 'wide-awake,' provides the inhabitants with an abundance of fresh eggs from September to November. Three small lizards occur on the island, of which the commonest (*Phyllodactylus guentheri*) exists also on Norfolk Island and in north-western Australia. In the paucity of its reptiles Lord Howe resembles the Sandwich Islands.

Of the 200 species of fishes recorded by Waite none are peculiar to the island; they are chiefly of Australian affinity. But numerous interesting deep-sea fishes, unknown elsewhere, are thrown up on the beaches from some cause that is not apparent.

Of the 118 shells recorded by Etheridge the most interesting are the land shells, which show several species peculiar to the island. Two of these (*Helix sophiae* and *Bulimus bivaricosus*) are found in immense numbers in damp, shady situations. Among the 24 land shells known in 1889 are two freshwater species of *Bythinella*, found in the steep 'runs' of Mount Lidgbird. The land snails, according to Hedley, are all endemic, and among the inoperculate group the auriculoid *Placostylus* claims affinity with New Zealand, and utterly repudiates kinship with Australian life.

Insects.—A. M. Lea notes the affinity of the insects of the island with those of northern New South Wales, but there is an admixture of New Zealand forms. A large number of 'borer' beetles attack the decaying palms and tree-ferns; the characteristic Australian scarabs and buprestids are almost entirely absent. The most interesting of the endemic insects is a wingless phasma (*Karabidion australe*), locally known as the 'tree-lobster;' these insects live in communities in hollow trees, are night-feeders, and betray their dwellings by the heaps—amounting sometimes to bushels—of their droppings. Wingless crickets are also to be seen by night on the banyans. A cicada (*Psaltoda insularis*) is abundant, and has lately attracted the notice of the wide-awake terns, which frighten the insects from the trees and catch them on the wing. A peculiar freshwater crab (*Halicarcinus*) is found on North Ridge. Land planarians of five or six species are numerous. The rock-pools of the coral-reef are prolific hunting-grounds for the naturalist. Branching madrepores and softer bluish *Xenia* corals form refuges for a vast variety of life: anemones with their curious sub-parasitic fish (*Amphiprion*); a rare swimming crab (*Caphyra*), of the exact tint of its coral host, but with a pattern that delineates the surrounding polyps on its carapace; a species of trepang, sea-urchins, clams, starfish and other wonders.

Lord Howe Island must not be confused with Howe Island in the Recherche Archipelago (Western Australia), or with a small group known as Lord Howe Islands, or Ongtong Java, near the Solomon Islands. There are Lord Howe Islets in the Santa Cruz and Society groups.

E. S. Hill's *Official Visit to Lord Howe Island* (1870) epitomizes previous history well. The natural history of the island is dealt with in many papers in the *Records* of the Australian museum, the *Australian Museum Magazine*, and the *Proceedings* of the Linnean Society of New South Wales.

Lorikeet, Lorilet, Lory or Lowry. See PARROTS.

Lotus, a widely-dispersed, chiefly tropical genus of the family Leguminosae; all the species indigenous to Australia are herbs. The flowers are yellow, pink, or white in small clusters, each cluster supported by a leafy bract; leaves with 4-5 leaflets. A variety of *L. australis* (Native Bird's-foot Trefoil, because its three upper leaflets are arranged as in the English clover) at certain periods of its growth contains prussic acid in sufficient quantities to poison stock; some authorities, however, regard it as a useful fodder-plant.

Lotus-bird. See WADERS.

Lowan. See MOUND-BIRDS.

Lowe, NATHANIEL, commissioned lieutenant in the 40th regiment on 29 November 1821, sailed with his regiment for New South Wales early in 1824, and was detached soon after his arrival for service with the mounted police, at first at Bathurst, then at Wallis Plains (now Maitland). In June 1826 he was sent with a detachment of police to apprehend some aboriginals who were alleged to have committed mur-

ders of white men in the upper Hunter district, and was afterwards charged with having (*a*) allowed his men to shoot three natives while in custody, (*b*) ordered the shooting of a native prisoner, Jackey Jackey, who was supposed to have committed a murder. To the first charge his answer was that the natives were shot while attempting to escape, and this seems to have been accepted; the second was taken up by the anti-Darling press and used as a weapon against the governor, whose endeavours to prosecute a full enquiry into the matter were repeatedly thwarted by accidents and by the unwillingness of civilian witnesses to give evidence. After some trouble Lowe was arraigned before the supreme court on 18 May 1827 for the wilful murder of Jackey Jackey. His counsel, W. C. Wentworth and Dr. Wardell, raised the remarkable defence that the court had no jurisdiction over cases involving aboriginals, since they should by the law of nature be punished 'in the very way in which they themselves would punish others falling into their hands.' Judge Forbes overruled this claim, but Lowe was acquitted on the ground that the crown witnesses were not to be believed. He then rejoined his regiment, which had meanwhile been transferred to Tasmania.

Lowe, ROBERT. See SHERBROOKE, LORD.

Lucerne, a leguminous fodder-plant native to southern Europe, and taken thence to the Americas by the Spanish conquistadors, was brought to Australia from Chile in September 1827 by John Powditch, master of the *Elizabeth*. By December of that year it was naturalizing itself in many Sydney gardens. In those days it was known as 'alfalfa' (Arabic for 'the best feed'), and the name is still used for it in the United States. Its adoption as a fodder-plant was slow, and confined until late in the 19th century to the alluvial flats of the Hunter, Cudgegong, and Macquarie rivers; on the Hunter eight cuttings were sometimes obtained in a year, yielding about seven tons per acre of dry lucerne hay. The development of irrigation (which suits lucerne well), and the great dairying activity that followed the introduction of refrigerated exports, instigated for a time a steady extension of lucerne-growing in New South Wales and Queensland—the agricultural regions of the other States lying, for the most part, in too cold a climate.

	Acreage.				
	1891	1901	1911	1921	1923
New South Wales . .	20,014	31,491	70,559	70,995	72,337
Queensland .	—	34,117	61,750	53,059	60,042

These figures do not include lucerne grown as a green crop on which stock may be pastured. In the other States there are small areas of lucerne cultivation, notably on the irrigated fields of the Goulburn and Werribee (Bacchus Marsh) schemes: the total acreage in 1923 for all States except New South Wales and Queensland was not quite 32,000, of which 27,000 were in Victoria.

A common tropical weed, *Sida rhombifolia*, known usually as Queensland Hemp, is in some States also called Native Lucerne or Paddy's Lucerne.

Lung-fish. See CERATODUS.

Lutwyche, ALFRED JAMES PETER (1810-1880), born in London and educated at Charterhouse and at Queen's College, Oxford (B.A., 1832; M.A., 1835), after spending a few years as a reporter on the *Morning Chronicle* (where he was a colleague of Charles Dickens) was called to the bar in 1840 and practised as a barrister for about 10 years. For reasons of health he then migrated to Australia, was shipwrecked on the way, and reached Sydney on 30 December 1853. On 12 September 1856 he was nominated to the council and made solicitor-general in the first Cowper ministry (1856), resuming that post in the second (1857) Cowper ministry and transferring to the attorney-generalship in November 1858. In February 1859 he resigned office and his seat in the council on appointment as a judge of the supreme court, and in October of that year was made resident judge at Moreton Bay. Two months later Queensland became a separate colony and Lutwyche its only judge; he therefore expected to be given the post of chief justice, but in 1862 the Herbert ministry fetched James Cockle (q.v.) from England to fill the position. Before this, however, Lutwyche had fallen foul of the ministry. As a New South Wales judge he drew £2000 a year; a Queensland act of 1860 gave him only £1200; and the legislative council, when in 1861 on a hint from London it agreed to restore the larger sum, added a condemnation of the judge for political partisanship and impugning the legality of the constitution. An action for seditious libel which resulted from these proceedings—and had to be tried before Lutwyche himself—assumed importance because it involved high constitutional problems; and the British law officers decided (*a*) that the legislature is not a part of the government, and (*b*) that, whether or no that be so, a seditious libel can be published concerning it. With the arrival of Cockle the dispute calmed down, and in 1866 the two judges collaborated in a revision of Queensland's statute law—though Cockle seems to have done most of the work. Judge Lutwyche died on 10 June 1880.

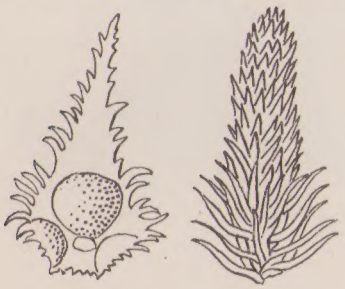
Lycett, JOSEPH (also known as Joseph Lysaght), reached New South Wales in 1810 as a convict, his crime being the uttering of forged notes. He was employed in the police office, but in 1815 was again convicted of forgery and was sent to the Newcastle mines. While there he was allowed to paint an altar-piece for the church then in course of erection, and on the recommendation of the commandant was for this service granted a conditional pardon and allowed to return to Sydney. There he earned his living by painting, and in 1819-21 completed a series of coloured drawings depicting scenes in New South Wales and Tasmania. Three of these—showing a general view of Sydney, the government house at Parramatta, and the government cottage at Windsor—were sent to Earl Bathurst by Macquarie in February 1820. Bigge reported that Lycett's conduct was good, 'but his habits of intoxication were fixed and incurable.' In September 1822 he returned to England—it is supposed that Bathurst paid him for the pictures with a free pardon—and in 1824 brought out in 13 parts a series of *Views in Australia* (advertised as 50 in number, but in reality consisting of 48 views and two maps) with descriptive letterpress; the three given to Bathurst were not among them. The *Views* were republished in 1825 as a single volume. Both the parts and the volume were issued in two states, (*a*) with plates coloured after nature and (*b*) with the plates plain.

Nothing more is certainly known of Lycett, but a MS. note in the Mitchell Library's copy of the *Views* states that he lived for some time in the west of England, forged some notes on

the Stourbridge (Worcestershire) bank, was arrested therefor, and committed suicide rather than stand his trial. See ART.

Lycopodiales. The Lycopodiaceae, Selaginellaceae, Isoëtaceae and Psilotaceae (plants usually known as 'fern-allies') have been until recently classed all together as Lycopodiales. As a result, however, of recent investigations the Psilotaceae (q.v.) must either be brought under the otherwise fossil class Sphenophyllales or constituted a separate class, Psilotales.

Lycopodiaceae (club-mosses) have no ligule at the base of the leaf, and are therefore called Eligulatae; they are included in two genera, *Lycopodium* and *Phylloglossum*. *Lycopodium* is represented in Australia by a number of species of which the principal are the handsome pendent *L. phlegmaria* of northern Queensland, *L. cernuum* (a pan-tropical species spreading from



Lycopodium cernuum.

northern Queensland into New South Wales), *L. laterale*, and *L. densum* (the so-called mountain moss), found in all the States except Western Australia. The characteristic of this genus is that its stem and branches are closely set with simple scale-like leaves, and usually possess terminal cones (strobili) which bear the kidney-shaped sporangia. The prothallium is a tiny tuberous body with a lobed fringe. *Phylloglossum Drummondi*, the single species of that genus, has a mature form very like the embryonic state of certain lycopods; it consists of a tubercle, a tuft of leaves and a stalk which terminates in a cone of sporangium-bearing leaves. The whole plant is very minute and has been considered a primitive form. It is limited, apparently, to Australia and New Zealand.

Selaginellaceae (a family limited to one genus, *Selaginella*) and Isoëtaceae are characterized by the presence of ligules at the base of the leaves. Nearly all selaginellas have their shoots dorsiventrally flattened, and their leaves in four rows —two rows of smaller overlapping leaves right and left of the medium dorsal line, and two rather larger ones along the edges of the stem. The sporangia are spherical, arising in the axils of the fertile leaves (collected into cones) and are of two kinds—megasporangia, with four megaspores, and microsporangia, which contain a large number of microspores. Sometimes the two kinds of sporangia are on different cones. There are several Australian species, the most common, perhaps, being *S. uliginosa;* it is found in all the States, as is also the moss-like *S. preissiana*. *S. australiensis* and *S. brisbanensis* are decumbent plants. *S. longipinna* (better known as *S. flabellata*) is a magnificent species, growing in dense dark-green patches alongside the creeks of northern Queensland. Two other species, *S. proniflora* (*S. Belangeri*) and *S. pumilio*, are also northern.

The Isoëtaceae have generally been linked with the Selaginellaceae under Lycopodiales Ligulatae, but Dr. Campbell considers the Isoëtaceae to be sufficiently distinct to warrant the establishment of a separate order, Isoëtales. *Isoëtes* has a very stunted stem and crowded quill-like leaves. There are no special fertile leaves, and consequently no cone; the stem is deeply grooved on its under surface; the sporangia, which are produced on the leaf, are very large, and contain a much larger number, not only of microspores, but of megaspores, than the allied families. The Australian species known to the writer are *I. Stuarti* and *I. elatior* from Tasmania, and *I. Drummondi* from Victoria.

W.W.W.

Lyne, SIR WILLIAM JOHN (1844-1913), born at Apslawn in Tasmania on 6 April 1844, in 1864 made a trial of pastoral life on the Gulf country in Queensland, but after a year returned to Tasmania and became shire-clerk of Glamorgan. In 1875 he reverted to a pastoral life, taking up land near Cumberoona on the Murray, and in 1880 entered New South Wales politics as member for the Hume (the upper Murray constituency); this seat he held till he left local for federal politics in 1901. Attaching himself to the protectionist party, in which he soon became a leading debater, he was secretary for public works in the Dibbs ministries of 1885 and 1891-4 and the Jennings ministry of 1886-7, and secretary for lands in the Dibbs ministry of 1889; in 1899, after five years of opposition (during which he led the anti-federationist section of the protectionist party), he succeeded George Reid (q.v.) as premier, and thus deprived him of the chance of becoming first prime minister of the Commonwealth. Lyne's career in the New South Wales parliament was marked by 'a singular mixture of good nature and wiliness' (to quote Sir George Reid), and his administration by events which created against him a strong suspicion of undue favouritism. He was undoubtedly a very able parliamentary tactician and, where he was at all friendly, a devoted friend. Though a member of the convention of 1897-8, his known opposition to federation of any kind rendered his influence on the debates of the convention almost nugatory, and the only suggestion by which he is remembered in that connection was one to make Sydney the federal capital—which was treated as a joke. As premier of New South Wales, however, he distinguished himself by proposing to send a contingent of troops to join the British forces engaged in the South African war—the first of many contingents despatched thither, which did valuable work and learnt useful lessons in the art of war. He also attempted to give women the franchise; but the bill was rejected by the council.

When Lord Hopetoun, the first governor-general of the Commonwealth, reached Australia, he was privately advised to offer the first prime ministership to the premier of the senior colony —i.e. to Lyne; behind this advice there was the hope that Lyne, being anti-federalist and little known in the other colonies, would prove an easily ousted prime minister. Lyne found himself unable to get together a sufficiently strong body of colleagues, and had to resign the task to Edmund Barton, who had long since been chosen for the post by an overwhelming public opinion. Barton took his defeated rival into his cabinet as minister for home affairs until August 1903, when on C. C. Kingston's resignation Lyne became minister for trade and customs. This de-

partment he continued to administer in the Deakin ministries of 1903-4 and 1905-8, though during the latter period he succeeded John Forrest as treasurer on 30 July 1907 and handed over the customs to Austin Chapman. As treasurer he carried through the customs tariff act of 1908, the first in which high protection combined with a marked preference for British goods was established as the policy of the Commonwealth.

The story of federal politics from 1903 to 1909 would include that of a persistent struggle between William Lyne and John Forrest for influence over Alfred Deakin. When in 1907 Deakin took Lyne with him to represent Australia at the Imperial conference of that year, it was understood that Lyne had won, and on the delegates' return Forrest left the ministry. But, when in November 1908 the Labour party withdrew that support by which alone the Deakin ministry had existed, Forrest's influence began to augment, and the Deakin-Cook fusion which expelled Labour from office in May 1909 was chiefly his work. Lyne therefore abandoned and bitterly attacked his former leader, and for the rest of his life remained a disappointed and disgruntled man. His work in the federal parliament had been irreproachable, if sometimes unenlightened, and in his last years he gained the sympathy of the bulk of his fellow representatives. He died at Sydney on 3 August 1913. (K.C.M.G., 1900.)

Lyre-birds, large terrestrial birds, constituting the family Menuridae, peculiar to south-eastern Australia. Their size, long legs, and stout toes, give lyre-birds a superficial resemblance to game birds, but structurally they are nearly related to the perching birds. By some authorities they are associated with scrub-birds (Atrichornithidae) in a sub-order called Passeres abnormales. By others they are classed by themselves in an order called Menuriformes.

The family contains a single genus, *Menura*, with two very distinct species. The Superb Lyre-bird (*M. novae-hollandiae*) inhabits the coastal areas from southern Queensland to eastern Victoria, chiefly occurring in forest country with thick undergrowth, especially tree-fern gullies among hills. The Albert Lyre-bird (*M. alberti*) is confined to the tropical scrubs of southern Queensland and the northern rivers of New South Wales; as these scrubs are being destroyed to make room for dairying and fruit-growing, it will probably soon be extinct.

Both sexes are slaty-brown in colour, the female having a long tail of normal feathers. In the male the central tail-feathers have long lateral filaments only, without barbs; the outer pair are curved first outwards, then inwards, and then sharply outwards at the tips. The inner edges of these two feathers are in the superb lyre-bird marked with triangular light-coloured transparent patches, but are uniform in the Albert lyre-bird, whose plumage is more rufous throughout.

The nest is a large domed structure, built in a tree-fern or on a stump; a single purple, blotched egg is laid. The breeding season is the middle of winter—perhaps in order that the young bird may be out of the nest before the destructive goanna wakes from his winter sleep.

Superb Lyre-bird.

The very powerful legs and claws are used in scratching up the ground and turning over logs, etc., in search of the insects, centipedes, crustacea, and snails on which the birds feed.

The cock-bird clears small circular areas in the scrub, and scratches up in the clearing a low mound of earth on which, either alone or before an audience of one or more hens, he sings, dances, and spreads his wonderful tail. Without question the lyre-bird is the best song-bird of Australia, its notes being peculiarly liquid and melodious; nor is there any doubt that as a mimic it is unrivalled throughout the world. Mixed with its song the listener may hear in succession the laugh of the kookaburra, the crack of the coach-whip-bird, the screaming of black cockatoos, the song of the harmonious thrush, the buzz of a circular saw, the whistle of a railway train, the howling of the dingo, and the hammering of nails, all imitated to the life. Indeed, its capacity for imitating any and every sound it may hear in the bush—with the sole exception of human speech—seems quite perfect. The hen bird, though not so powerful a songster as the cock, is also an accomplished mimic.

When first discovered (about 1799) the birds were called 'birds of paradise of New South Wales;' this cumbersome title gave place to the name 'native' or 'mountain pheasant,' bestowed by the settlers and still in use. About 1830 the name 'lyre-bird' began to be used, obviously because the tail is remarkably like the framework of a lyre. W.B.A.
